Dr. C. Heitzmann demonstrated a microscopic specimen of cartilage of the knee-joint of a dog, in which specimen he stated that carbon-granules could be seen within the cartilage-corpuscles, and in the basement substance. This change was produced by touching the articular surface of the cartilage with hot iron, seven days before the animal was killed. The carbon-particles, produced by burning of the cartilage, became transported up to a certain distance around the wound, so that the brown discoloration was not present in the immediate neighborhood of the wound. Such transportations, known to occur also with cinnabar-granules in the cartilage, were not explained for a long time, inasmuch as a basement substance of the cartilage was thought to be a structureless mass. Dr. H. remarked that he had succeeded in demonstrating the presence of a very rich network within the basement substance by painting the latter with nitrate of silver. This, he said, showed the spaces belonging to protoplasm empty; while the painting with a solution of chloride of gold brought to view the cartilage-corpuscles and the uniting network. The presence of living matter throughout the basement substance, explained the possibility of transportation of small foreign bodies, as in the specimen of cartilage exhibited to the Society.

NEW YORK COUNTY MEDICAL SOCIETY.

Stated Meeting, April 24th, 1876.

Dr. H. B. Sands, President, in the Chair.

The following gentlemen were elected members: Drs. P. F. Chambers, A. M. Jacobus, M. R. Vedder, H. F. Hessler, G. W. Ball, —— Ray, W. H. Wright, T. S. P. Miller, J. H. Rudwright, N. C. Levings, —— Clark, and J. J. Henna.

ON THE NATURE OF SUPPURATIVE PROCESSES IN THE SKIN.

Dr. Charles Heitzmann read a paper upon the above subject, which was interesting mainly in the fact that a new theory was advanced with reference to the production of pus corpuscles. Prefatory to the study of the microscopical changes, the doctor referred to the fact that certain persons were liable, in a marked degree, to the development of the suppurative process; that in certain cases union, by first intention, almost never occurred; that in such individuals there was commonly evidence of scrofulosis. In other cases in which the suppurative process was easily developed there existed distinct signs of old pleurisy or pulmonary consumption. In others, again, who were well developed, there was a special tendency to suppurative processes; but upon examining the family connections, evidences of the same tendency were usually found, and more closely associated with scrofulosis. Badly nourished children were specially prone to suppurative processes; and suppurative diseases of the skin were of frequent occurrence in persons whose nutrition was poor. Exhaustive diseases favored the development of suppurative processes — for example, abscesses following typhoid fever. Allusion was made to the fact that there was a notable difference in the tendency in different animals to the development of suppurative processes. For example, in rabbits and guinea-pigs, a peculiar tendency to suppuration was noted, and in those animals the development of artificial tuberculosis was not difficult, whereas in dogs such inoculations rarely succeeded. The general cause of any suppurative process was regarded as probably the same which gave rise to inflammatory processes; and that it manifested itself by changes affecting all the parts of the living tissue, including blood-vessels and nerves. Why such an extensive suppurative process manifested itself in small-pox, could hardly be suspected; and why chronic suppurations of the skin occurred in syphilis, was a puzzle equally as great as the question relating to small-pox. At one time search had been made for small organisms which, when present, would lead to suppuration, but success had not attended the effort. In certain cases, as in pyæmia and erysipelas, there might be a self-infection; and so far as the doctor's own observations had extended in connection with pyæmia, he had found purulent inflammation of the veins, without exception; but why the peculiar secondary manifestations, such as abscesses in the joints, etc. occurred, remained to be explained. Why erysipelas occurred as an endemic and epidemic disease was not known, although Hebra regarded the remote cause of erysipelas as existing in some local purulent formation. Reference was made to the development of suppuration by means of foreign bodies, organic material in a state of decomposition, strong acids and alkalies, heat, etc. The doctrine of a dyscrasia underlying skin diseases was rejected. Dr. Heitzmann here referred to the production of impetiginous pustules upon his own body by scratching. From that he passed to the consideration of the source of pus, as shown by the microscope. After reviewing the different theories which have been advanced regarding the formation of pus, Dr. Heitzmann presented his own, which was, in substance, as follows:

The matter commonly called protoplasm, was said to be built up of a true net-work, formed by masses of living matter, united to each other by delicate, thread-like connections, and suspended, as it were, in a material not endowed with the properties of life. The nucleus was held to be nothing but a compact mass of living matter; and its behavior, when treated with the chloride of gold, was the same as that of other elements of living matter. It was maintained that the matter between what are commonly called cells was not lifeless, but was a substance amply provided with living elements. This view was illustrated by studying the amœba, which had been supposed to be a lump of jelly-like living matter, called protoplasm, containing granules supposed to be foreign elements, but which Dr. Heitzmann maintained were thickened places at the points of intersection of a fine net-work of threads which pervades the whole mass. The animal, according to the new theory, represented a mass of living matter, the denser accumulations of which, formerly called cells, were connected by more delicate thread-like processes of the same living matter; and in the meshes of this net-work is suspended a fluid in which various corpuscles, such as blood corpuscles and pigment granules, might float. As will be seen, the theory supplanted the cell doctrine; for, what have been known as cells, as was claimed, were made up of granules and threads of living matter which unite the nucleolus with the nucleus, the nucleus with the periphery, and the threads permeate the substance between the so-called cells, thus effecting a union one with the other throughout the entire body. What formerly had been recognized as a cell, had no distinct entity, but was simply a fractional part of the innumerable whole. To the development of inflammation, the presence of blood-vessels, either in the part or its immediate neighborhood, was regarded as indispensable. The first step in the inflammatory process was a softening or liquefaction of the glue giving basis substance, and a retrocession to the embryonic appearance of the protoplasm, in which the protoplasmatic elements were again rendered visible. The first step then was a reappearance of the elements which constituted the tissue in its embryonic state. At the second step in the inflammatory process, the living granules, very often the nucleus, increased in size; there was a production of living matter to a certain amount; every such corpuscle, a living granule, increased in size, was capable of producing new elements; and all those elements were united with each other by means of the delicate threads to which reference has been made. That was the second step in the inflammatory process which leads to new formation. Now, if those thread-like connections between the enlarged granules of living matter became torn asunder, as they might from the tension produced by a large amount of exudation; if by any means the single elements were separated, they at once were pus corpuscles.

In the process of inflammation, then, the granules of the protoplasm increased in size, became detached from each other, and were then pus corpuscles. Pus, therefore, was metamorphosed tissue; pus corpuscles were elements of a former tissue separated from each other; pus was not tissue, nor was it capable of producing tissue; a pus corpuscle was a newly-formed protoplasmic lump.

Dr. Heitzmann then alluded to the difference in appearance of pus from a healthy person and from a person with a broken-down constitution. In those run down by starvation, etc., the living matter in a pus corpuscle was a very small quantity, while in a healthy individual the amount of living matter might be so great that the nucleus became invisible. The doctor claimed that he had been able to recognize the constitution of the patient by watching the movements of the pus corpuscle upon the heated stage under the microscope. The pus corpuscle from the unhealthy subject was much more lively than from

the healthy, because the amount of living matter which it contained was much smaller, and mostly in the form of threads.

Finally, said the doctor, "if we will omit such terms as dyserasia and the like, the microscope will be much more valuable in the diagnosis of disease than it is at the present time."

Dr. Andr. R. Robinson supported the theory advanced by Dr. Heitzmann, and believed that the fibrillary structure of living matter enabled us to understand many processes in pathology which previously have not been explained. It was regarded as specially valuable in the study of the formation of pus cells; and he had seen pus corpuscles formed, not only from the white blood-corpuscles, but from the nuclei of the ganglionic cells, and from the axis cylinder.

Dr. Mary Putnam-Jacobi asked Dr. Heitzmann what significance he accorded to the nucleus; did it retain any of its old elements?

Dr. Heitzmann replied that both nucleus and granules were built up of the same matter. It was not necessary that all of these granules should increase in size. On the contrary, many remain without much change. Just the same thing might take place with the nucleus. It was true, if the nucleus were surrounded simply by a shell of living matter, it invariably changed in the living solid body; it does not necessarily divide. But other granules might increase in size in the nucleus. Why that took place is not understood.

Correspondence.

THE DEATH OF LOUIS TRAUBE.

To the Editor of The Medical Record.

Sir:—As in February, by the death of Gabriel Andral, there passed away the great triumvirate of the Paris Medical School, composed of Louis, Chomel, and Andral, so this week records, by the death of Traube, the disappearance of a triumvirate in the Berlin Medical School—Dieffenbach, von Graefe, and Traube. There is a strong analogy in the disposition of the exponents of these respective seats of learning into THREES, while to-day the status of the schools themselves is widely dissimilar.

Traube died of pericarditis, after a lingering illness of many weeks, during the earlier part of which he irregularly appeared in his clinique, and in its latter part, as often happens in such diseases, every hope was entertained of his improvement.

Louis Traube was born January 12, 1818, in Ratibor. He studied in the Universities of Breslau, Vienna, and Berlin; was promoted in the last University in 1840, and took his State's examination the following year. During his ante-graduate years he was at one time a colleague of DuBois-Reymond, Virchow, and Helmholtz. In Vienna he was a most diligent pupil of Rokitansky and Skoda, who, it may be said, gave him the first incentives to those anatomico-pathological investigations which developed ultimately into the use of the thermometer and temperature registration in medicine. For three years after his graduation he acted as assistant to a physician in Voigtland, where with unusual zeal he made the clinical study of diseases of the chest and abdomen his chief pursuit. In 1843 he instituted exercises in auscultation and percussion, collected about him many physicians and students, and freed the new method of exploration, by his accurate physiological and pathological investigations, of many errors. In 1848 he was made Privatdocent in the University of Berlin; in 1849, assistant to the clinique of Prof. Schoenlein, which position he held for ten years. During this time he was assigned to the department of Diseases of the Chest in the Charité, which represented, as it were, an appendix to the Schoenlein-clinique, and gradually developed into a distinct, self-sustaining clinique. In 1858 he refused a call to the University of Heidelberg, as also later similar invitations to Breslau, Zurich, and Bonn. He remained an instructor in the University of Berlin until, in 1872, it saw fit to advance him to the position of Ordinary Professor, in which office he died.

Traube is known to the scientific world as the first one who utilized thermometry at the bedside. By his students he will be remembered for his definite diagnosis, accurate prognosis, and the simplicity of his presence. He was not only a remarkable practising physician, not only a clinical teacher of rare endowment, but also a man of exact scientific inquiry, and standing in the front ranks of reformers in medical, as distinguished from surgical, theories. Though still young, he has occupied for twenty years perhaps the highest position of any consulting practitioner of medicine in Berlin, in the opinion of the public.

The second half of the decade, 1840–50, witnessed here a reform in which Traube played a prominent rôle. It arrayed itself, on the one hand, against formal, dry dogmatism, which was at home in most of the doctrines of the German universities, and against the ultraism of the *à priori* system of the natural philosophy school; and, on the other hand, no less against the experiments made under the leadership of Rokitansky in Vienna, where, until then, no man had dared to express the conviction that pathological anatomy must be the groundwork, not only of medical science, but also of medical commerce; indeed, that it contributes all which goes to make medicine, as a science, positive and fundamental. The new Vienna School displayed a triumphant banner through all Germany; and, strange enough, it encountered harsh criticism from a few hitherto unknown young physicians of Berlin. A part of these young men pursued the studies of physics and physiology, as Helmholtz, DuBois Reymond, and others; while Traube and Virchow devoted themselves to pathology, by experiment and clinical observation. In 1846 Traube's first work, "Contributions to Experimental Pathology and Physiology," was published. After a quarter of a century of work in the same direction, he found no occasion to change his early results. Virchow writes, at this early time, of the independent direction of his experimental study, and of his most accurate methodical investigation. Typhus and pneumonia he studied with the thermometer in his hand. He developed the various actions of digitalis, with which Schoenlein was so pleased that he encouraged the investigation by large uses of the drug in his clinique.

As in diagnosis, so in therapeutics was Traube equally exact, and never tired in busying himself with details in treatment. Naturally enough, he was one of the most successful of teachers, and as a successful clinical instructor is he best known by most of the physicians who during the past twenty-five years have been graduated at this University.

At his funeral, the Medical Faculty, the Charité, the Friedrich-Wilhelms-Institut, several medical societies of which he was a member, and the Ministry of Ec-

clesiastical Education, were represented officially. The burial services were after the Jewish rite, and were attended by a large concourse of physicians and citizens. An immense line of carriages followed to the Jewish cemetery in Schoenhanser Allee. QUANT.

BERLIN, April 14, 1876.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department United States Army, from April 30th to May 6th, 1876.

EDWARDS, S. A., Surgeon.—Leave of Absence extended six months on Surgeon's Certificate of disability. S. O. 84, A. G. O., April 28, 1876.

MAGRUDER, D. L., Surgeon and Medical Director.—Granted leave of absence for one month. S. O. 49, Department of Arizona, April 17, 1876,

WOODHULL, A. A., Assistant Surgeon.—Granted leave of absence for two months, with permission to apply for an extension of one month. S. O. 12, Department of the South, May 2, 1876.

LIPPINCOTT, H., Assistant Surgeon.—In addition to his other duties, to assume charge of the Medical Director's Office, during absence of Surgeon Magruder. S. O. 49, c. s., Department of Arizona.

TAYLOR, M. E., Assistant Surgeon.—Assigned to duty at Baton Rouge, La. S. O. 84, Department of the Gulf. May 1, 1876.

Medical Items and News.

CONTAGIOUS DISEASES.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending May 6, 1876.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.
April 29th.....	0	5	96	6	73	85	33
May 6th.....	0	14	62	4	48	89	20

INTERNATIONAL MEDICAL CONGRESS AT PHILADELPHIA.—The Medico-Chirurgical Society of Montreal has elected Drs. R. T. Godfrey, W. H. Hingston, George E. Fenwick, R. P. Howard, George Ross, E. H. Trenholme, and John Bell delegates to the Congress.

In addition to the distinguished visitors to the Congress previously mentioned, we learn that Prof. Lazarewitch, of the University of Charkolf, Russia; M. Warlomont, General Secretary of the International Congress of Medical Sciences, at Brussels; Mr. Thomas Joliffe Tufnell, President of the Royal College of Surgeons of Ireland, and Dr. Lauder Brunton of London, Editor of the *Practitioner*, have expressed an intention to be present.

GERMAN SURGICAL SOCIETY.—At the meeting of the Fifth Congress of the German Surgical Society, papers were read by Esmarch on the antiseptic treatment of wounds in military service; by Berns, on Lister's treatment of wounds in Freiburg; by Trendelenburg, on a new apparatus for the antiseptic closure of wounds; by Burchardt, on a modification of Lister's dressing; by Graf, on cotton and tannin dressing; and by Burow, on the open treatment of wounds.

PROFESSOR MERKEL, of Leipsic, long known as an instructor in laryngology, recently died at an advanced age.

DR. MORITZ KÖRNER, of Graz, died upon the 12th of April, after a short illness, in the 56th year of his age. He was Professor of Special Pathology and Therapy, and was regarded as one of the most gifted men and earnest workers in the university.

FEMALE EDUCATION IN ST. PETERSBURG.—The Commission appointed to consider the advisability of establishing a course for women at the University of St. Petersburg has expressed itself as opposed to the project.

LORAIN.—The pupils and friends of Lorain have united in an effort to secure a marble bust of their preceptor, for presentation to the medical faculty. The subscription is signed, among others, by Jeoffroy, Lépine, Prevost, Claude Bernard, and Marey.

NEW YORK EYE AND EAR HOSPITAL.—Since the Manhattan Eye and Ear Hospital began its work on the 15th of October, 1869, fourteen thousand seven hundred and eighty-three (14,783) indigent persons have been treated in its dispensary and wards; and, during the same period, two thousand nine hundred and sixty-four (2,964) important surgical operations have been performed upon the Eye, Ear, and Throat. During the year ending December 31, 1875, three thousand two hundred and thirty-one (3,231) patients were treated and seven hundred and four (704) operations performed. The daily average number of persons treated at the dispensary was fifty-seven (57). The whole number of patients treated as hospital inmates for the year was two hundred and thirty (230). The number of days' board furnished to these patients was two thousand eight hundred and ninety-eight (2,898). Notwithstanding the unparalleled monetary stringency the Hospital has not only been enabled to continue its beneficent work, but to lessen the burden of its indebtedness. The purpose of the founders of the Hospital was to develop an Institution in the centre of the city which should meet the necessities of the poor. To this end the plot of ground 100 by 80 ft. was secured at the very focus of the city railways, that easy access might be had by the thousands of poor who would resort to its Dispensary and Wards. The site alluded to is the best for the purpose on New York Island. The professional staff of the Hospital consists of fourteen medical men: C. R. Agnew, M.D., D.B. St. John Roosa, M.D., O. D. Pomeroy, M.D., C. I. Pardee, M.D., Andrew H. Smith, M.D., Beverley Robinson, M.D., F. R. Sturgis, M.D., David Webster, M.D., F. H. Rankin, M.D., D. R. Ambrose, M.D., G. W. Chamberlain, M.D., G. F. Carey, M.D. C. S. Bull, M.D., Pathologist; W. Cheatham, M.D., House-Surgeon.

SEATS FOR SALESWOMEN.—The ladies of Manchester (England) are urging upon shopkeepers the propriety of providing seats for their saleswomen when not engaged in serving customers. For reasons which are obvious to medical men, the appeal should be heard, not only in Manchester, but in every other place where saleswomen are employed. Why not start such a petition here?

THE ODOR OF IODOFORM.—A correspondent asks what will destroy the odor of iodoform, and refers to the following pitiable situation of one of his patients who is using it: "I am treating a patient with chancroid, who wishes for concealment at his business. He is in close contact with others, and every

now and then he is startled with the expression, "Who has a chancre in this crowd? I know iodoform by its smell. Its odor is a complete tell-tale." Who can help the poor sufferer out of his difficulty?

THE PHYSICAL EFFECTS OF "COCA."—At a recent meeting of the Edinburgh Botanical Society, a paper was read by Sir Robert Christison on the restorative and curative effects of the coca leaf of Peru (Erythroxylon coca), which has for many years been valued by the Indians as a preventive of bodily fatigue, and which has lately attracted much attention, owing to a belief that it was of some service to the American pedestrian, Mr. Weston, on the occasion of some of his walking feats at the Agricultural Hall. A diversity of opinion exists as to the effects of the coca leaf on those who chew it. By some travelers it is maintained to be a pernicious stimulant, while others hold the opinion that, moderately used, it is beneficial to health. Of its effects Sir Robert Christison gave an account, ascertained by experiments he had made himself with a coca leaf, by which he had found that it was both a preventive of fatigue and a restorative of strength after severe bodily exertion, and that it had no reactionary effect on the system. His first experiments made with the leaf were in 1870. Two of his students had come home thoroughly tired out with a sixteen-miles walk; instead of having dinner they each took an infusion of two drachms of coca; presently all signs of fatigue vanished, and they "promenaded" Princes street for a whole hour with ease and enjoyment. On returning home they ate an excellent dinner, felt light throughout the evening, slept well, and got up refreshed and active next morning. Similar results were obtained in the case of other ten students, some of whom had done a thirty-miles walk; and Sir Robert has also made experiments upon himself with a coca leaf of an equally successful nature. He is, it seems, overwhelmed by letters from all quarters asking for information respecting it. Women especially, having tried every other form of narcotic and stimulant, are very anxious to begin with the coca leaf. One lady who has written to Sir Robert Christison on the subject, "put her question in such a shape that he saw plainly that she meant to ask whether it would renew her youth."

THE DAWSON AND PIFFARD BATTERIES.—The committee from the New York Medical Journal Association to report upon the relative merits of the batteries offered by Drs. Dawson and Piffard has been announced, and consists of the following named gentlemen: Dr. J. W. S. Arnold, on the part of Dr. Piffard; Dr. A. McLane Hamilton, on the part of Dr. Dawson; and Dr. John J. Mason, on the part of the Association.

FACULTY PRIZES.—At a recent meeting of the Faculty of the College of Physicians and Surgeons of the City of New York, it was voted to discontinue all Faculty prizes, and in their place to award three prizes for general proficiency in examination: a first prize of one hundred dollars; a second prize of fifty dollars; and a third prize of twenty-five dollars.

POST-PARTUM HEMORRHAGES.—A very simple and efficient method of arousing an inert uterus to contraction is to dip the end of a towel in cold water and smartly slap the hypogastrium. Prof. Isaac E. Taylor, with whom the plan of treatment originated, says that he never saw it fail when properly carried out.

THE BRITISH MEDICAL ASSOCIATION has been invited to hold its next session in Sheffield, instead of Brighton.

STROMEYER'S FIFTIETH PROFESSIONAL ANNIVERSARY, recently celebrated in Hanover, was a great success. The Dublin *Medical Press* says:

"For days before the eventful one, each train which arrived at Hanover brought some of the *élite* of the medical profession from some part of Germany. On the eve of the day several hundred people assembled before his (Stromeyer's) house to sing and repeat eulogies in his honor. Early on the morning of the 6th, he received an autograph letter from the Emperor of Germany, accompanied with a magnificent vase. The order of Red Eagle was presented him by Prince Albrecht from the Emperor. Telegrams from all directions, even from China, arrived, carrying congratulations; and deputations from the various universities of Germany and from England presented addresses. At five o'clock an excellent dinner was provided; three hundred covers were laid. Stromeyer was supported on his right by the Governor of Hanover, and on his left by the President of the German Parliament." It is a very pleasant thing to note such a recognition of distinguished professional services.

SIR WILLIAM ROBERT WILDE, Surgeon-Oculist in Ordinary to her Majesty in Ireland, died at Dublin, April 19. He established the first hospital for ophthalmic diseases in Ireland forty years ago, and at his own expense. His famous work on Aural Surgery has been translated into several languages. He was knighted in 1848 for distinguished professional services.

PEDESTRIANISM AND VERTIGO.—The success of Mr. Weston's recent walk at Birmingham (Eng.) was marred by the occurrence of vertigo. The *Lancet*, in referring to the latter condition, is "convinced that such exhibitions of endurance are made at great risk, and are difficult of justification. Walking is a natural thing, but walking 150 miles in 38 hours is not according to nature."

MEDICAL EDUCATION IN GREAT BRITAIN.—The *Students' Journal and Hospital Gazette* (London), after alluding to our criticism upon the cumbrous systems of medical education in Great Britain, and the necessities for reform, says: "We commend these words to our medical reformers as showing how our systems are judged of by impartial critics across the Atlantic, and as giving some evidence of how ridiculous we should appear could we 'see ourselves as others see us.' It is, indeed, time that some steps were taken to place our system of medical education on a better basis, and do away with the ridiculous system which allows the registration of half qualifications, and encourages the competition of nineteen examining bodies."

ARSENICAL WALL PAPERS.—Out of twenty-one specimens of room paper, Dr. Hodges, analyst for the county of Antrim, found fourteen of them to contain arsenic in large quantities.

THE SULTAN'S MEDICAL STAFF.—The medical bills of the Sultan amount to £28,000 yearly. The visit of the doctor to his august patient is made in great state; he is preceded by an officer carrying a huge sword, while two others, armed to the teeth, march by his side. Notwithstanding the impressiveness of the ceremony, the doctor and his attendants are in winter often snowballed as they pass through the court-yards. Comment is unnecessary.

NURSE-TRAINING.—It is proposed to found a school and hospital for the proper training of nurses in London. Miss Nightingale asks for £20,000 and an income of £5,000 for the proper carrying out of this

scheme. This sum will permanently endow a hospital of one hundred beds.

Cremation.—A cremation society at Dresden proposes to hold a congress in that city on the 6th and 7th of June, when various experiments will be made. The advocates of cremation are chiefly to be found in Holland, one society alone at the Hague numbering 1,300 members. Holland is determined to keep up its reputation for ovens.

Nasal Catarrh Treated Locally.—Mr. W. Spencer Watson. (*Lancet*, April 22.) in referring to Dr. Ferrier's communication, "How to cure Cold in the Head," speaks very highly of the good effects of tobacco snuff. The first pinch generally excites sneezing, but after the second and third pinch the powder remains in the nostrils, and forms a coating for the mucous membrane. A flow of thin serum then begins, and the sense of fulness and obstruction at once subsides. In a few hours the cold is cured, or at the latest survives only a single night. The snuff should be used freely, and the coating formed by it on the mucous membrane should be left undisturbed for several hours, blowing the nose being meanwhile avoided, until all feeling of "stuffiness" in the nostrils has subsided.

Small-Pox Hospitals.—The medical profession at Lyons, France, are not in favor of establishing small-pox hospitals. It is a common practice to admit variolous patients into the wards of general hospitals. The Lyons people deserve to be "pitted."

Fork Swallowing.—On the 15th of April last M. Labbé performed gastrotomy at La Charité for the extraction of a fork which had been swallowed by a young man two years before, in a frolic. The presence of the fork was recognized in the stomach in an oblique position, with the prongs directed toward the cardiac extremity. The patient suffered no inconvenience from the foreign body until a few months before the operation. The Paris correspondent of the *Medical Examiner*, London, under date of April 20, completes the history of the case from this point: "He complained of a continual pain in the left hypochondrium, and was gradually losing his appetite and strength. The fork was in the same position, lying obliquely across the stomach. Surgical intervention was then judged necessary. M. Labbé at first intended to produce adhesive inflammation between the tissues of the epigastric region and the stomach; and several applications were accordingly made, but the desired result was not obtained. Gastrotomy was therefore performed on Saturday last by M. Labbé, assisted by M. Gosselin and Baron Larrey. After opening the peritoneal cavity, the surgeon incised the stomach with a bistoury, and the fork was found in the position above described. What will be the final result of the operation, I cannot tell now; but I have just learned from M. Labbé that the patient is going on well, and that his recovery is most probable. A clinical record of this interesting case and of the operation will shortly be communicated to the Académie de Médecine. This is not the first case in which a fork has been accidentally introduced into the stomach. The first instance is recorded in the *Journal des Savants* for 1716. Sédillot published in his 'Contributions à la Chirurgie' the history of a woman who had swallowed a silver fork, and retained it seven months in the stomach. Gastrotomy was performed by Cayroche, a surgeon of Mende, and the patient was completely cured twenty-five days after the operation. Fedeli extracted from an abscess in the right hypochondrium a fork which had remained for two years in the alimentary canal. Schwab performed the operation of gastrotomy in a young woman twenty-four years old, and extracted a fork which had been 229 days in her stomach. M. Baillarger has reported in a recent number of the *Union Médicale* the case of a lunatic who lived six years with a tin fork in the stomach without feeling any inconvenience, except when making violent movements. After his death, which happened from other causes, the fork was found blackened and imbedded in food. Some thirty years ago, a mountebank, who was in the habit of putting different objects down his throat, let a fork slip into the stomach; the foreign body was immediately removed by the mouth by means of forceps. As may be seen from the cases thus briefly related, forks introduced into the stomach have been removed by very different procedures: 1. By gastrotomy; 2. By the mouth with forceps; 3. Through an abscess produced by adhesive inflammation of the walls of the stomach; 4. By the anus, without any medical or surgical interference."

Children's Hospitals are to be established in Spain, supported, as here, by voluntary contributions.

Lady Students will not be admitted to the University of Prague.

Immorality in a Public Institution.—Dr. Fleming, the founder, and for many years the director, of the Institution for the Blind at Hanover, has been found guilty of immoral conduct towards his emale pupils, and has been sentenced to nine years' imprisonment and a loss of civil rights for five years.

Small-Pox in Bombay.—There is an epidemic of small-pox in Bombay, and the town council has voted for compulsory vaccination.

Cholera.—The Prussian government has created a Cholera Committee, to deliberate on the measures to be taken in the event of an outbreak of the disease.

Yellow Fever in Rio Janeiro.—The deaths from yellow fever in this place average fifty daily.

Dr. Janeway on Discussion of his Paper on Leucocythæmia.—Dr. Janeway writes: "In the discussion on the paper on leucocythæmia, I am quoted (page 306) as saying that 'the existence of splenic and glandular enlargements and the entire absence of blood changes,' etc.

"It should read: 'that the existence of splenic and glandular enlargements in the two diseases, leucocythæmia and pseudo-leucocythæmia, with marked increase of white globules in the former, and the absence of such increase in the latter disease, presents a condition which we cannot at present explain.'"

Weekly Bulletin of the Meetings of Medical Societies.

Saturday, May 13.—N. Y. Medical and Surgical Society.

Original Communications.

THE ADVANTAGES OF THE COTTON PESSARY.

By R. A. PAGE, M.D.,

WASHINGTON, D. C.

The interesting article of Dr. James D. Trask, in the Record of May 6th, together with the approval which the cotton pessary has received from the profession generally, prompts me to report the results of its further use, and to describe some of the modifications and improvements which have since been made in it.

I now make the pessary with a more delicate shaft, not so thick at the extremities, not so long, and roll it more compactly, making it four inches long, and the extremities about one inch and a half in diameter. The manner of making it, as described in my article in the *New York Medical Journal* of Jan. 1876, has been improved by lessening the width of the prepared piece of cotton to six inches, and by thinning out a space two inches wide along the middle of the piece; this leaves a thin layer through the centre of the piece, which, when the cotton is firmly rolled on the thin rubber rod and tightly wrapped, makes a very delicate isthmus. A curved rod of hard rubber one and a half inches long and $\frac{3}{16}$ of an inch in diameter is now used.

As an improvement, suggested by Prof. A. F. A. King, I have dipped the pessary in a solution of caoutchouc (by either bisulphide of carbon or chloroform), which deposits a thin, elastic, and durable film of rubber smoothly over the surface of the instrument. When it is desirable to retain the pessary for a number of days, and in cases where local medication of the cervix is not necessary, this addition to the instrument is a valuable one. The thin film of rubber protects the cotton from the vaginal and cervical secretions, adds to the elasticity of the instrument, and does not affect the consistency and smoothness of the extremities.

In the many cases of vagnal hyperæsthesia and extreme tenderness of the uterus associated with displacement, when hard rubber, silver, or any other instrument of comparatively hard material could not possibly be tolerated, the cotton pessary has invariably been retained and worn so entirely without discomfort, that patients frequently tell me that they forget its presence in the vagina.

The three following cases will serve to show the application and use of the pessary in cases of prolapsus, ante- and retroversion:—

G. W., aged 25, has had two miscarriages. Complained of constant lumbar and sacral pains, sensation of weight and dragging, referable to the pubes; vesical tenesmus, constipation, and hysteria. Able to go about her room. I found upon examination prolapsus of the uterus in the second degree, cervical hyperplasia, great erosion of the face of the cervix, and profuse cervical and vaginal discharge. She was directed to use copious injections of water as warm as could be comfortably borne, for fifteen minutes night and morning, and to remain in bed. The injections greatly relieved her pains, and the vaginal discharge had considerably decreased on the third day, when I applied, through a Sims' speculum, a cotton pessary, after saturating it with carbolized glycerine. One end of the pessary was placed against the cervix and gently pushed into the vagina until it had well passed the sphincter. From the curved form of the pessary, the lower extremity, extending a little beyond the vaginal axis, found its place against the pubes, where it was held while the speculum was withdrawn. The patient was then allowed to get out of bed, and said that she experienced, for the first time in six months, relief from the abdominal and lumbar pains. She was directed to remove the pessary at bed-time, and take injections of hot water. After inserting it for her several times, and instructing her as to its introduction, she used it herself, and from the first application of the pessary was able to go about, in and out of doors, with perfect comfort. For three months she used these instruments constantly, and at the expiration of that time was sufficiently relieved to abandon it. During this time the dysmenorrhœa, which periodically intensified her suffering, had been less severe each month, and normal menstruation was finally restored. In connection with the local treatment, remedies to relieve the constipation and general debility were used.

Mrs. E. J., aged 29, has one child. Miscarried one year ago, since which time she has had more or less uterine derangement. First saw her in an attack of acute metritis, and afterwards treated her for complete anteversion, which I found subsequently. I placed the uterine extremity of the pessary in the location of the anterior cul-de-sac, and engaged the other end inside the pubes. The patient was instructed as to its introduction; wore it for ten weeks, when she ceased to wear it constantly, only introducing it as a precautionary measure, when she had work to do which required more than usual exertion.

Mrs. F. has five children; has been in ill health for three years; treated during that time for lumbago, rheumatism, and sciatica without relief. Her physicians had made no vaginal examination, and therefore did not discover the source of her suffering. Complete retroversion—slightly lateral; thickening of the anterior wall of the cervix and fundus, with an interstitial fibroid in the latter; dysmenorrhœa; constant pain in back and hips; numbness of the thighs; and profuse leucorrhœa. After the use of warm-water injections for a day or two, the pessary was inserted, one extremity thrust in the posterior cul-de-sac, the other end supported at the pubes, as in the other cases. The patient's husband has been taught to use the Higbee speculum, and, through it, daily introduces the instrument for her. This lady is entirely relieved of the numbness in the thighs, and the pain at the sacrum; the discharge has very much decreased, and she is able to walk long distances—an impossibility previous to the institution of this treatment. The general health of the patient is very much improved; and were it not for the fibroid and increased weight of the uterus, I have no doubt she would, in a short time, be able to dispense with the pessary.

On removing the pessary at night, it is placed in a solution of carbolic acid during the night, and reanointed in the morning with glycerine before it is replaced. One instrument is used in this way two days, after which it is allowed to soak in the acid solution for two days, while a new pessary is being used, and can be used again. Among the poorer classes who manage in this way, a few pessaries will last a long time. I have carefully examined the instruments treated in this way, and have yet to discover the slightest fetor.

In many cases where a permanent support was necessary, I have prepared the parts for the ultimate introduction of the Hodge or Higbee pessary, by using, at first, this unirritating support, overcoming, gradually

the vaginismus and extreme tenderness, by its daily introduction, and rendering them at last tolerant of a harder instrument. I have had many patients whose uteri had become so irritated and sensitive from wearing various forms of hard pessaries, that at first they were almost unable to bear the introduction of the soft cotton.

Dr. Trask, of Astoria, L. I., after reporting the excellent success which he had in the use of a pessary made according to my description in the *New York Medical Journal*, suggests a new mode of applying them, and that they can be made with advantage, of soft rubber. I have no experience in the method of applying it. Dr. Trask applies the pessary so curved that the ends are fitted in the anterior and posterior cul-de-sacs; in this he depends upon a tonicity of the vaginal walls, which is not found generally in cases of displacement, or the vagina has to be distended sufficiently to tightly hold the instrument. In the latter case the rectum and bladder must be considerably impinged upon. This seems to me to be an objection to this mode of applying it. Dr. Gaillard Thomas recommends the placing of cotton balls in front and back of the cervix, which for the same reasons are not easily retained—a complaint made by Schroeder. The plan of Dr. Trask, if the instrument can be retained in that position, gives the uterus more support than the balls of cotton. The cervix is made to rest upon the curved isthmus of the pessary, by placing the extremities in the anterior and posterior cul-de-sacs; but as far as my experience goes, a pessary of whatever material, so long as it be of the dumb-bell form, would be of most service applied in the manner which I have described for the application of the cotton instrument.

Dr. Trask's desire to have them made of soft rubber, probably originated in his objection to the time and trouble required to make the cotton pessary properly, and to the fact that they had to be constantly renewed. These, I admit, would be formidable objections were it necessary for every physician to make them himself; but when I gave the results of my experience with this instrument to the profession, it was with the hope and belief, that, if others had the excellent success in its use which I had, it would be taken up by the manufacturers, and made in such quantities, and at such a small cost, that it could be procured like any other instrument which is constantly in demand.

Whatever the advantages of other material may be, the soft, clean cotton has in my experience given such good results, combining as it does unirritating support, and the opportunity for local medication, that I prefer it to anything else, notwithstanding the time and trouble involved in its preparation, and the necessity for its frequent removal.

The latter objection, however, is entirely removed by the use of a covering of thin rubber cloth, as manufactured by Messrs. John Reynders & Co., New York.

NOTES ON DIPHTHERIA.

By E. R. MAXSON, M.D., LL.D.,

Syracuse, N. Y.

When I first ventured to classify diphtheria as a "general febrile affection," in 1861, though fully convinced that its pathology demanded it, I had no little misgiving as to the manner in which it might be received by the profession, and especially those who had written upon the disease, who had, as far as I know, invariably treated it as a local throat affection, liable only to accidental general complications, of a febrile or other character.

But a very general acquiescence by the *best writers*, in this country and abroad, in the classification, as I thought, on strictly legitimate principles, relieved my mind. The *North American Medico-Chirurgical Review*, then ably edited by Prof. S. D. Gross, I believe, referred to the fact, without comment; and the late Prof. S. H. Dickson assured me that I was "right," and that he had only treated of diphtheria as a *local* disease, "in accordance with the universal custom, as a matter of convenience."

And I may further add, that my convictions as to the true pathology, and hence, proper classification of diphtheria were arrived at, after carefully tracing the history and progress of the disease from its origin in Egypt, more than two thousand years ago; extending only into Asia Minor during the first five hundred years; then invading the south of Europe, and crossing the Continent during the next fifteen-hundred years, affecting principally garrisoned towns—till, reaching Paris, London, and Liverpool, it passed to various other parts of the world, including our own. In addition to this, it had been my lot to be brought in contact with the disease in all its various forms and complications; as the village and vicinity of Geneva, in this State, where I was located, had for a few years preceding 1861, been the theatre of perhaps more diphtheria than any other on this continent, and, so far as I know, in the world.

My observations since 1861, and conversation with prominent pathologists, in this country and abroad, have confirmed me in the position I then took: "That *diphtheria is essentially a general putrid fever, analogous to, and belonging with plague, typhus, etc*," and not properly, as its name would imply, a merely local throat affection; or in any degree analogous to croup, but invariably the result of *contagion*; or else of introduction into the blood, through the skin, stomach, or lungs, of *animal* or *marsh miasms*, probably as cryptogamous plants, or microscopic animalcules, or both, —call them *bacteria*, or whatever the fancy may dictate—the blood in every case becoming contaminated, and undergoing more or less local or general decomposition; and hence the *fibrino albuminous exudations*, of various degrees of organization, on the mucous membranes of the air-passages and alimentary canal, as well as on the lining membrane of the heart, arteries, veins, etc, as I have witnessed—one marked case of which was the patient of my friend Dr. J. D. Smith, of Geneva, N. Y., which was examined in the presence of several prominent physicians of that town. And within the past month I have witnessed, in this city, the expulsion at one time by a boy fifteen years old, on the fourth day of the disease in a malignant form, at stool, what appeared to be one continuous membrane, from the entire length of the alimentary mucous membrane, measuring about a pint.

In this case, the disease was evidently produced by *miasms* generated in an immense heap of decomposing animal and vegetable matters, near the street he passed, in the outskirts of the city, on his way to school. The disease was rapid in its inception and progress, perfect casts of the anterior nasal passages having been expelled two days later by violent efforts; the larynx having been kept comparatively clear by the constant spasmodic vomiting kept up from the first, which I was unable to control; the forcible expulsion being attended with quite profuse hemorrhage.

This case has recovered, and, though I gave him cincho-quinine, the tincture of chloride of iron, carbolic acid, milk-punch, &c., I am inclined to think that, except for the spasmodic vomiting, which I could not control, he might have suffocated before the general remedies could have been brought to bear in correcting the general condition. And this reminds me of the fact that I once saved a child in Geneva, six years old, by vomiting it, several times a day, when about to suffocate, for nearly a week; keeping up, as I did in this case, the tonics, stimulants, gargles, etc.

In cases of diphtheria produced by putrid animal and vegetable exhalations, I do not believe the *miasm* is generally of sufficient concentration to develop the *fibrino-albuminous* exudation, by the local decomposition of the blood of the part, independent of, and before its general contamination and decomposition; but the *contagion* from malignant cases, brought in contact with a mucous membrane or even abraded skin, may be so concentrated as to produce the local manifestation of the disease before there is any apparent contamination of the general system; though, unless counteracted, it rapidly follows, if it does not always precede, as it generally does, though perhaps unnoticed, in some very rare cases, through inattention. I once attended a lady in her first confinement, while I had under my care cases of malignant diphtheria; and though I took what I regarded as the proper precautions, the diphtheritic membrane developed rapidly, upon the mucous membrane of the vagina and the external genitals, without much apparent general contamination of the system. She took milk-punch, and the membrane was rapidly removed by proper local applications, as strong sage tea, with alum and borax; and though the lady herself appeared to suffer but little, having a good recovery from her confinement, the babe died in two days of malignant diphtheria, and her nurse, a young woman, in about one week, with no other apparent exposure.

I have just had, however, a marked case, tending to show that what may appear like a purely local, is really a general affection, demanding corresponding treatment.

A young woman of seventeen, in the same house with, though kept apart from, a malignant case of diphtheria, disinfectants having been freely used, had excessive irritation of the mucous membrane of the anterior nasal passages, attended with a thin sanious discharge, which kept up for several days in spite of the usual applications, including carbolic acid in water, etc. She had a good appetite, and followed her usual vocations of household duties, study &c. After about one week the tonsils swelled, and a diphtheritic membrane appeared upon them, the nasal irritation still keeping up and being attended with the discharge. As she appeared quite well, I still gave her only gargles of carbolic acid in water, muriate of ammonia in vinegar and water, sage tea, with alum and borax, etc., with no apparent relief; and though she still appeared quite well, I then gave her cincho-quinine, the muriated tincture of iron, whiskey, and improved cathartic pills, when the membrane rapidly disappeared from the tonsils, the nasal irritation subsiding, as well as the discharge ceasing, the gargles being continued.

It is likely, then, that in those cases, apparently *local*, there is generally, if not invariably, more or less general putridity of the blood, leading to the general and local febrile and inflammatory symptoms which are developed, rendering diphtheria, emphatically, *a general contagious putrid febrile affection*, as foreign from croup as any general putrid fever can possibly be from a simple benign inflammatory fever; the exudation in membranous croup consisting of fully organized, uncontaminated *fibrino-albuminous* matter, and purely the result of a simple sthenic inflammation; while in diphtheria it is more or less imperfectly organized, being the product of partially decomposed blood, and attended with more or less *passive* inflammation, congestion, and a general asthenic febrile condition, *continued* or *remittent*, as the *animal* or *marsh miasm* may have predominated in producing the disease in each particular case; the *animal*, in my opinion, being an *essential*, and the *paludal* a frequent additional cause, carrying its peculiar characteristics, and increasing the malignancy, as I have often noticed.

I was first led to the use of *milk-punch* in diphtheria, from finding a diphtheritic membrane, expelled from the trachea of a child, all *dissolved*, in a few days, in the alcohol I had put it for preservation; inferring that if it would *dissolve*, it might tend to *prevent* the organization of the membrane, as well as to arrest the decomposition or fermentation of the blood, as it is well known to do to various animal and vegetable matters. And, while I now have great confidence in quinine or cincho quinine, the tincture of chloride of iron, carbolic or salicylic acids, gargles, and plenty of nourishment, especially *milk*, I still regard *milk-punch*, in quantities adapted to each particular case, as indispensable in the treatment of diphtheria. And, *to clear the nose or throat* of the sanious, viscid, or half organized putrid exudations, so annoying and dangerous to the patient, I prefer by far, *warm milk*, snuffed up the nostrils or used as a gargle, to any other liquid. It soothes; and, uniting with, aids in the expulsion of the detached collecting matters, more than anything else I have found.

No. 208 Madison Street, Syracuse, N. Y., May 1, 1876.

CASES ILLUSTRATING THE POSSIBILITY OF A CONNECTION BETWEEN MALARIAL POISONING AND CHOREA.

By FRANK P. KINNICUTT, M.D.

NEW YORK.

The possible influence of malaria in the etiology of chorea has been suggested by several authors, but the literature of the subject is, so far as I am aware, devoid of any probable *demonstration* of such a causal relationship.

If we accept the view that chorea is essentially a disease of impairment of nervous power, at the same time bearing in mind the well-known enfeebling and depressing effect of malarial poison upon the nervous system, we should, *à priori*, be led to look for clinical evidence of the, at least, occasional dependence of this affection upon a morbid influence of this nature. The non-occurrence of chorea in adults subjected to a prolonged exposure to malaria, cannot justly be regarded as an argument against such a genesis; inasmuch as this disease, from *any cause*, only exceptionally occurs after the age of puberty.

The following cases, which have recently come under my observation in Dr. Seguin's clinique, at the College of Physicians and Surgeons, possess much interest, it seems to me, in view of the above considerations:

Case I.—E. H——, male, aged six. First seen March 4th, 1876. The patient was in excellent health until two months ago, when, without apparent cause, he began to be troubled with "night terrors," and to seem

and feel poorly. A week since, his mother noticed a slight apparent loss of power in the lower extremities, with disorderly movements of the upper. These symptoms have increased in degree up to the present time. His speech has also become affected. The mother states that he is decidedly worse every other day. There is no history of rheumatism.

Examination.—There are marked choreic movements of the extremities, with a decided loss of power. He is unable to stand without support, and his speech is affected. The heart-sounds are normal. The patient was directed to take six grains of quinine daily.

March 11th.—There is marked improvement in the choreic symptoms. The affection of the speech has disappeared, and the loss of power is much less marked. He is able to walk without support, and stands firmly on his legs. The mother says that improvement was noticeable within two days after the beginning of the treatment, and moreover that his condition is not as good as two days ago, since which time he has *not* taken the quinine. Treatment continued.

April 8th.—The patient is apparently well. There are no choreic movements, the speech is perfect, and the power in the extremities normal. The mother states that his condition has been equally good for the past two weeks.

Case II.—I. M. F——, female, aged 13. Brought to clinique, January 15th, 1876. There is a neurotic family history. The patient was in good health until five weeks ago, when disorderly movements of the left hand were first noticed, extending a little later to the lower extremity of the same side, and finally involving the left half of the face. There has been a gradual increase of these symptoms, with loss of power in the left upper and lower extremities, up to the present time. The speech has also become affected. There is no history of rheumatism.

Examination.—The patient is decidedly anæmic. There are marked choreic movements, with loss of power, in the above-mentioned situations. The speech is affected. The heart sounds are normal. The usual arsenical treatment adopted at the clinique was prescribed: *

Feb. 26th.—No improvement. The patient has complained for the past few days of feverish symptoms, which she has had at times for the past several months. The mother thinks that the choreic symptoms are decidedly worse every other day. Six grains of quinine, daily, were prescribed.

March 4th.—There is a decided improvement in all the symptoms. Treatment continued.

March 18th.—The patient is much better. The choreic movements have almost wholly disappeared. The strength of the left hand is nearly normal. The speech is perfect.

April 1st.—The patient is apparently well. The power in the affected portions is normal.

April 8th.—There has been no return of the trouble. Ordered ferri et quiniæ citra., gr. iij. ter in die.

Practical Medicine and Pathology.—At the recent meeting of the Faculty of the College of Physicians and Surgeons it was voted to discontinue the five series of four lectures each on special subjects, which have heretofore been delivered in the winter session, and to give the hour to the chair of Practice of Medicine and Pathology.

* Three minims of Fowler's solution, three times a day, to a child of three years and older, to be increased by one minim in each dose every third day, until the first symptoms of arsenical poisoning appear, or the disease begins to yield.

Reports of Hospitals.

BELLEVUE HOSPITAL.

Notes of Practice and Peculiarities of Treatment.

Peripheral paralysis, and paralysis due to cerebral lesion—differential diagnosis.

It has been said that in peripheral paralysis there is loss of Faradic excitability. The case seen, however, illustrated the fact that in certain mild cases there is not necessarily a loss of Faradic excitability. In severe cases, such loss may be complete.

A representative of the past—a case of mercurial stomatitis.

The case was utilized by every clinical teacher, as though it were a Chaldean inscription, and received as a compensation atropia, quinine, and chlorate of potash. Of the atropia $\frac{1}{100}$ to $\frac{1}{50}$ of a grain twice a a day, with from six to ten grains of quinine. The chlorate caused so much smarting that borax was substituted.

Facial erysipelas—notable absence of constitutional disturbance.

The inflammation in this case spread over the entire face and *ears*, which necessitated quite a severe attack, and yet the pulse at no time went above 80. The treatment embraced the use of quinine, tincture ferri, good diet, etc.

Acute articular rheumatism—hereditary transmission of the tendency thereto—cold bath—cardiac complications.

A male patient, æt. 21 years, reported that he suffered from his first attack of acute articular rheumatism when nine years of age, and that his mother suffered from repeated attacks of the same affection. The treatment in his case was essentially the alkaline. The question was raised whether there was any ground for supposing that the cold bath increased the liability to cardiac complications in this class of cases, and was answered in the negative.

Delayed sensation in a case of locomotor ataxia.

A male patient, æt. 42, first felt shooting pains from the spine around through the groin, which after a little time were followed by cramps and darting pains in the legs. Reflex excitability was pretty good, but was so delayed that when the sole of the left foot was pricked, five seconds elapsed before the man sung out, "oh!" and jerked his foot away; while with the right foot, four seconds elapsed.

Unusual manifestation of locomotor ataxia in its early stage.

The first symptom developed in the case before us was paralysis of the bladder. The retention of urine was first supposed to be due to stricture, but no stricture was found. It was then supposed to be owing to paralysis of the bladder, which was present, true enough, but it was only a symptom of the locomotor ataxia, which was soon developed in such a manner as to render the diagnosis unquestionable.

Pleurisy with effusion.—gangrene of the lung.—recovery from the gangrene.

There were items in this case which were interesting and of unusual occurrence. They were developed in

a male patient æt. 95, who first had an ordinary attack of sub-acute pleurisy. After a time, evidences of a cavity were developed upon the same side with the pleurisy, and more marked in front than behind, and the patient began to expectorate fetid and gangrenous material, which continued for about six weeks; at the expiration of that time the severity of these symptoms began to diminish, and finally the characteristic expectoration from a gangrenous lung ceased altogether.

The pleurisy remained, there being some fluid in the pleural cavity, and friction sound above it, although the symptoms of gangrene had disappeared. The treatment was mainly supporting.

A SIMPLE PLAN OF TREATMENT IN A CASE OF CHRONIC DIARRHŒA AND DYSENTERY.

The evidence of the chronic diarrhœa existed in the fact that food passed the bowels in almost the same condition it was introduced into the stomach. The dysentery was secondary to an acute attack, and had lasted for six months. A great variety of remedies had been employed by the patient before his admission to the hospital, but without permanent benefit. He was at once placed in bed, and fed upon milk and cod-liver oil, without medicine; and at the time of our visit he had suffered very much less than at any time since the occurrence of the acute attack. This plan of treatment was regarded as the better one, and a significant remark was that "drugs are unnecessary, when you can do all that can be done by means of rest, change in diet, etc."

PNEUMONIA—PLEURISY—PAUCITY OF RATIONAL SYMPTOMS—MARKED FALL OF TEMPERATURE—WAS THE FALL DUE TO QUININE OR TO THE NATURAL COURSE OF THE DISEASE?

A male patient æt. 38, intemperate; when admitted had been sick one week, and at the time of our visit was in the eighth or ninth day of a pneumonia, as diagnosticated by physical exploration. He was attacked on a Saturday with pain in the right shoulder, which soon extended into the right side and was sufficiently severe to disturb respiration. On the next day he had a chill, and that was the entire history of the case. On admission, the seventh day from the attack, his temperature was 104°F., whereupon thirty grains of the sulphate of quinine were administered, and the following day his temperature was 98⅘°F. The high temperature upon the day of admission was regarded as sufficient to exclude pleurisy, at least as the leading element in the case. The rational symptoms, however, rendered the diagnosis very uncertain. Upon physical examination there were found upon the right side of the chest posteriorly, increased vocal fremitus, dulness, perhaps flatness at the lower portion, bronchial breathing, broncophony, small and large-sized râles, and friction-sound just below where the bronchial breathing was most intense. Vesicular respiration was exaggerated and heard all the way down over the anterior portion of the chest upon the same side. It will be noticed that there was a marked fall in temperature after the administration of a large dose of quinine; and the question arose, was it due to the influence of the quinine? It was believed to be the result of the natural course of the disease, although it could be very easily ascribed to the influence of the drug.

A CASE OF TYPHOID FEVER—QUESTION REGARDING ITS ORIGIN.

The disease occurred in the person of one of the orderlies of the hospital, a man æt. 40 years, and, independent of any medication, was a very mild attack. The age of the patient was one point of interest, and another was the mildness of the attack in an individual of that age, although the symptoms were sufficiently well marked to render diagnosis positive. The important question, however, was: why should this man have typhoid fever? There was no way in which it could have been contracted through the medium of drinking-water. A case of typhoid fever occurred in the ward of which this man was orderly, but it occurred one month previous to his own attack, and was the only case of the disease with which he had come in contact during the season. As far as inference from facts could be drawn, a portion of the poison had entered his system, which had been developed in the body of the patient sick with typhoid fever in his ward one month previously. As far as examination had extended, no defect in the soil-pipes connected with the ward has been found.

AN ACCESSORY PHYSICAL SIGN OF PHTHISIS—A POINT WITH REFERENCE TO INSURANCE POLICIES.

There was heard in the phthisical patient before us, a systolic subclavian murmur upon the right side. When this murmur is found upon the right side it possesses in conjunction with other physical signs of phthisis, a certain value as accessory evidence. A subclavian murmur upon the left side is natural to certain persons, and possesses no importance as a physical sign of disease. This is a point of practical importance in the examination of candidates for insurance policies.

CERTAIN ITEMS IN CONNECTION WITH NINE CASES OF ACUTE ARTICULAR RHEUMATISM.

There were four males and five females. In two-thirds of these cases, no treatment had been adopted before admission. In all the cases, the urine was rendered alkaline within twelve hours after admission. In none of the cases was a cardiac murmur developed under observation. In none of the cases was pericarditis developed.

THE THERMOSCOPE AND THE SURFACE THERMOMETER.

There was a lump on the neck of a child, and the question arose whether any elevation of temperature was present. A surface thermometer was used and reported 93° F. on both sides. A thermoscope was used, and it indicated very plainly that in the lump and the tissues surrounding it, there was marked elevation of temperature.

Progress of Medical Science.

SEPARATION AND DESTRUCTION OF THE PANCREAS, AFTER PERFORATION OF THE STOMACH BY ROUND ULCERS.—The following unusual pathological conditions are reported by Dr. Hanns Chiari, of Vienna, as found at the autopsy of a woman of intemperate habits, fifty-four years of age, the immediate cause of death being a fatty degeneration of the heart. The most important and interesting concerned the stomach primarily. The posterior wall of this organ was the seat of two round ulcers the size of strawberries, through which a communication was established between the cavity of the stomach and the sac of the omentum, the latter constituting a sizable suppurating cavity, the contents of which were prevented from escaping into the peritoneal

sac, by intimate adhesion of the margins of the foramen of Winslow. The lower wall of this sac was in places adherent to loops of the jejunum, and there were openings into this part of the intestine. In this sac, together with other broken-down tissues, was found a mass nearly five inches in length, and entirely separated from all other parts. This, on examination, proved to be all that was left of the pancreas. The author considers the ulceration of the coats of the stomach to have been the first step in the morbid process.—*Wiener med. Woch.* March 25, 1876.

On the Relation between Phosphoric Acid and Nitrogen in the Urine.—We quote, from Dr. W. Zuelzer, of Berlin, the following brief summing up of his own conclusions on the subject. In support of them, he furnishes very numerous tables of comparison and observations of the action of various remedies and in various diseases. 1. The relations between phosphoric acid and nitrogen in the urine is under normal circumstances constant, but when subject to different influences, variable. 2. The fluctuations in this relation are characteristic of the periods of advance and decrease of the conversion of tissue in the nervous substance. 3. The general metamorphosis of tissue (of the "flesh") is dependent upon the nervous activity.—*Virchow's Archiv.*, March 28, 1876.

On Parasitic Growths in the Human Lung.—Dr. Paul Fürbringer, of Heidelberg, has arrived at the following conclusions regarding the growth of fungi in the lungs. 1. Their seat is only in diseased portions of the parenchyma, and they are to be regarded as a secondary affection. 2. Stagnating blood, and the products of its decomposition, furnish a favorable soil for the development of fungi. 3. Acute affections of the lungs, occurring in those of healthy constitutions, exclude these growth, while the opposite conditions of chronicity and cachexia favor it. 4. The presence of putrid decomposition appears to prevent the formation of mould-fungus, while that of the schizomycetes, especially bacteria, goes on. 5. The clinical diagnosis of this condition will depend upon the discovery of the germs of the fungus in recently expectorated sputa.—*Virchow's Archiv.*, March 28, 1876.

Watson's Operation.—Some two years ago Dr. Patrick H. Watson, of the Royal Infirmary of Edinburgh, reported the history of an operation which he called "Excision of the Anterior Tarsus and base of the Metatarsus." The operation consists in cutting into the foot upon the inside and upon the outside, dissecting the tissues from the dorsal, and from the plantar surface, and by disarticulating and the use of the saw removing the affected bones in mass. After the operation, and before removing the tourniquet, the entire wound is plugged firmly and securely by means of pledgets of lint, passed through and through the gap in the foot, and laid in closely one upon the back of the other, so as to completely fill up the aperture; and at the same time so closely crowded together as to secure, when pressure is applied from the outside by other pads supported by a bandage, that no bleeding takes place. Dr. W. W. Dawson, of Ohio, gives an account of a similar operation which he performed on a little girl of seven years. Eighteen months previous to the operation, she was struck on the dorsum of the foot by a broom-stick. The blow did not seem to be a hard one, but violent inflammation followed it, involving first the soft structures, and passing thence to the tarsus. After a time the superficial inflammation upon the dorsum of the foot disappeared, but the ostitis remained, together with great thickening of the soft tissues of the plantar surface. When first seen by Dr. Dawson, three months previous to the operation, there was a circumscribed abscess on the inner border of the foot. On the floor of this abscess the tarsus was found to be in a carious condition. Another abscess was formed to the distal side of the first; and after this was opened, the junction between the tarsus and metatarsus was found involved in the disease. Dr. Dawson considered this a fair case for the tunnelling operation suggested by Dr. Watson. In preparing the limb for the operation, the tourniquet was not used, but Esmarch's bloodless apparatus was applied. Dr. Watson used the saw from below upwards, Dr. Dawson reversed this, the advantage being apparent; for, after the disarticulation, the foot being loosened at the medio-tarsal articulation, it can be so bent upwards as to lessen the tension of the dorsal tendons to such a degree, that the saw can be introduced and used with much greater ease. Dr. Dawson, instead of introducing layer after layer of lint, until the tunnel was completely filled up, rolled a piece of lint large enough to fill the opening, and introduced it at once. The result of the operation was most satisfactory. The parts seemed completely solidified, and with a shortened foot, the patient walked without a limp. The advantages of this operation over the dorsal incision, Dr. Dawson thinks are very marked. By it, wounding vessels and tendons, and everything in fact on the dorsum of the foot, are avoided.—*The American Medical Weekly, January* 29, 1876.

The Median Operation for Stone in the Bladder.—Mr. Joseph Hunt gives the history of twenty cases of stone in the bladder removed by the median operation at the Leicester Infirmary. Only one of these cases ended fatally, and then death resulted from pyæmia, though it is true thirteen of the cases were under the twelfth year. Of eighteen cases, the average number of days from the date of the operation, to the time of recovery was thirty-six. In the fourteen cases in which the record was kept of the time at which the urine first came, per urethram, the average was on the fifth day. These cases are interesting, from the fact that the median operation has been almost wholly discarded at the London hospitals, though at the Leicester Infirmary a long and patient trial of the two methods has lead to the adoption of the median in every case. In one of the cases there was secondary hemorrhage after a free incision of the prostate.—*The Lancet*, March 18, 1876.

Kava-Kava, a Remedy for Gonorrhœa.—An infusion of the root of the kava-kava (*Piper methysticum*) has long been a popular remedy for gonorrhœa in the Pacific islands. Three or four scruples, or even more, of the grated root are macerated for five minutes in two pints of water, the whole being frequently shaken up. This water after filtration is given in two doses during the day, before or after meals, and repeated every day until a cure is effected. Twenty minutes after the first dose, a pressing desire to urinate is experienced. The quantity of urine is abundant, and it becomes limpid and as clear almost as water. The pain that was present during the previous micturitions disappears, and a sensation of comfort is experienced in urinating. A cure requires ten or twelve days. The kava, moreover, acts like a bitter tonic. It is pleasant to take, stimulates the appetite, does not derange the digestive functions, and produces neither diarrhœa nor constipation.—*Gazette Médicale de Paris*, April 1.

THE ENGLISH DEBATE UPON THE PATHOLOGY OF SYPHILIS.

We have watched with much interest the progress of the debate upon the pathology of syphilis, which has occupied four sessions of the Pathological Society of London. Considering the exceptional importance of the subject, and also the high position of some of the speakers thereon, we thought it due to our readers to present them with a condensed outline of the leading paper, and of the replies evoked by it. We certainly think that the council of the society showed good judgment in selecting Mr. Jonathan Hutchinson as the person to open the debate, and further, that he has in the main performed his task well. At the outset, however, we must express our disapproval of the statement so emphatically made at the commencement of the paper, in which Mr. Hutchinson says: "I think we may say of dualism that it is dead, and that the now simpler creed which attributes the soft chancre to contagion with inflammatory products produced by syphilis, but not as a rule containing its germs, is the one which obtains general acceptance. We have, then, in syphilis, but one malady and one virus." We think this statement is for various reasons ill-judged. As dualism is not one of the distinct issues of his paper, he should not thus curtly allude to it and dismiss it, as by so doing he opened the way to irrelevant discussion, and at the same time rendered himself liable to mislead those who are not familiar with the minute aspects of the question. Clinically, to-day, the fact that the hard sore always produces syphilis, and that the soft sore does not, but that it is simply local in its operation, is as generally received and as susceptible of overwhelmingly convincing proof, as it was when it was so boldly advocated by Bassereau twenty-odd years ago; and the fact, or rather the statement, that this local or soft sore is related more or less remotely with syphilitic inflammatory processes, while in a measure it modifies the dualistic view in a theoretical way, has no practical effect upon it,—certainly it does not demolish it. Hence we think that the allusion made by Mr. Hutchinson was ill-judged and misleading in its effect, particularly so if his words are carefully weighed; for he says that the soft sore may not, as a rule, contain syphilitic germs; the inference is plain that sometimes then it may, when, of course, syphilis would follow. We judge from the whole tenor of his remarks that he does not really think that this is the case. As is well known, Mr. Hutchinson has been one of the most ardent advocates of the view that syphilis is a specific fever, having definite stages, with periods of incubation, and of the outbreak of the efflorescences or exanthems, followed by sequelæ, which are generally called tertiary lesions. These opinions he here reiterates, and devotes much space to prove that tertiary lesions are not direct effects of the disease, but rather results or sequelæ of it. His argument in support of this opinion, which by the way was severely criticised, is that in the early stages of syphilis the manifestations are general and symmetrical, thus proving, he thinks, that it is then a blood disease; but that after a greater or less lapse of time, they are unsymmetrically developed, which fact goes to prove that they are not any longer manifestations of a blood disease, but on the contrary, as we have said, sequelæ of it. He thinks that the same feature is observed in the course of the exanthemata. Mr. Hutchinson thus expresses himself: "In all probability syphilis ceases to be a blood disease at the date when symmetrical manifestations cease to be usual. This period varies according to the treatment adopted and the idiosyncrasy of the patient." As to the date at which syphilis is no longer contagious, Mr. Hutchinson truly says that negative evidence goes to prove that this is the case in the tertiary period, and adds that the power of hereditary transmission may remain long after this cessation. Practically, this point is of great importance. As instances of the local lesions or sequelæ, the author cites the relapsing affections of the tongue and skin, and thinks that the fact that these are amenable to local treatment is in a measure proof that they are not real manifestations of the disease. He further suggests that perhaps local treatment would also cure the internal gummata, if they were likewise accessible. He does not think that Lancereaux simplifies the question of periods by calling the tertiary stage the period of gummy deposits, as such are sometimes found even in the secondary stage. He admits that these secondary gummata are not dissimilar from those of the later period. This opinion appears very singular, when compared with the statement that tertiary gummata are sequelæ.

He then considers the peculiarities of syphilitic inflammations, and the relation of the various lesions

histologically the one to the other, which he considers very intimate. In the first category he calls attention to the immunity generally possessed by syphilitic growths to suppuration, and at some length speaks of their tendency to produce phagedena and sloughing, as well as in some instances to undergo interstitial absorption. As to syphilis being the cause of phagedena, he expresses himself more strongly than any authority with whom we are familiar, as he says: "So marked is the liability to phagedena in syphilis, and so rare in connection with any other cause, that, with few exceptions, we may count syphilis either directly or indirectly as the parent of all phagedena." Reverting again to that still unsettled question, the periods of syphilis, Mr. Hutchinson very forcibly states that attempts to found a division of the secondary and tertiary stages by a tendency or otherwise to deep ulceration only add confusion to the subject. We think, however, that he fails to make clear his position as to the distinctly marked differences in these periods. His chief reliance is upon the symmetry of the secondary stage, and the absence thereof in the tertiary. He carries this idea to the extent of saying that if rupia is symmetrically developed it is a secondary manifestation, while if not symmetrical it is tertiary, there being no peculiarity of the lesion to settle the question. Though in some instances this may be true, there are so many exceptions to the statement that it should not be unreservedly received. In speaking of symmetry and asymmetry of eruptions, Mr. H. makes a remark which is certainly at variance with his position, that it is a *question* of *abundance* rather than of character, which really means that in the secondary stage the infiltrations are copious, and scanty in the tertiary. Finally, as regards differences between secondary and tertiary lesions, he states that the former undergo spontaneous resolution, while as a rule the latter do not. Foreseeing that it may be urged that in the secondary period the more superficial tissues are the ones generally involved, and then only in a superficial way; and that in the tertiary stage deep ulceration takes place and deep tissues are involved—says he can only admit, with great limitation, these assertions, as the ulcerative processes are often severe in the secondary stage; and that we do not know definitely that the viscera are not involved in the secondary period. This leads him to offer a suggestion of much practical value, namely, the necessity for study of the effect of syphilis in its early or secondary stage upon the viscera. He clearly shows, by numerous examples, that in this stage other tissues than the more superficial ones are affected. This portion of the paper is both interesting and suggestive. Further, he advances the hypothesis that tertiary lesions may really be only the result of secondary ones, they developing themselves in tissues upon which secondary lesions have stamped a morbid impress. This suggestion is worthy of attention, though abundant evidence can be cited against it. It is, as Mr. H. says, different from the theory advanced by Virchow, that tertiary lesions and relapses are due to the syphilitic poison stored away in lymphatic glands, and from them bursting forth and thus involving blood and tissues. Passing, then, to the consideration of hereditary syphilis, he sketches in a general way its course, and alludes to its more prominent features. He thinks that in this form we do not, as a rule, meet the well-marked tertiary lesions of the acquired variety, such as cellular tissue gummata and lesions of the muscles and tongue. In children we have less frequently nervous phenomena than in adults; and in them is to be observed, as a rule, a more marked limitation of the disease; so that, although a child may suffer for years with lesions of inherited syphilis, its future life will usually be free from syphilitic manifestations. Mr. Hutchinson is very explicit in his statements as to the relation of syphilis and scrofula, and thinks that the manifestations of both conditions are markedly distinct the one from the other, and that they possess no pathological relation with one another. We must express our surprise that Mr. H. does not acknowledge that syphilis may act as a predisposing cause to the production of scrofula. To our surprise he, we think unnecessarily, considers the relations between lupus and syphilis, but very properly concludes that none exist. The paper ends with a grateful acknowledgment of the labors of the various living observers upon syphilis. In our next we shall give a synopsis of the views of the gentlemen which were called forth by the opening of Mr. Hutchinson..

HOMŒOPATHY IN THE UNIVERSITY OF MICHIGAN.

The State Society of Michigan, at a recent meeting, and after an exciting debate, adopted a resolution condemning the course of the faculty in regard to the homœopathic question. An amendment was offered to the Constitution, which, under the rules, was laid over until the next annual meeting, refusing fellowship to any graduate of the University while the present arrangement continues. Amid the excitement attending those proceedings, the Society adjourned, with much of its important business unfinished.

Every one interested in the proper solution of the matters in dispute will be sorry that such radical measures have been adopted, and that such a spirit of partisan zeal has controlled the deliberations of a strictly scientific body. Nothing can show more clearly that the Michigan State Society is absurdly intolerant of homœopathy than the recent action alluded to. The extreme attitude assumed is of itself a confession of weakness, an attempt to force conviction by arbitrary means, rather than a manly and fearless endeavor to meet the questions at issue, and discuss them with the calmness of men who desire to know

the truth, the whole truth, and nothing but the truth. If we are ever going to expose the error of homœopathy we must give it plenty of light and air. We have dignified it with martyrdom long enough. If we are not afraid of it we can afford to offer it every opportunity for proving its superiority. The faculty of the University, in view of the issue at stake, should be upheld rather than condemned. The idea of yielding up the school to the homœopaths is preposterous. The liberality of conceding the homœopaths even what they have, will afford them the surer means of working out their own destruction.

Homœopathy is a rank weed that has always flourished in the low and damp recesses of hypocrisy, and we have fostered this tendency by shadowing it with our prejudices. The longer we do this, the stronger will be its growth, and the more effectually will it entwine with the ignorance of the masses. If, on the contrary, we give it the impartial sunlight of truth, it must sooner or later shrivel into the infinitesimal proportions of its own doctrines. We, at least, are willing to give it such a chance. It never can be done, however, by any such resolutions as were passed by the Michigan State Society.

THE SHORT TERM SYSTEM.

Dr. Gaillard calls our attention, in a recent number of his journal, to what he terms "surprising blunders" on our part, in stigmatizing the short term system of medical study in Louisville as "corruption in high places," etc., whereby "the readers of the 'Record' have been induced to believe that the terrible conditions indicated really exist."—We are not sorry that we have conveyed such an impression, as we intended to do so. We believe that such a state of things as graduating a student in nine months does exist in Louisville; and, in view of our opinion, as to what a medical education should be, we are forced to repeat that the system is a "monstrous evil" and should be checked at once. We do not care what College endorses the practice, or what journal advocates it, we still say it is wrong; that it is an evidence of "corruption in high places," and that it is an abuse of the diploma-granting privilege. Dr. Gaillard, in his defence of this cramming system, asks the question: "Has the time not come when qualifications should be the test for graduation, and not time?" One is such a necessary condition of the other that they cannot be separated. It is, to our way of thinking, such an impossible thing for the most brilliant intellect under the best possible training, to digest even the rudiments of medical science within nine months, that we are quite willing to give the element of time between meals, very serious consideration.

The next meeting of the American Medical Association will be held in Philadelphia, on Tuesday, May 6th, 1876, at 11 A.M.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, April 26, 1876.

Dr. Chas. K. Briddon, President, in the Chair.

FISH-BONE REMOVED FROM PHARYNX BY PARACHUTE PROBANG.

Dr. Lewis A. Sayre presented several specimens of exsection for morbus coxarius, previous to which, however, he exhibited the shoulder of a codfish which had been extracted from the pharynx of a lady, by his son, Dr. Charles Sayre, by means of the œsophageal parachute probang. The patient was suffering intensely, and was in the agony of impending suffocation, when the prompt introduction of the instrument and the extraction of the foreign body gave her instant relief.

EIGHT ADDITIONAL CASES OF EXSECTION FOR MORBUS COXARIUS, MAKING SIXTY-ONE IN ALL.

Dr. Sayre, in presenting these cases, stated that he did so for the purpose of placing them upon record in their order. The first specimen, consisting of the head and neck of femur, with portions of the acetabulum, was numbered 54, and had the following history:

Case 54.—Charles Braman, aged 4. Born of healthy parents. Was first noticed to be lame in March, 1873. Knows of no fall or other injury. Child very greatly emaciated; very anæmic; profuse discharge from three openings above Poupart's ligament, and another upon outer part of thigh.

Exsected March 28, 1875.—Head and neck absorbed; upper end of shaft of femur covered with a thick involucrum. Femur black and necrosed, and sawed off just below trochanter minor; the disease having progressed farther down upon the inner side of the femur, another section was made a quarter of an inch lower. A loose piece of bone, about the size of an almond, was picked out of the acetabulum, giving exit to a large quantity of pus of a fecal odor, which had been imprisoned behind the ilium, and had caused the sinuses above Poupart's ligament.

Dressed in usual way and placed in wire cuirass. The dressings were not touched for two days, when the oakum was removed from around the hip, the wounds cleansed, and the dressings reapplied.

June 13, 1875.—Child has been very comfortable since the operation. The sinuses above Poupart's ligament have almost closed. Removed from wire cuirass, and long extension splint with abducting screw applied.

January 1, 1876.—Can stand on the leg when splint is removed, and walk with it on. Considerable motion at joint. Slight discharge from sinus on posterior part of ilium. Condition seen in photograph taken in December, 1875.

Case 55.—John F. Drum, 5 years old. Healthy parents. Stout boy until 30 months ago, when he fell and struck his knee upon the stones in the street. Has been blistered repeatedly. Very much reduced. Limb in position of third stage. Large abscess over trochanter major, which was opened by a free incision, discharging a large quantity of pus, and exposing a rough and necrosed trochanter.

Exsected April 31, 1875.—Head partly absorbed, and a piece of it lying loose in the acetabulum. Neck and part of shaft of femur absorbed. Aceta-

bulum perforated. Femur sawed below trochanter minor. Two pieces of bone removed from acetabulum. Child was placed in cuirass and removed at once to Jersey City, by Dr L. J. Gordon, under whose care he has been ever since.

February 2, 1876.—Child was seen to-day for the second time since the operation. Sinuses entirely closed. Has considerable motion at hip. Can stand upon leg without pain when the splint is removed.

Case 56.—Bridget D. Smith, aged six. Born of healthy parents. Several brothers and sisters, all remarkably healthy. Has been lame since February, 1872. Knows of no injury, although she has had repeated falls, having been a very active child. Has been blistered repeatedly without relief. Child is very much reduced, and very anæmic. Leg shortened, adducted, and fixed. Two sinuses on anterior part of thigh leading to dead bone and discharging freely.

Exsected March 31, 1875, *at Bellevue Hospital Medical College.*—Head absorbed, also greater part of neck. Femur sawed just below trochanter minor. A second section was made about one-quarter inch lower down. Several pieces of bone removed from acetabulum which was perforated by a hole about the size of a small penny. Sinuses slit up, scraped, and filled with Peruvian balsam; wound dressed in usual way, and child placed in cuirass, and taken home to Forsyth street.

Child continued to improve, had no constitutional disturbance, and was removed from cuirass and placed upon long splint. Condition is seen in photograph taken August, 1875.

Case 57.—Ellen Sullivan, aged five years. No history of the cause of the disease or its duration could be obtained in this case, as the child's father was dead and her mother in the lunatic asylum. Her limb was in the position of the third stage of morbus coxarius and partially anchylosed. Several sinuses on outer and posterior surface of thigh led to dead bone. Child was pale and very thin.

Exsected September 22, 1875, *at Bellevue Hospital.*—Head nearly absorbed, a small piece of it lying loose in the acetabulum. Femur sawed off just above trochanter minor. Acetabulum perforated, and plugged by remains of head. Large quantity of pus retained behind the ilium, which was evacuated when loose; piece of head was removed. Sinuses on thigh scraped and filled with Peruvian balsam. Child dressed in wire cuirass.

November 18.—Has been quite comfortable since operation. Has gained considerable flesh, and has quite rosy cheeks. Removed from cuirass and applied long splint with abducting and everting screws.

February 2.—Child has been walking around the ward since the splint was applied. Sinuses nearly closed, discharges very much diminished. Short hip splint applied in place of long one.

Case 58.—Rosa Mullins, aged three years. Parents both healthy. Two other children both very healthy. Said to have had a fall, but no positive information could be obtained. Disease first noticed after a severe illness in summer of 1874. An abscess on posterior part of thigh was opened in June, 1875, and still continues to discharge freely.

Child very small, white, and emaciated. Abdomen distended. Limb adducted, shortened, and fixed.

Exsected September 29, 1875.—Head, neck, and part of great trochanter entirely absorbed; acetabulum perforated. Three small pieces of bone picked out of acetabulum. Wound stitched and dressed with oakum and Peruvian balsam. Child placed in wire cuirass.

December 13 1875.—Short hip-splint applied.

Case 59.—Mary Mahony, aged seven. Two and a half years ago jumped from a high stoop, and immediately afterwards complained of pain in hip. This gradually passed off. Three months afterwards had sharp pain at night. Was then seen by a physician, who diagnosticated hip disease in second stage, and applied short splint. This was worn for three months with great comfort; at the end of this time child was taken with scarlet fever, and the splint was removed and never reapplied.

Child gradually grew worse, and was admitted to Bellevue Hospital March 29, 1875, in the following condition:

Limb adducted, flexed, and fixed. Several sinuses around right hip. Considerably emaciated and anæmic. Probe touches dead bone. Exsected December 15, 1875. Head partly absorbed. Femur sawn just below trochanter minor; a second section was made nearly half an inch lower down, as the bone was farther diseased.

February 2, 1876.—Child removed from cuirass and placed in long splints.

Case 60.—Charles Pixlee, aged nine. Patient's mother died of phthisis. Patient has never been a strong healthy boy. Three and a half years before admission to Bellevue Hospital his father noticed that he walked lame. No cause known. Was sent to boarding-school, where he was obliged to go up and down several flights of stairs during the day. Grew worse, and was put to bed and extension by weight and pulley applied. Two months after short splint applied, worn with comfort for several months, when the physician in charge was taken sick. The splint was then removed, and the child gradually grew worse.

Admitted to Bellevue Hospital in the following condition: "Is a very delicate child and reduced almost to a skeleton. Suffers intense pain when he is moved or touched. Right leg flexed at hip and knee joints. Sinus in upper and anterior part of thigh, bed-sore over sacrum. Abscess over right anterior superior spinous process. Albumen in considerable quantities in the urine. Symptoms of waxy liver.

Exsected February 2, 1876.—Head partly absorbed. Acetabulum perforated, and neck of femur caught in the opening, rendering luxation impossible. Femur sawed below trochanter minor. Some hemorrhage from artery in thickened involucrum, controlled by oakum compress.

Child placed in cuirass, but removed at the end of a few days, and placed on air-bed, with right-angled splint upon well side.

Died, April 19, 1876, from exhaustion. Liver, spleen, and both kidneys markedly waxy, responding to iodine test. Liver very much enlarged, weight three and three-quarter pounds. Heart and lungs normal.

Case 61.—Charles Smith, aged eight. Caused by frequent falls, as the boy was continually tripping. Has always been a stout, healthy boy.

Five fistulous openings, one of them in the groin. Very much run down from want of proper food and good air.

Exsected April 5, 1876.—Head and neck absorbed, and end of femur thrust through the acetabulum. Bone sawed through and removed by forceps. Acetabulum extensively necrosed. Several pieces of bone removed from acetabulum. Larger abscess between ilium and internal periosteum.

The specimens belonging to the different cases were exhibited to the Society. Dr. Sayre, in connection with these cases, took occasion to refer to the following statement from a recent English work entitled: "Diseases of the Hip, Knee, and Joints, and their

Treatment by a New and Efficient Method," by Hugh Owen Thomas. On page 6, Mr. Thomas says: "Since the visit of Dr. Sayre to England, and the exposition of his method to the London surgeons, I have seen several instances in which his apparatus was skilfully applied, and from personal knowledge I am satisfied that in not one of these cases was the disease benefited or even arrested. The best commentary upon this method is the remarkable frequency with which its principal advocate has had to perform excision."

DR. SAYRE, in reply to this assertion, stated that he never had occasion to exsect a hip joint in any case that came to him in the first and second stages of the disease, but had seen hundreds of the latter recover without deformity, and with perfect motion. The cases in which exsections had been performed were almost *in articulo mortis* at the time of the operation.

THE EFFECT OF OPERATION ON ARRESTING WAXY DEGENERATION.

DR. MASON asked how many of his (Sayre's) cases died within the first year after the operation.

DR. SAYRE could not say positively in the absence of his records, but believed the number to be eight, all but three of which were complicated.

DR. MASON was certain that in the majority of the cases amyloid degeneration existed at the time of the operation, and it was a matter of some importance to ascertain what effect such an operation might have in arresting the waxy change in the internal organs by the removal of the exciting cause. In this connection he referred to a case which was operated upon by Dr. Sayre two or three years ago, in which there was extensive waxy degeneration of liver and kidneys, and which recovered.

DR. SAYRE stated that the particular case alluded to was reported to the Society in 1873 (*vide* MEDICAL RECORD, vol. viii., p. 460). The patient was a male, 11 years of age, who was dying of waxy degeneration, the result of suppurative hip disease, and the operation was performed more on account of the boy's constant importunity than for any hope of benefiting. Strange to say, however, after the operation the patient began to improve in all his symptoms, and enjoyed two years and four months of perfect health, the albumen and casts finally disappearing. His death was the result of an attack of acute nephritis, the result of an exposure to cold. No autopsy was attainable.

DR. GEDNEY remarked that, as a matter of clinical experience, he had often noticed a direct relation between the quantity of a chronic suppurative discharge and the size of the internal organs which were the subjects of fatty degeneration. For instance, when there was an interruption in the discharge, there was a corresponding diminution in the size of the liver and in the quantity of albumen in the urine, and *vice versa*.

DR. KNAPP stated that in the present state of our knowledge it was impossible to say what would be the duration of amyloid degeneration. In this connection he referred to a case of amyloid degeneration of the choroid presented to the Society in June, 1873, and which he had seen only a few days ago in apparently perfect health. In that case the degeneration was confined to the arteries of the choroid (MED. REC. vol. viii., p. 547).

EPULIS OF LOWER JAW.

DR. ROBINSON presented a specimen of the above with the following history:—J. P., German woman, aged 44 years; does housework; eighteen years in the United States; has had eight children—five living all healthy; she has always been perfectly well; came under my care one month since. About three years ago noticed a tumefaction of the gums at the left of the median line of the lower jaw; the swelling increased very slowly until beginning of last pregnancy—two and one-half years ago—when it took on a more rapid growth. During her period of pregnancy it increased rapidly and reached its present size—that of a cherry. Since birth of last child, nine months ago, it has not augmented. It has rarely been painful, and has more particularly caused her mechanical trouble by its presence interfering somewhat with the closing of her jaws, and consequently with mastication. In wet weather she has remarked that the tumor becomes somewhat sensitive.

The tumor presented the aspect of a small globular mass about the size of a cherry. It is tolerably smooth, of a rosy color, very consistent, and not at all pulsating to the touch. It adheres by a broad base or pedicle, to the periosteum of the alveolus of the left lateral incisor tooth of the lower jaw. It is not adherent, apparently, to the bony structure of the jaw, and is somewhat movable upon its base. When moved from side to side there is a little bleeding about its base, seemingly brought on by an ulcerative process, caused by the neighboring teeth, which it has pushed aside by its own pressure in growing. It is difficult to say positively whether the incisor tooth at the seat of the growth is incorporated with it. The patient thinks so, as she does not remember having lost a tooth at this region. The teeth of the patient are generally defective, and she has already lost several.

About three weeks ago he excised this tumor. At first I attempted to dissect it away from the gums by means of the bistoury. In this I failed, as it was of too hard consistence. I therefore used the bone forceps, cutting down on either side of it, until I had penetrated nearly to the base of the alveolus, and then by means of a gouge-shaped dental forceps tearing away tumor with a small portion of bone. By way of precaution against return of growth, I was compelled to extract one incisor tooth, and after the operation was terminated and the bleeding arrested I cauterized the base with nitrate of silver.

Upon section the tumor presented a tolerably homogeneous structure to the naked eye, and was apparently largely made up of fibrous tissue. There was no tooth enclosed in its tissue. The microscope shows it to be a so-called fibro-plastic tumor, or spindle-celled sarcoma.

One of the points of interest in the case had reference to the liability of return. In the instance in question the glands in the neighborhood, as Dr. R. believed was usual in cases of pure sarcomatous tumors, were not involved. He thought from a chemical point of view it was of importance to note the fact of the freedom of glandular infiltration, as bearing upon non-malignancy.

DR. BRIDDON had seen two or three similar cases with no glandular complication. Dr. MASON had seen but one growth of the kind return, and that was in the course of four months from the time of the operation. One case he had operated on ten years ago, without any return of the disease. Dr CROSBY referred to one case in his practice, in which the tumor was simply removed from the periosteum and in which the disease returned within a month. At the next operation a portion of the bone was removed with the tumor, since which time, three years ago, there had been no return.

THE CHEMUNG COUNTY MEDICAL SOCIETY, N. Y.

Fortieth Anniversary.

RECOVERY FROM TRAUMATIC TETANUS—TYPHOID FEVER AND HEMORRHAGE FROM MAMMARY GLAND—INVERSION OF UTERUS—TANSY POISONING—CONGENITAL RECTO-VAGINAL FISTULA—THE HYPODERMIC SYRINGE AS AN ASPIRATOR IN STRANGULATED HERNIA—OPIUM POISONING—THE CARE OF THE INSANE—COMPLETE RUPTURE OF URETHRA.

This Society held its Fortieth Anniversary in the city of Elmira, N. Y., on the 21st of March, 1876. S. W. Bailey, M.D., President, in the Chair. The following is a synopsis of some of the papers read:

TRAUMATIC TETANUS—RECOVERY.

Reported by P. H. Flood, M.D., of Elmira, L. Y., lad of nineteen years; railroad injury, Dec. 27th, 1875, calling for amputation of the great toe, and the two adjoining toes, of the left foot. A physician was called, who performed the operation, apparently with the object of saving as much of the toes as possible, as there was very little integumentary covering for the end of the bones. From this time till the 15th of January he was about the house on crutches, apparently very comfortable; appetite good. On the 19th (twenty-three days from the date of the injury), after four days of premonitory symptoms, he was attacked with *tetanic spasms*, the muscles becoming rigid, and the whole body stiff and straight. The muscles of the neck and jaw were chiefly affected, producing trismus, or lock-jaw. Seventy-five drops of laudanum were given, and morphine hypodermically for two days, with but little effect. Change of physicians then took place. At this time the patient's condition was calculated to excite feelings of the deepest compassion. He was lying upon his back, his head drawn backward and fixed by rigid contraction of the muscles of the neck, the jaws firmly set, the skin of the forehead wrinkled, the eyes rigidly fixed, and sunken in their sockets, the pupils being dilated. The angles of the mouth were drawn down, exposing the teeth, firmly clenched, and an occasional twitching of the mimic muscles, and oozing of blood from the mouth, added to the shocking appearance. The whole body was rigid and frequently convulsed, the patient screaming with remittent pains, and drenched with perspiration. Pulse weak and small; 120 per minute. The paroxysms were of variable duration, sometimes quite brief, and at other times continuing from a quarter to half an hour, being easily provoked by the shutting of a door, the noise of a stove, barking of a dog, etc.

Upon examination of the wounds of the foot at this time, they were found to be dressed with simple cerate, that of the great toe being nearly healed. The two lesser toes were enlarged, swollen, covered with fungous growths, and discharging freely, the odor being extremely offensive.

A soft poultice was substituted for the cerate. Absolute quietude and freedom from all exciting causes, both physical and mental. Fifteen drops of the tincture of aconite leaves injected hypodermically. This seemed slightly to relax the tetanic spasms. On the evening of the same day (Jan. 23) the injection, fifteen drops of the tincture of aconite, was repeated.

Jan. 24th, 9 A.M.—Found patient much the same as previous evening. Spasms continue, but with less severity. Hypodermic injection of Magendie's solution of morphine, thirty drops, with tinct. of aconite leaves, thirty drops. One hour after this administration the patient experienced decided relief; spasms not so severe or frequent. 9 o'clock, P. M.—Patient has remained about the same during the day. About half an hour ago spasms became more severe, with increased rigidity and pains. Repeated the medicine, same as in the morning; morphine 30 drops, tinct. aconite 30 drops. Half an hour after this he began to improve. Pulse, 120, irregular, weak and feeble; profuse perspiration; could open his mouth; drank some whey, beef tea and cream.

Jan. 25th, 9 o'clock A. M.—Patient comparatively comfortable during the night; sleepy, but did not sleep; effects of the medicine commencing to disappear; spasms continue same as day previous. Repeated the injection, which produced almost immediate relief; could extend his tongue; found it bitten and swelled; continue beef-tea and cream. nine o'clock P. M., patient quite comfortable; spasms at longer intervals, and less intense. Continue hypodermic injection as usual; move the bowels with enema; diet the same.

Jan. 26th, 9 A.M.—Patient better; had occasional spasms during the night, but towards morning ceased entirely. Severe pain in hips and back; very sore, stiff and rigid. Continue the hypodermic injection as usual. 9 o'clock P. M.—Patient comfortable during the day; took nourishment, beef-tea and cream.

Jan. 27th, 9 A. M.—Patient comfortable; slept fifteen minutes during the night. 28th, comfortable, but no sleep. 29th, much the same, slept half an hour. 30th, Gave an enema, profuse perspiration; pulse feeble and frequent. 31st, slept an hour at a time. Feb. 1st.—Patient appears better this morning; sleept good during the night; still complains of pain and soreness in back and hips; moved limbs for first time in fourteen days. Feb. 2d—Slept good; turns over in bed. Feb. 3d.—Still improving; slept soundly.

Feb. 4th.—Appetite increasing; soreness and stiffness disappearing, unable to bend forward, even with assistance; pupils still dilated; can partially open the mouth; pulse stronger and not so frequent. The medicine has been continued every twelve hours in the same dose (morphine 30 drops, tinct. aconite 30 drops). The patient was, at length, fully restored to health, under this treatment.

TYPHOID FEVER ATTENDED WITH HEMORRHAGE FROM THE MAMMARY GLAND.

Case reported by Dr. Wm. H. Davis, of Horseheads. This case was peculiar, with respect to the source of the hemorrage. Death was the result.

Dr. Louis Velder, of Elmira, read a paper entitled: "A Case of Puerperal Convulsions, complicated with acute Bronchial Catarrh, followed by Œdema of the Lungs. Fatal Termination."

INVERSION OF UTERUS.

Dr. H. S. Chubbuck, of Elmira, reported a case of inversion of the uterus. Mrs. J. K., aged 27 years, confined with first child Dec. 3, 1874. Duration of labor twelve hours; very severe for six hours; after short delay placenta was expelled with slight pains. There was considerable flowing for the first few days after delivery, but nothing wrong with the uterus. On the sixth day, contrary to orders, she was placed in a large chair and drawn into an adjoining room. While in the chair she felt something give way internally, and complete syncope occurred. She was placed in bed, and Dr. Chubbuck was soon with her. She was then very faint, and appeared bloodless; pulse 140 and feeble. The uterus was then discovered to be completely in-

verted. Having obtained chloroform, and secured the presence of Dr. Wey as counsel, the anæsthetic was administered, and efforts were commenced for the purpose of reducing the organ. The reporter says: "I passed my fingers up to the neck of the inverted womb, clasped the organ with my hand gently but firmly, making steady pressure, and at the same time passing my hand upward; and, as the womb gradually receded, I moved my hand downward, towards the fundus, and grasped anew, gently but firmly passing the uterus upward until the fundus was reached, then pressed my thumb and fingers at the inverted fundus, and carried it to its normal position, with my hand inside of the uterus, holding it there until the contractions were sufficient to warrant its withdrawal." Two days afterwards an examination was made and the organ was in its normal state. Phlegmasia dolens of both limbs afterward; but under appropriate treatment, the patient convalesced, and finally regained her perfect health.

CASES OF TANSY POISONING.

Reported by Dr. Henry Flood, of Elmira. Mrs. S., aged 25, mother of one child, being pregnant again, and desiring to produce abortion, she procured one ounce of the oil of tansy, and swallowed one teaspoonful of it, and retired for the night. She experienced a burning sensation in the stomach, and was soon in convulsions of a severe and dangerous character. The patient being unable to swallow, the doctor administered a mustard emetic by means of a Davidson syringe. Vomiting followed; the matters ejected having a strong odor of tansy. The patient not only recovered, but she escaped abortion, and two months afterwards was progressing in pregnancy.

Mrs. D., in the second month of pregnancy, took largely of a strong decoction of tansy, and experienced symptoms similar to the foregoing. An emetic of mustard had the desired effect in this case also.

IMPERFORATE ANUS, WITH CONGENITAL RECTO-VAGINAL FISTULA.

Reported by Dr. J. K. Stanchfield, of Elmira. The doctor prefaced his description of this infantile malformation with the statement that the mother had—resulting from her first delivery—an extensive laceration of the perineum and recto vaginal septum, which had been remedied by a surgical operation. Resulting from her second delivery there was a slight rupture which did not require a second operation. During this, her third pregnancy, the mother was continually possessed with an apprehension that there would be some deformity, and the thought of the horrible recto-vaginal laceration was often pictured in her mind.

Upon examination, after birth, this third offspring was found to be without an anus; the skin retaining its natural color over the whole space between the parts of generation and the coccyx. Twenty-four hours after birth there was a dark-colored discharge noticed upon the diaper. Further examination revealed a small opening from the posterior wall of the vagina directly into the rectum. Through this small opening the contents of the bowels found a way into the vagina. At the time of reporting, no surgical operation had been performed to remedy the malformation.

The doctor closed his paper by saying: "In this case, it seems as though the maternal imagination must have had some influence in causing this defect in the offspring.

MERCURIAL FUMIGATION IN SPECIFIC DISEASES.

Was the subject of a paper presented by Dr. F. B. Abbott, of Elmira.

STRANGULATED INGUINAL HERNIA.

Case reported by Dr. Albert H. Flood. Mr. B., aged 35 years. After all the ordinary methods of taxis have completely failed, the doctor drew the barrel of a common hypodermic syringe four times full of amber-colored liquid from the tumor, reducing its size at least one-half, and then the loop of intestine was very easily returned into the cavity of the abdomen.

CHASSAGNY'S OBSTETRIC FORCEPS.

Dr. Charles L. Squire, of Elmira, gave an elaborate description of this forceps, explaining its principle of construction and philosophy of action.

Some of its special advantages were summed up as follows:—

1. Reduction of the transverse diameters of the head, *without compression of the brain.*

2. Traction in absolute obedience to the natural direction and movements of the head.

3. Sustained traction.

The new instrument has been used in the city of Elmira during the past year, in two cases, by Drs. H. S. Chubbuck and T. H. Squire, and these physicians were much pleased with its operation.

OPIUM POISONING TREATED BY HYPODERMIC INJECTIONS OF TINCTURE OF BELLADONNA, COFFEE, AND WHISKEY.

Case reported by Dr. John M. Flood, of Elmira. This patient was so profoundly narcotized that, for a time, the respirations were but one per minute, and the pulse forty-two per minute. For the space of four hours the hypodermic syringe was constantly used injecting whiskey and coffee; and several times during the same period tincture of belladonna was injected in doses varying from ten to thirty drops. Success at length rewarded these measures. The reporter says that, probably, more than two hundred injections of whiskey and coffee were administered in the space of four hours.

DIRECT COMMUNICATION BETWEEN STOMACH AND COLON.

A case of the above was reported by Dr. E. Gere, of Chemung.

Mrs. G. W. B., aged about fifty years. Extreme emaciation; left leg œdematous; a fistulous opening at the umbilicus, and a small quantity of fluid oozing therefrom. On opening the abdominal cavity there was found a funnel-shaped formation, consisting of cellular tissue, adherent to the wall of the abdomen, its upper or large end surrounding the colon and duodenum, where they cross each other; the lower or small end communicating with the umbilicus externally, thereby preventing any pus or extraneous substance from escaping into the abdominal cavity. On removing this special canal, the colon was found to be adherent to the duodenum at the point of their crossing, and an opening about an inch in diameter communicated between the two, so that food, or chyme, instead of traversing the small intestines, passed directly from the duodenum into the colon. The gut above the opening was healthy and about the natural size, but below it was contracted or thickened, obliterating very nearly the passage for four or six inches. There was no cancerous appearance about the opening; its edges were well adherent, so that no part of the contents of the stomach could escape into the cavity of the abdomen. The stomach and liver were healthy. During life, the symptoms were those of cancer of the stomach.

CARE OF THE PAUPER INSANE.

Dr. William C. Wey, of Elmira, read a paper re-

citing the history of the pauper insane in the State of New York. The care of the State over the insane, the deaf and dumb, the blind, the idiot, and to some extent of the inebriate, was briefly considered. The writer noticed at some length the intricate question of poor-house care and relief, in its effects upon individuals and upon society at large, and sketched the condition of the Chemung County Poor-house, in respect to the young, the middle-aged, and the aged inmates, whom destitution and disease had brought within the sphere of its custodial authority. He denounced the poor-house system, as it fell under his observation, as inhumane, disorderly, and degrading. Idiots, imbeciles, epileptics, paralytics, men and women long insane and demented, were grouped indiscriminately with paupers, old and young, under nearly the same features of treatment. The more violent insane, secured in filthy cells, and separated from the common paupers by a simple arrangement of upright wooden bars, might be said to share the constant society of the latter class, and be subject to their taunts and derision. No attempt was made towards classification or distinction, because of age, condition, or disease. A helpless lunatic lay naked in a rude bunk, filled with hay, and covered with an old and worn blanket. He had been in the poor-house upwards of thirty years, attended by *fellow-paupers*, in the condition mentioned, through successive administrations of superintendents. His companion in the dark and offensive cell, which for so long a time had been his place of incarceration, was a deformed idiot, nineteen or twenty years old. The receptacle which contained these poor creatures opened by a barred partition, from floor to ceiling, into a common sitting-room, which was occupied each day chiefly by old and helpless men, with a sprinkling of younger imbeciles and epileptics. A middle-aged and tractable insane woman proved so useful to the officers of the establishment, that she had been for a long time employed in doing the washing for the house, composed of more than fifty persons. Disregarding the provisions of the law, which gives to county superintendents of poor a period of ten days in which to forward the indigent insane to the Utica or the Willard asylums, according to the recent or long-continued nature of the affection, it was found that a case of the first description, regularly committed by the County Judge to the custody of the superintendent, for removal, *six months before*, still remained in the poor-house. Delay in sending the insane to their destination, particularly in chronic cases, is a common characteristic of poor-house management. The action of the Board of Supervisors in Chemung county, in permitting such gross violation of law and propriety in the care and treatment of the poor and the insane, was sharply criticised.

A CASE OF CYANOSIS, CAUSED BY CONTRACTION OF THE ORIFICE OF THE PULMONARY ARTERY,

was reported by Dr. William Woodward, of Big Flatts.

COMPLETE RUPTURE OF THE URETHRA.

Dr. T. H. Squire, of Elmira, reported the case as follows:

D. E., healthy farmer, aged 30 years. Saw him in consultation with Dr. Hadden, of Pine Grove, Schuyler County, N. Y., on the 12th of January, 1876. Nine days before, from the upper floor of his barn, he had fallen astride a board partition between two horses. The main violence was received at the upper and inner part of the right thigh, and in the perineal region. Retention followed. A catheter could not be used. The aspiration was successfully used for nine days. At the time of my visit, a large, sloughing, ill-conditioned ulcer revealed itself at the upper and inner aspect of the right thigh, and a small round opening existed in the perineum, to the right of the median line, from which urine had escaped for the last thirty-six hours. Tried faithfully to introduce a catheter, but failed; the beak did not pass beyond the membranous portion of the canal. Performed external perineal urethrotomy. Found the urethra entirely divided, transversely, near the bulb. The precise locality of the distal orifice of the ruptured canal was the object of search for nearly or quite half an hour. At length it was found, and a No. 10 gum-elastic catheter tied in the bladder. When all was thus secure, it could be seen that the fractured extremities of the broken urethra were full one inch apart, the naked and uncovered catheter extending from one to the other.

From that time all his symptoms began to mend. The instrument was kept in the canal continuously, or only withdrawn once in a week or two, and a new one immediately put in its place. Free outlets were kept up for all purulent discharges. The dead tissues sloughed away. Granulation slowly progressed, and, after two months and more, the parts were nearly healed. In closing his paper, the doctor said: "By the continued use of a catheter No 10, till the new tissue between the two portions of the urethra is fairly consolidated, a valuable life will be saved, and a most troublesome organic stricture prevented."

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from May 7th to May 13th, 1876.

WEBSTER, W., Surgeon. At expiration of his sick leave assigned to duty as post surgeon at Fort Warren, Massachusetts. S. O. 85, Mil. Div. of the Atlantic, May 9, 1876.

STERNBERG, GEO. M., Surgeon. To report to the Commanding General Dept. of the Columbia, for assignment to duty. S O. 92, A. G. O., May 11, 1876.

KNICKERBOCKER, B., Asst. Surgeon. Ordered before Army Medical Board, New York City, for examination for promotion, and upon its completion to report by letter to the Surgeon-General. S. O. 88, A. G. O., May 5, 1876.

HAPPERSETT, J. C. G., Asst. Surgeon. Granted leave of absence for three months. S. O. 90, A. G. O., May 8, 1876

WILLIAMS, J. W., Asst. Surgeon. Assigned to duty as Chief Medical Officer of Expedition now being organized at Fort Abraham Lincoln, Dak. T. S. O. 63, Dept. of Dakota, May 8, 1876.

BREWER, J. W., Asst. Surgeon. To accompany recruits from New York City to Dept. of the Platte, and upon arrival there report to the Dept. Commander for assignment to duty. S. O. 90, C. S., A. G. O.

MEACHAM, F., Asst. Surgeon. Assigned to duty at Fort Brown, Texas. S. O. 77, Dept. Texas, May 2.

KIMBALL, J. P., Asst. Surgeon. Assigned to duty as post surgeon at Fort Brady, Mich. S. O. 83, Mil. Div. of the Atlantic, May 6, 1876.

MATTHEWS, W., Asst. Surgeon Assigned to duty at Camp Independence, Cal. S. O. 40, Dept. of California, April 20, 1876.

SHANNON, W. C., Asst. Surgeon. Assigned to temporary duty at Fort Clark, Texas. S. O. 78, Dept. of Texas, May 3, 1876.

Medical Items and News.

CONTAGIOUS DISEASES.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending May 13, 1876.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.

May 13th.....	1	6	72	3	46	82	35

COLOR BLINDNESS IN SAILORS AND RAILROAD EMPLOYEES.—Not long since a serious railroad accident occurred just outside the limits of the city, owing, as it appeared, to the engineer confusing the colors of the lights on a train in front of him. Dr. Favre, of Marseilles, calls attention to the fact that while in reference to railway employees the recognition of the red signal is almost the only absolutely essential point, with regard to sailors the green is just as indispensable as the red. At recent examinations of 1050 candidates for employment on railways he has detected as many as 98 color-blind, who were deceived as regards one or more colors, this occurring as regarded violet 78 times, blue 50, green 54, yellow 14, and red 10. Of the 98, 29 only hesitated, and 8 corrected their errors, leaving, therefore, 61 color-blind. Ultimately only 11 had to be absolutely excluded; but if these men had to be examined for sea or coast service, all those who could not distinguish green ought to have been excluded.—*Phila. Med. & Surg. Reporter.*

DEATH OF DR. F. W. ROOT OF HAMILTON, MADISON CO., N. Y.—Dr. Root died on the 8th inst of typho-malarial fever. For more than a quarter of a century he had devoted himself to the arduous labor of a country practice, and by faithfulness in the discharge of his duties had gained the respect of his medical brethren, as well as the confidence of the people among whom he labored. His professional life, therefore, was a success. During the past winter he spent a few weeks in this city, and a large share of that time was consumed in study which would better fit him for the performance of his daily labors at home. It seems but yesterday that we held friendly converse together while wending our way to Roosevelt Hospital, and yet to-day he is dead. Dr. Root was an honored member of the Madison County Medical Society; a regular attendant upon the sessions of the State Medical Society, and always manifested a lively interest in whatever was necessary to maintain the dignity and honor of his profession.

W. M. C.

THE POPULATION OF FRANCE.—From the report for 1872 of the French Minister of Commerce, which has just been published, it appears that there were 996,000 births, 352,754 marriages, and 793,064 deaths in that year. The number of births was 180,879 in excess of the preceding year, but only 2.67 to every hundred inhabitants, whereas in the early part of the present century the proportion was 3.19 to each hundred. The illegitimate children formed more than 7 per cent. of the total number of births, and the department of the Seine, or in other words Paris, supplies four times as many of them as all the rest of France in proportion to the population, while the marriages contracted there are the least fruitful. Of the 352,754 marriages, 147,125 were preceded by a contract, and in 14,433 cases children born out of wedlock were legitimized. There were 3,889 marriages between first cousins, and 340 between uncles or aunts and nephews or nieces. No less than 202,439 of the contracting parties—79,860 men and 122,579 women—were unable to read or write. The number of deaths, 793,064 in all, was 71,256 less than in 1869, and this diminution is attributed to the fact that so many of the aged and the infirm succumbed to the privations undergone in 1870 and 1871. It has been ascertained that the war and the Commune cost France 589,000 lives. The statistics for 1872 show that the mortality of the female sex was less than that of the male, being 2.11 as against 2.28 per cent. Upon the other hand, there are more male than female births, though the preponderance is not so great as it was thirty-five years ago. The general mortality of France is 21 per cent. in the early part of life, 3.10 per cent. from one to five years of age, from which proportion it declines to less than 1 per cent. at five-and-twenty. From the latter age it gradually rises from 1.05 per cent. to 7 per cent. at seventy years of age, and to 22 per cent. at eighty-five. The deaths of twenty-two centenarians were recorded in 1872.

NEW JERSEY STATE MEDICAL SOCIETY.—As has been previously announced, the one hundred and tenth session of this Society will be held at Cape May City (N. J.), on Tuesday, May 23, commencing at 7.30 P.M. A special train will leave Camden on Tuesday, 3.30 P.M., and will run through in two hours and a-half, returning from Cape May on the 24th, at 3.40 P.M. Delegates receive a free pass over the road on these trains. The Pennsylvania Railroad Company have agreed to furnish excursion tickets for members attending the meeting. Dr. Pierson, of Orange, N. J., has the matter in charge. A report of the meeting will be made for this journal.

TOBACCO POISONING.—At Vercelli, in Italy, a recruit was to be examined by a Military Board as to his fitness for service. He swallowed a certain quantity of tobacco, probably to excite palpitations to be construed into disease of the heart. Two hours afterwards he died in agonizing pain.

PHOTOGRAPHY AND VARIOLOUS ERUPTION.—Dr. Ultzman, of the University of Vienna, in a paper read before the Medical Society of Lower Austria, on the "Use of Photography in Medical Science," said that an eruption of small-pox had been made evident by photography twenty-four hours before it actually came out. Although nothing was to be seen unusual on the skin of the patient, the negative plate showed stains on the face which perfectly resembled the variolous exanthem, and twenty-four hours later the eruption became clearly evident.

GRATUITOUS MEDICAL SERVICES.—Mr. HEYWOOD SMITH, of London, (*British Medical Journal,*) suggests a very sensible plan for preventing the abuse of medical charity, and for the protection of the younger members of the profession who may desire a consultation with experts. He says: "I would earnestly submit, therefore, for the consideration of the profession, the following plan: that the practitioner should give his patient a slip of paper or short

note, addressed to any hospital out-patient physician or surgeon, asking for his opinion on the case, both as to diagnosis and treatment; and I am sure that, not only would it never be refused, but the consultant would feel as much honored by such reference to him as if it were made for a richer patient. This plan would increase the confidence of patients in their ordinary medical attendant, and prevent them from going off on their own account to hospitals. It would decrease the labor of hospital physicians and surgeons. The work would be to them more interesting, and the great evil at present so rife would be materially lessened."

Giant Cells.—These bodies have just received some further elucidation through Prof. Bizzozero, in the examination of a curious tumor, which he calls a tuberous elephantiasis of the right labium majus, and which may be considered as an exaggerated hypertrophy of the corium. In one part of the tumor he saw a large number of giant cells, sometimes isolated, sometimes in groups, of various forms, and whose interior was filled with globules of fat; after the removal of which he noticed the presence of 2, 10, 15, and more nuclei in the centre of the cell. Besides these histological characteristics, Bizzozero demonstrated the derivation of these giant cells from the hypertrophy of the simple cells of the connective tissue, as he found in the tumor all the gradations, from the small normal cells up to the largest of the giant variety.—*Gaz. d. Cl. di Torino*, Feb., 1876.

Chlorate of Potash in Obstinate Infantile Diarrhœa.—Dr. Moncorvo de Figueiredo, in an article in the *Revista Medica*, of Rio de Janeiro, narrates the circumstances which led him to appreciate the efficacy of chlorate of potash in a case of obstinate diarrhœa that lasted eight months, in a child two years of age. A solution of the potash, which had been ordered for some other cases of throat trouble, was given to this child by mistake. The effect, however, was very beneficial, so much so that Dr. Moncorvo directed the medicine to be continued, and soon obtained a complete cure. The formula was: one drachm of the salt to five ounces of the vehicle; the dose: a teaspoonful every two hours.

Dr. C. Bonfigli, in the *Journal Il Morimento*, also extols the beneficial effects of chlorate of potash in cases of diarrhœa, which he calls *vaso paralytica*, of cachectic children. He refers to fifteen cases in which the chlorate was taken in doses varying between thirty and one hundred and fifty grains in twenty-four hours.—*Gaz. Medica da Bahia*—No. 1, 1876.

Kerosene and Diphtheria.—If the medical gentleman in Connecticut who has made the remarkable discovery that the burning of kerosene causes diphtheria, will write a paper upon the subject, and read it before the next meeting of the American Medical Association, the gas companies throughout the country will be under lasting obligations to him. If he will do this, he may rest assured that his paper will not be buried in the Transactions of that Association.

Dartmouth Medical College and Preliminary Education.—From the last annual announcement we quote the following:

"Applicants for admission must be eighteen years of age, and unless matriculants of this institution (Literary Department), or graduates of some reputable College, Academy, or High School, must pass an examination as to fitness for entering upon and appreciating the technical study of medicine."

The New Jersey Pharmaceutical Association met in New Brunswick on the 17th inst.

Cure of Snake Bites.—In Australia subcutaneous injections of ammonia are being used very successfully for the cure of snake bites. The Melbourne *Argus* reports several cases in which coma had set in. One case was of a woman whose body was growing cold when the remedy was successfully applied.

Spiritualism.—The Commissioners appointed by the Physical Society of St. Petersburg to examine the phenomena of spiritualism, have arrived at the following conclusion:—"That those so-called spiritual manifestations proceed from unconscious movements, or from a conscious imposture, and the spiritual doctrine is a superstition."

The Medical and Surgical Reporter of Philadelphia has reached its one thousandth edition. Its present editor is Dr. J. H. Brinton, whose qualifications for the responsible office are unquestioned. We hope he will live to see its two thousandth edition, and write his usual telling leader on that occasion.

Inhuman Treatment of a Lunatic.—Mr. Wyer, a surgeon at Eastwood (Eng.), was recently sentenced to three months' imprisonment for keeping his lunatic sister in an attic where there was no ventilation and no fire, and allowing her to be naked and in a filthy condition.

Guano as an Antiseptic.—The Captain of the ship *John Brice* and his son were drowned in the South Pacific Ocean, Sept. 10, 1875. Their bodies were packed in guano, and were delivered in this port May 7, 1876, and were found in a good state of preservation.

Dr. C. E. Brown-Séquard.—The University of Geneva, which has recently reorganized its faculty, has tendered the chair of Physiology to Dr. C. E. Brown-Séquard. M. Reverdin has been invited to the chair of General Surgery.

Professional Courtesies.—A practitioner of Portush (Ireland) lately sued at law a medical brother, an Indian officer, for an attendance on his wife. This preposterous claim is very justly condemned by the medical press of Great Britain.

Changes of Sex.—"The mode of reproduction amongst mollusca varies. Some, like the Valvatidæ, change their sex after a time, being at first male, then female."—*Harting, on Shells.*

New York Medico-Legal Society.—Hereafter the stated meetings of this Society will be held in the Hall of the Academy of Medicine, on the first Wednesday evening of each month.

The Pharmacy Bill.—The proposed amendments to the Pharmacy bill were not acted upon by the recent State Legislature.

The Minimum age for School Attendance in this State has been fixed by law at five years.

The Plague is decreasing in Mesopotamia.

Weekly Bulletin of the Meetings of Medical Societies.

Monday, May 22.—Medical Society Co. of N. Y.
Tuesday, May 23.—Yorkville Med. Association.
Wednesday, May 24.—N. Y. Pathological Society.
Thursday, May 25.—Brooklyn Pathological Society.
Friday, May 26.—N. Y. Medical Journal Association.

Original Communications.

KUMYSS, RUSSIAN MILK-WINE; ITS PREPARATION AND USE.

By ADELHEID LUKANIN, M.D.,

NOVGOROD, RUSSIA.

Kumyss, the national drink of the nomad tribes of the south east and south of Russia, has gained such an extensive therapeutical use in Europe, and especially in Russia and Germany, that it deserves to be brought to trial in this country, where the conditions are most favorable for obtaining it.

The hope to lead the attention of American physicians to that new curative agent has prompted me to write this article. I am most indebted for the material to the lamented Professor of Materia Medica, Dybkovsky of Kief, and to my late friend Dr. Anna Klimenum of Odessa, Russia, who died of consumption and was sustained a long time by the most appropriate use of kumyss.

I shall be very happy if my sketch evokes some interest among American physicians.

Historical and Ethnological Notice.—As is known, the eastern parts of Russia, especially towards the south, consist of endless prairies between the Volga and Ural, scarcely known even to the civilized part of Russia, and inhabited by nomad tribes, which know nothing about agriculture, but have large droves of cattle, camels, buffaloes, and especially an immense number of horses. These prairies, or steppes, are covered in summer with savory grass; and the herds graze there, passing slowly from one place to the other, followed by their owners, the nomad tribes, which seldom consist of many members, but oftener of a few families. They pack up their kibitkas, a kind of tents made of skins and felt, which are their dwellings in summer and winter time, and wander farther, prompted not only by necessity, but also by their wandering spirit. I think that Americans can better than any other people realize what a Russian prairie is: it is a sea of waving grass, which is so high, that a man in upright position is hidden by it. Seldom a hill is met with, never a mountain, and in the midst of it large, beautiful streams rolling their lazy waves towards the Black or the Caspian Sea. Not a human being is to be met for several days and even weeks by the solitary traveller; not a road, not even a path; in the day the burning heat of an almost tropical sun; in the deliciously fresh and even cold nights, myriads of stars in a sky of a deep blue, unknown in other regions. In winter time, nobody excepting the nomad dares to cross the snow covered desert.

By chance the traveller meets a camp of Kirghizes; he is quite astonished to see the bright-looking, healthy people, neither too beautiful nor too clean, but happy. He inquires about their mode of life, and they readily tell him all about it, and that their food consists of plenty of meat and milk, especially of the latter, which they prepare in different ways, among others as kumyss. This production, having been quite unknown to the Russians, it is only natural that it was to the mysterious drink that the health of the nomads was solely ascribed; but their living always in good fresh air, and having work and rest at their own leisure, in reality contributes largely to this result. Be it as it may, the sedentary Russians, settled on the western confines of the steppes, sent their invalids in summer-time to visit their wandering neighbors, and gather strength by drinking kumyss. They drank freely of it and, *post hoc ergo propter hoc*, spoke of Kumyss as of the agent of their sometimes almost wonderful cures. At last, about twenty-five or thirty years ago, physicians, and lately chemists, grew so far interested in the subject that scientific researches were made, both of clinical and experimental character, and great establishments were founded throughout Russia, where thousands now seek and sometimes find health, or at least relief for a given time from their sufferings; as, Dr. Stahlberg's cure-house near St. Petersburg, Russia, where kumyss is prepared from mare's milk, and others in middle Russia and in Krimea, in some of which cow's milk is used. Such cure-houses are also established now in Germany; so in Austria, near Vienna, in Trautmannsdorf; in Davos, in the Rhetish Alps in Switzerland, and in many other places.

Wisk, in Bremen, and Schnepp, in Eaux-bonnes, have written about kumyss. In France it was unknown till 1867.

Preparation of Kumyss.—Kumyss (*Vinum lactis, Lac equinum fermentatum*) is prepared by the fermentation of mare's milk. The fermentation of milk-sugar produces alcohol, carbonic acid, and lactic acid, and to these products the action of kumyss seems to be chiefly due.

The analogy between the vinous fermentation and that of kumyss gives us the right to call kumyss a milk-wine. It is prepared in three different kinds of vessels: in wood, well dried skins, and clay. In these vessels the mare's milk is fermented by means of sour dough or other ferments. In most cases, as ferment, is used old kumyss or a sediment from old kumyss which has been dried in the sun or over a slow fire, and is called kor.

Half a pound of kor is dissolved in two bottles* of fresh mare's milk, but before this solution is used it is left standing till it gets sour. Where there is no such ferment at hand, an artificial one is prepared from fresh yeast, wheat, or other flour, or honey and milk; from these a dough is made, and when it begins to rise it is wrapt in clean linen and put in fresh milk. When the milk becomes sour, the dough and the milk might both be used as ferment.

Another ferment again is the ordinary milk itself. The casein, before it coagulates, has the property of inducing the alcoholic *fermentation* of sugar at a temperature between 28 and 40°R., but at the same time at this temperature, before the sugar is changed into alcohol, lactic acid is formed, the casein coagulates, is precipitated, and the alcoholic fermentation is checked.

This is the process we meet in the ordinary souring of the milk.

I am not responsible for this statement, which expresses the current view held by the majority of authors who have written about kumyss. One thing is sure, that lactic acid, as soon as it is formed in greater quantity, seems to deprive the natural ferment, be it casein or any kind of animal or vegetable microscopical beings, of its property to induce the alcoholic fermentation.

The Baschkires and Kirghises of the steppes counteract this by adding to the milk one third of spring water which is more or less alkaline, and continually stir the milk, as contact with air seems to be very favorable to the formation of kumyss. Only in cases where the fermentation does not begin at once, they

* A bottle is a measure containing about 600 to 650 grammes of water, at the ordinary temperature.

use a piece of rye bread as a ferment. Some tribes use alcohol and yeast, a copper coin, a piece of fresh horse-flesh or a fresh tendon, etc.

The principal manipulation, of which there are several, either to arrest or to promote the fermentation, consists, as mentioned above, in stirring the milk, which prevents coagulation and settling of casein, and rising of cream.

Kumyss may be prepared of different strength, according to the time it has fermented and the quantity of sugar that the milk contained. Different kinds of milk might be used. The best after mare's milk is ass's milk. Goat's milk contains too much casein, which predisposes to putrefaction, and not enough sugar. Cow's milk is good, with an addition of sugar and water. Even the nomads in preparing kumyss, which serves them sometimes to intoxicate themselves, add cow's milk when mare's milk is wanting.

Description of Kumyss.—Kumyss is a milky fluid of a sweetish acidulous taste, which reminds one somewhat of sour cream. The taste of old and fresh kumyss is different. Fresh kumyss is sweeter and contains less carbonic acid and alcohol; the old is sourer, has more alcohol, and so much carbonic acid that it reminds one of soda-water. In standing, kumyss separates into two layers; the upper is clear, the lower is cloudy, containing the finely divided casein. Fresh kumyss is milky; old, clear. Its smell depends upon the cleanliness of the animal from which the milk is contained, and the cleanliness of the preparation. There is almost no odor at all, if the laws of cleanliness have been observed. Kumyss prepared in spring is poorer in alcohol, and has a somewhat aromatic odor depending upon the fresh grass and flowers eaten by the animal.

The relative quantities of chemical constituents depend not only upon the mode of preparation, but also upon the condition and nourishment of the animals which give the milk. For instance, with more exercise, the quantity of casein increases; with rest, the fat; when nourished with oats, the milk-sugar, etc.

It may be the place here to say a few words about the way in which some of the establishments founded abroad manage to have good kumyss, and the difficulties with which the obtaining of genuine kumyss is accompanied. So in Dr. Stahlberg's establishment near St. Petersburg, and even in Trautmannsdorf near Vienna, the horses, and the persons who take care of them and prepare kumyss, have been brought in from Tartaria, as the milk of the steppe horses could alone —as was thought—give genuine kumyss; but it was found that even with all these precautions kumyss prepared in the latter way, seems to differ from that of the steppes; according to the physicians who have tried both, it is not borne as easily and has not the same beneficial influence, which may depend upon the different climate, mode of life both of patients and horses, and different kind of food for the horses. Lately the Tartars have been replaced in Trautmannsdorf by Germans, who have learned to make kumyss very well, and at any rate in a cleaner way than the Tartars. The buying, bringing, and keeping of steppe horses is very expensive, especially if we take in consideration that their mode of life must be as much as possible like their mode of life in the steppes; they must have extensive grazing grounds, and be able to range freely from the melting of the snow in spring until it again covers the ground; they must never be separated from their young, because a mare will not give any milk if it loses its young. In the winter young and old horses are gathered in a large yard, and are nourished with hay, flour, and fresh water. In summer they graze as stated above.

A mare is milked six times a day in summer, and once a day in winter. Each gives from one to six litres of milk a day.

Kumyss from cow's milk prepared and analysed in Warsaw:

Alcohol, 1.23 per cent. fat, 0.52; sugar, 1.77; lactic acid, 0.63; casein, 3.08; salt, 0.63; carbonic acid ? (whole quantity of solids, 7.67.)

This analysis shows that in kumyss 2 days old, not the whole quantity of sugar is changed into alcohol and carbonic acid.

The fermentation once begun goes on, even if kumyss is put on ice, till all the sugar is changed; this lasts about 6 to 8 days. Such kumyss, besides containing more alcohol, is also sourer.

Kumyss made in September and kept in an ice cellar till February, showed the following relative quantities of constituents:

Alcohol, 3.23 per cent. [which corresponds to about 6 of milk-sugar]; fat, 1.01; sugar, 0.00; lactic acid, 2.92; casein and salts, 1.21; carbonic acid, 1.86; whole quantity of solids, 5.14.

The chemical process in the production of kumyss is the following: a given quantity of milk-sugar under the influence of a ferment, and at a temperature between 20° to 40° is changed into a glucose,* which farther is changed into alcohol and carbonic acid. Besides this, we find some other not essential products of fermentation and lactic acid. As kumyss of middle strength is usually given, I will give the results of Gartier's analysis of a kumyss two days old:

Alcohol, 1.65 per cent.; fat, 2.05; milk-sugar, 2.20; lactic acid, 1.15; [whole quantity of solids, 6.80.] casein, 1.12; salts, 0.28; carbonic acid, 0.785; [which correspond to 3.22 of milk-sugar.]

The albuminous constituent parts are found mostly in a soluble modification.

Physiological Action of Kumyss.—In small doses, *i.e.*, about two or three tumblers, kumyss produces only a feeling of warmth in the stomach; strong kumyss produces besides this an effect like champagne, soda-water, or seltzer-water, owing to the carbonic acid that it contains. It is borne by the stomach more easily than milk; if two or three bottles of milk or water are drunk daily, they produce a disagreeable feeling of fulness and heaviness in the stomach, which is not the case with kumyss, owing to its ready absorption promoted by the presence of alcohol and carbonic acid. Some nervous and sensitive patients have an idiosyncrasy against kumyss; sometimes, without any prejudice against it, a few glasses produce nausea and vomiting. Such an idiosyncrasy may be in some cases mastered; patients grow used to it, especially if they begin with very small quantities,—they even grow fond of it; but sometimes the idiosyncrasy persists, and the treatment cannot be continued.

If kumyss is used in large quantities, there appears a feeling of discomfort, of apathy, and even sleepiness; a kind of intoxication of a low degree.

Notwithstanding that with kumyss a large quantity of nourishing substances is brought into the system, the appetite is not impaired, the patients take their meals regularly and with pleasure. Fresh kumyss produces rather looseness of the bowels; old kumyss constipation. This is very important in giving means to regulate the action of the bowels throughout the treatment, in giving alternately fresh and old kumyss.

* Dilute acids change milk-sugar into a peculiar glucose called galactose, which is directly fermentable; it is possible that lactic acid in small quantities has the same property of changing milk-sugar into galactose.

If the tongue was coated in the beginning of the treatment it cleans in a few days.

Absorption of kumyss is easy and almost complete, only a small quantity of it being excreted with the fæces; more, although not very much, by the skin and kidneys.

Kumyss is not a diuretic in the true sense of the word, although the salts and the great amount of water that it contains have an influence on the daily excreted quantity of urine. There are no records of analysis of the urine from patients treated with kumyss; it is very likely that there are changes in it depending upon the increased quantity of water and nourishment taken into the system.

To this increase of nourishment must be attributed the increase of weight of the patient, beginning to appear in the second or third week of the treatment; if this is carried on six or eight weeks, the increase amounts to about 20 lbs.

The skin becomes clearer, and its color brighter and healthier.

If strong kumyss is used, the pulse increases in frequency about ten to fifteen pulsations in a minute; as soon as the patient grows used to kumyss the pulse becomes again normal, just in the same way as if another alcoholic drink was taken.

The respiration is also more frequent and impeded by the distention of the stomach. The sputa if present —become more profuse, more liquid and frothy; —all secretions are more liquid owing to the greater amount of water taken into the system. Some authors assert that kumyss has an influence on the genital system; that men grow more excitable, and women menstruate oftener and the discharge is increased in quantity. This may depend upon the diuretic influence of kumyss irritating the kidneys, bladder, and urethra, from which the irritation is reflected to the genital system—or upon the better nourishment making the genital system more active. Some excitement is produced in the beginning in the nervous system, especially in patients not accustomed to alcoholic drinks, which is followed by drowsiness. A few patients, however, grow excited in such a measure that they totally lose sleep. Patients who have disease of the heart begin to suffer from palpitations, so that it is either necessary to use morphia or to abandon the treatment at once.

Dr. Polubensky, in Russia, states that after a protracted use of kumyss, there may appear an exanthema very like urticaria, and painfully itching, which fast subsides on the use of acetate of morphia, and seems therefore to be simply of a nervous character.

We might infer from what has been said above, that kumyss has no specific influence whatever on the system, its power consisting chiefly in the greater amount of nourishment brought into the system under conditions of either solution or fine division, promoting its easy digestion and speedy absorption. However, let us consider its chief constituent parts; and, first of all, the alcohol.

The following qualities, shared more or less by all the alcohols, are:

1. In small quantities it promotes absorption, as has been proven by Claude Bernard.

2. It saves the fatty and also the nitrogenized substances from oxidation.

3. It promotes both secretions and excretions.

The qualities under heads 2 and 3 have been beautifully illustrated by Professor Setschenoff's experiments in St. Petersburg.

4. It excites and heightens the nervous actions—which in some cases might not be desirable at all.

I must add here a few words about the sleep induced by kumyss, and which is very likely to be attributed to the alcohol. In general it seems that there is comparatively too much attention given to the temperature of the body in diseases, and not enough to sleep. At the same time, the experiment of Niemeyer, Pettenkofer and Voigt have proved what an immense influence sleep has on the exchange of matter in the living organism.

They showed that the system gives out more carbonic acid in the day-time, and takes more oxygen in the night during sleep; in this way the larger quantity of oxygen exhaled in day-time is replaced in the night, and the patient awakes refreshed and rested. 5. Alcohol lowers the temperature of the body and increases the power of the heart. Let us consider farther the milk-sugar and the lactic acid.

Professor Botkin, in St. Petersburg, made experiments which proved the beneficial influence of milk-sugar upon nutrition. He states that the weight of patients increased after a treatment with milk sugar. I think that it may be interesting to mention that Arabian physicians have used milk-sugar in the treatment of consumption.

Frank compares the action of lactic acid to that of the organic salts; it lowers the temperature of the body and decreases the frequency of the pulse, which makes its use desirable where fever is present. Reich ascribes to this acid tonic, antipyretic, and diuretic properties. The casein is present in kumyss in a soluble form, and also in an insoluble; but then it is very finely divided, which has been stated above, so that it is unnecessary to dwell upon it longer.

As to the carbonic acid, it lowers the rapidity of the heart's action by influencing the inhibitory filaments of the pneumogastric nerve, and acts locally on the stomach as a tonic.

Therapeutical Use of Kumyss.—1. Kumyss is given in disease of the digestive organs, as catarrhs, chronic diarrhœas; in all diseases gathered under the head of dyspepsia; in the period of convalescence from typhus and dysentery. It does not increase the difficulty of digestion, and this explains partly its beneficial influence.

2. In disorders of the respiratory organs, and especially in consumption, I feel obliged to make here a digression about the hygienic treatment of consumption in general. An idea very popular now in Europe is, that production and storing up of fat in the organism is a preservative and even a curative agent in diseases of the lungs, especially in phthisis or protracted specific catarrhal pneumonia, with deposits of inspissated catarrhal secretion, or cheesy matter, *i.e.*, yellow tubercle; that is in the so-called scrofulous form. The better nutrition, the formation of fat, prevents the wearing out of the organism, and gives it the possibility of outliving, so to say, the slow inflammatory process going on in the lungs, and to attain the period of retrogressive metamorphosis of the cheesy matter, consisting in softening, emulsification, and absorption of the tubercle. The absorption once accomplished, cicatrization might follow. These statements are not merely theoretical; old cicatrices are found in the lungs of patients who died from other diseases, and where there had been for some years a notorious disease of the respiratory organs, which had subsided under treatment. I think that in many a case of consumption, death occurs, not from the impossibility of breathing, but from the exhaustion occasioned by the slow consuming fever, which kills here, as it kills in protracted suppurations, etc.

This statement implies another, namely, that all hy-

gienic curative agents like kumyss are invaluable in consumption. Its use in Russia has been brought into practice by the observation how wonderfully soon the constitution of the nomad, which had been lowered in the winter by bad hygienic conditions, becomes again healthy and brilliant in summer, and by the idea that those nomads never suffer from consumption. The first observation was perfectly right; the second based partly on a mistake. It is true we find less consumption among those tribes, but this is mostly due to the dying out of the weak children, so that only those remain that are mostly fitted to their rude mode of life. For this reason also we find less scrofula among them.

Kumyss is especially very useful in the beginning of phthisis; it cannot do much if the patient is already in the stage of diarrhœas and colliquative sweats.

If kumyss is taken steadily in other chronic lung diseases the nutrition grows also better; the patient gains flesh and feels stronger. In patients inclined to hæmoptysis the blood-spitting appears again with the use of kumyss, even if it had ceased before the beginning of the treatment, but this is not a contra-indication altogether; if the hæmoptysis is not violent, one can continue the treatment, and give either weaker kumyss or interrupt it for some time; even if the treatment is continued without change, the hemorrhages usually subside after some time. Kumyss is not so useful in cases attended with hectic fever.

Dyspnœa grows better after some time; the expectorations become easier, which explains the usefulness of the remedy in chronic bronchitis, both in the idiopathic form and in that attending emphysema of the lungs.

3. Kumyss is very useful in anæmia and chlorosis; in short in all conditions of defective nutrition: as in protracted suppuration, prolonged lactation, in convalescence from fevers, in scurvy and its allied diseases, in hypochondria, in hysteria accompanied by anæmia; and, as stated above, in diseases of the digestive organs.

4. It has been used in nervous diseases, but here its influence is not well known; at any rate, it might do well in functional nervous diseases complicated with anæmia.

1. *Contra-indications.*—Kumyss is not to be given to plethoric patients inclined to apoplexy, and to those who possess a strong tendency to hemorrhages, remembering the stimulating effect of the remedy and the increase of pressure in the blood-vessels produced by it.

2. Nor in diseases of the heart.

3. Nor in diseases of the kidney and bladder, as it irritates them.

4. Nor in pronounced acute and chronic febrile diseases, although it can be given in the time of convalescence from them.

6. Nor in gout.

7. Nor in pregancy.

8. Nor in organic nervous diseases.

9. Nor in the last stages of consumption. But we may recall the properties which have been claimed for kumyss, and administer or withhold it according to the indications.

These properties are briefly the following:

1. Promotion of the formation of fat and promotion of sleep—due to alcohol.

2. Promotion of nutrition in general—due to milk-sugar.

3. Lowering of temperature and pulse—due to lactic acid and alcohol.

4. Renewal of the wasted albuminoid parts—due to casein.

5. Lowering of the frequency and increasing of the power of the heart's action—due to carbonic acid.

6. Tonic action of the carbonic acid.

7. Diuretic effect of the greater amount of water and salts introduced into the system.

We do not find all these qualities combined in any single article of food or medicine except kumyss.

Dose and Form.—The dose is the largest quantity that may be taken without injury: four to six or eight bottles a day. I think that more would be scarcely possible.

The use of fifteen bottles, or of only two to three tumblerfuls, would alike be useless, and the first even injurious. The diet should be mixed and substantial; vegetables and fruits are to be recommended; if needed a small quantity of strong wines or liquors may be given; better avoid them. Tea and coffee may be taken or not, as the patient is used to them; if anything is taken, coffee is to be preferred, as having a very good tonic influence in the rare cases where kumyss impairs digestion but rhubarb in small doses has the same tonic effect. Some authors recommend a meat diet as the most suited to the treatment. Exercise is to be advised. Kumyss is to be drunk from June till September.

The course of treatment is usually begun with two to three tumblerfuls a day, increased gradually to several bottles, and carried on about six to eight weeks; but it is more beneficial when prolonged, because of the comparatively little good done by kumyss in the first weeks. Some patients, although not liking kumyss in the beginning, become quite fond of it in time, as stated above. It can be given also in the winter, only it must be kept in mind that patients perspiring more freely when taking it, care must be taken not to expose them to draughts.

Kumyss prepared from Cow's Milk and Artificial Kumyss.—These kinds of kumyss are prepared in different ways.

1. From fresh warm cow's milk: the milk is diluted with one-third or one-quarter of water, and one tablespoonful of cane sugar is added to each bottle of milk (a bottle contains from 600 to 650 grms. of water at the ordinary temperature), and a bottle of ordinary yeast. It is still better to add one-quarter of a bottle of old kumyss, if it is to be had; then the whole mixture is put into thick beer bottles, well stoppered, and placed in a cellar; it must be from time to time agitated, to prevent the coagulation of casein. In three days the kumyss is ready, and must be drunk when fresh; as prepared in this way it does not keep a very long time.

2. Skimmed milk might be used without being diluted, and kumyss prepared in the same way as above.

3. Instead of diluting the milk with water, it might be diluted with whey.

4. Dr. Schwalbe gives a recipe for the preparation of artificial kumyss as follows: 100 grms. of condensed milk are dissolved in 1½ litres of water, 15 grms. of alcohol, in form of rum or cognac (brandy), are added, also 1 grm. of lactic acid or 0.5 grms. of citric acid, and this is saturated with carbonic acid in the usual way for preparing soda-water; the mixture must be well agitated, being in the soda-water apparatus, and the kumyss is ready after 24 to 48 hours.

5. Recipe for the preparation of kumyss given by Professor Julius Trapp, in St. Petersburg:

Take 24 lbs. of mare's milk and 4 ounces of honey, and mix them.

The yeast to be added is prepared in the following

way: 1 ounce of semen-panici miliacei reduced to flour, 1 ounce of beer-yeast and enough milk added to make a semi-solid mixture, which is put in a linen-bag and immersed in the mixture of milk and honey. The whole is covered with a cloth and exposed for 24 hours to a temperature of about 30 to 35 R. Then the liquid is strained, put in bottles of thick glass, well corked, and put in a cold place, because kumyss acts like soda-water or champagne, owing to its great amount of carbonic acid, and may burst the bottles.

Professor Trapp advises making kumyss from cow's milk to which ¼ of water has been added.

We have seen above that this additional quantity of water is variable as well as the temperature at which kumyss is to be prepared, according to different authors.

In general the subject is not as yet sufficiently studied; although it deserves, as it seems to me, to be thoroughly tried, as possessing many a valuable quality.

HYPERTROPHY OF THE SPLEEN SIMULATING OVARIAN TUMOR.

By DAVID F. KING, M.D.,

NEW YORK.

The following case, though not without interest in a pathological point of view, is especially so in a diagnostic, and shows the difficulty of making accurate diagnoses of the different kinds of abdominal tumors presented to our notice.

Catharine Brown, æt. 31, M., England; housekeeper by occupation, and quite intelligent. She came under my observation Nov. 19th, 1875, when living in the upper portion of this city, in a somewhat malarious neighborhood. Family history good. With the exception of an attack of malarial fever of ten months' duration, ten years ago, and what appears to have been general anasarca with ascites, which lasted nine months, nothing worthy of special note could be ascertained previous to present illness; was delivered of a child six years ago, which lived two months, then died of what was said to be "enlargement of spleen;" an autopsy being held. She lost another some time after in the same way.

Three and a half years ago was delivered of seventh child. Labor perfectly normal.

She was in the enjoyment of exceedingly good health for three months after, when, following great exposure, she was taken with sharp pains in the region of the spleen, and in this situation, at the same time, noticed a lump about the size of a tea-cup. A physician of St. Louis pronounced the spleen affected. The lump kept gradually enlarging downward; slowly pushing its way towards the right side, and over the abdomen, changing in shape seemingly; sometimes round, sometimes oblong, etc. It would not remain stationary but would fall to the right when she turned towards that side; was seen by an eminent physican of Chicago and treated for "tumor of womb;" others pronounced it the same, while another skilled gynæcologist in the same city told her it was "enlargement of spleen." Has never had any pain in the growth since. When she took exercise it would seem to become smaller, returning to original size after exertion had ceased. When having her courses the lump would increase in size, and go down after their termination. Menses ceased six weeks ago, and have not come on since.

Suffered from "piles" twelve years ago, which bled once a month, also from external hæmorrhoids since she has had the tumor, which caused much pain and from which she has lost blood at times. Lower limbs commenced to swell slightly about two years ago, and a year ago increased considerably in size. Has retained flesh and strength, and been pretty well up to about three months ago, when she began to grow weak and passed but little water. At this time suffered from pain in right hypochondriac region of so severe a character as to oblige her to remain in her room for three weeks. She noticed no enlargement of right side.

She entered Mt. Sinai Hospital, Sept. 24, 1875, and while there was seen by many the ablest practitioners of this city. The principal symptoms noticed during her stay there were: passage of blood from the bowels; failure in flesh and strength; night sweats and high temperature; average about 101°. The highest was 105°, lowest, 98°. The diagnosis made was: "Lympho-sarcoma of the omentum."

Has suffered from epistaxis off and on for the last three weeks. About two weeks ago began to cough and expectorate yellow phlegm.

Present Condition.—Patient emaciated and excessively anæmic in appearance. Is suffering from cough, with expectoration of yellow phlegm; night sweats loss of flesh and strength, and impeded locomotion, in consequence of weight in and enlargement of the abdomen. Physical Examination: Pulse 120 (feeble and compressible); resp. 24; temp. 100.

Lungs and Heart.—Nothing worthy of special note. Former gives evidence of bronchitis. Action of latter feeble; impulse weak with sounds indistinct.

Abdomen.—Patient lying on her back; a tumor presents about the size of uterus at full term, freely movable, with well-defined edges. It extends from left to right, and has about the middle of upper border quite a deep depression. The lower part can be lifted, and is more rounded to the hand.

The tumor is smooth and somewhat elastic to the touch. Percussion gives dulness all over the mass. By a *bimanual palpation* the uterus is found separated from the tumor being freely movable, and of normal size. The mass cannot be felt through the vaginal walls.

Lower Extremities.—Tender, with well-marked pitting on pressure; swollen.

Urine.—Amber; acid; slightly albuminous with urates; granular matter; no casts.

About two weeks after this the woman was seen by a prominent gynæcologist of this city, who, after an examination, thought it was adeno sarcoma of the left ovary, but was not positive in this diagnosis, and proposed an exploratory incision, if the woman made up her mind to enter a hospital. The other physicians present at the time did not express positive opinions, but were inclined to believe it was "enlargement of the spleen."

Dec. 3d.—Dr. Whitall saw the case in consultation with me. It (the tumor) is concavo-convex in shape, the concavity pointing upward and to the left, the convexity downward and to the right. The lower margin can be felt also, and is found to be fissured in two situations, which makes the tumor resemble very closely the liver. The spleen, by auscultatory percussion, cannot be detected in its normal position. There is a continuous line of dulness extending from the liver down. The tumor is determined to consist of spleen, with perhaps involvement of the liver. From the tumor being so movable, however, and from dulness having existed in the hepatic region when the mass was on the opposite side, the latter is doubtful.

Microscopical examination of the blood revealed no increase of white corpuscles. The majority of the red corpuscles were indistinct, with ill-defined outlines; some very much shrunken in appearance. By focusing, however, the bright centre and dark border could be obtained; also the biconcave appearance. In some parts of the field they would form in rouleaux, while in others they evinced no tendency to do so. The blood, when flowing from the scratches in the arm, was thin and of a watery appearance.

Dec. 18th, 3.30 P.M.—Great weakness from excessive epistaxis. Looks completely exsanguinated; lips and gums very pale; tongue light in color and coated on dorsum; surface of the body covered with a profuse cold perspiration. Pulse 132. Resp. 28. Temp. 101.2. Is taking stimulants freely.

Dec. 25.—Patient is failing rapidly. Slight epistaxis yesterday, which ceased after the application of liq. ferri persulphate. Pulse very feeble, 136. Resp. 28. Temp. 101.5. Patient died about 3 A.M. on the 27th.

Necropsy, 35 hrs. P.M.—Rigor mortis slight. Body emaciated. Abdomen only examined, and that imperfectly, in consequence of the presence of the husband, who with great reluctance permitted *any* examination. The tumor was observed to have remained almost entirely on the right side. It was clearly an enormous spleen, turned upon itself, with the hilus presenting upward and to the left. The surface of the organ was smooth. It was of solid consistence and of a bluish color, with the peculiar elasticity to feel common to the spleen. The fissures noticed were those peculiar to the spleen; but greatly exaggerated. No section could be obtained.

The organ was supposed to be, by the physicians present, fully twelve pounds in weight. The omentum was perfectly normal in appearance; very little adipose tissue found. The glands were not investigated thoroughly, as no further examination could be made. The liver was pushed up by the tumor. It seemed to be of normal size, but very pale in appearance. Small amount of fluid in lower portion of abdomen.

The case presents in many respects great resemblance to one of splenic lukæmia. The gradual enlargement of the organ, without attacks of intermittent fever, or without constant exposure to malaria; the development of languor, debility, and great pallor of surface without any other appreciable cause; the occurrence of hemorrhages from the nose and bowels; œdema of the extremities: absence of *marked* emaciation; change in the blood, though certainly there was seemingly no reduction in the number of red corpuscles; all *point* to this form of lukæmia as the cause of the patient's death.

No. 1113 Second Avenue, New York.

The Bordeaux Medical College.—The municipal council of Bordeaux voted unanimously on the 25th of February, the sum of $500,000 to defray the expenses of installation of the new College. The mayor is authorized to purchase in the name of the city the Hospital for Incurables, and the Maternity, both situated on the east side of the *Place d'Aquitaine*. The construction of the new Faculty will be determined by a "concourse."

A New Pavement.—The *Revue Scientifique* speaks of a new pavement which is about to be tried in Paris. On a bed of masonry a layer of asphalt is spread, in which blocks of cast-iron one and a half inches thick are imbedded. It is a sort of iron mosaic.

A CASE OF HERPES ZOSTER, WITH HYPERIDROSIS, TREATED BY ELECTRICITY.

By FREDERICK WILLIAM GODON, A.B., M.D.,

San Francisco, Cal.

Peter D., æt 43, married, a native of Germany, miner, of blonde complexion and exceedingly nervous temperament, sent for me Jan. 3, 1876, to consult me in regard to an eruption which had appeared three days before. The vesicles—for the eruption was herpetic—first made their appearance in the groin, above and below Poupart's ligaments, and in the lumbar region; then on the right side of the scrotum, and in the corresponding nates, continuing downwards on the front of the thigh, the lowest vesicles being about three inches above the knee. The gentleman in attendance prior to my being sent for had pronounced the case one of sciatica, and had prescribed a liniment, and had given morphine internally to assuage the pain. The eruption was preceded by the most acute pain. Most if not all of the superficial branches of the lumbar and sacral plexes were involved. The nature of the pain following the evolution of the exanthem was severe and shooting, extending from the hips to the knee, exaggerated near the spine, and again cutting and stinging, running along the groin towards the penis. The pains, although never entirely absent, were distinctly remittent. The parts covered by the eruption were literally bathed in a most profuse and oppressive sweat, as indeed was the entire right side of the body. The patient gave a good family history, denied any venereal taint, was not an habitual drinker, although within the last three months, during which time he had suffered from several attacks of trifacial neuralgia, he confessed to have indulged rather immoderately in alcoholic stimulants, which he thought relieved his pain at the time. He had suffered from a severe attack of rheumatic fever six years ago. He was weak and anæmic when I saw him, without appetite, and in great pain; and, as a consequence, irritable. The locality of the eruption points decidedly to the conclusion that in this case, if not in all cases of *herpes* zoster, the primary lesion is central, and in all probability seated in the ganglia of the posterior roots of the nerves of the affected side.* The unilateral hyperidrosis, which was well marked, was undoubtedly owing to nervous debility brought on by great mental anxiety and worry.

Inasmuch as the patient's stomach was exceedingly irritable, I prescribed no medicines internally, with the exception of quinine in two-grain powders every four hours. Galvanism was immediately resorted to for the alleviation of pain, and applications were made both locally and centrally, to the immediate relief the patient. Sixteen hours after the first application of the galvanic current the patient passed a quiet night, and on the following morning was entirely free from acute pain, although there still lingered a diffuse tenderness over the lower lumbar vertebræ and in the neighboring region. The patient was again galvanized centrally, and left feeling quite comfortable. After the third application, made at the expiration of thirty-six hours, the patient said he felt quite comfortable, and noticed that the eruption appeared to be fading. He continued to improve under the treatment; the eruption had entirely disappeared at

* *Vide* "Anstie on Neuralgia," *Reynolds' System of Medicine*, Vol. II., page 737.

the expiration of six days from its first appearance, no excoriations having taken place. Quinine was continued throughout the electrical treatment. All hyperidrosis ceased after the third application of electricity, and the eruption disappeared very rapidly.

I have been led to present this case as one more illustration of the neurotic relation and origin of true zoster, and also as an example of the successful use of the electric current in the treatment of skin diseases either dependent on or in connection with diseases of the nervous system.

Trifling as it may at first appear in its clinical features, it strikes me as worth recording, if it should lead to nothing more than adding another example of the very important and close connection of many dermatological lesions and disorders of the nerves, and in the successful treatment by electricity long so potent in purely nervous diseases, but which now is beginning to claim so high a place in cutaneous therapeusis.

SAN FRANCISCO, CAL., 104 Montgomery St.

Progress of Medical Science.

GALVANO-PUNCTURE SUCCESSFULLY USED IN ANEURISM OF THE FEMORAL.—Dr. Hauck reports the following interesting case. The patient, a man forty years of age, presented himself with a round tumor five inches in diameter, situated at the middle and inner side of the left thigh. A pad was first applied, and then digital compression, but both plans failed. It was then decided to use the galvano-cautery. Three platinum needles, connected with the negative pole, were plunged two inches deep into the sac, their distance apart being half an inch. The circuit was completed by attaching the positive pole to a metallic plate placed above or on the surface of the tumor. The continuous current was thus employed for about twenty minutes. After the second day the tumor became softer, and three clots of blood, each the size of a pigeon's egg, were felt. The pulsation and murmur had diminished. Five days afterwards the same operation was performed on the other side of the sac. After eighteen hours no pulsation or murmur could be detected, but there was inflammation, the pain being very great. Ice was ordered, but being applied too energetically by the attendant, gangrene of the skin resulted, a portion of the skin sloughing away in a few days, and with it the covering of the tumor. A large coagulum was thus exposed to view, and extending over it was the saphenous vein, which, stretched by the mass of blood, accounted for the intense pain. This also broke away, and a mass of coagulum was brought to view, which was gradually removed to the extent of about three ounces daily. The hemorrhages were controlled by ice. The cavity, after being cleansed, was filled with charpie-balls dipped in a solution of salicylic acid. This treatment was continued for six days, when the Doctor removed the coagulum in all directions, and he thinks the mass did not weigh less than two pounds. Five months after the operation, the wound was entirely healed, leaving a small contracted scar, slight stiffness at the knee-joint, and some anæsthesia of the lower portion of the thigh and inner side of the knee.—*St Louis Medical and Surgical Journal*, April, 1876.

OTIS'S OPERATION IN THE TREATMENT OF INCIPIENT STRICTURE.—Mr. Berkeley Hill, of London, has devoted a clinical lecture to discussing the chief points brought forward by Dr. Otis in reference to stricture of the urethra. Within the past year Mr. H. has measured ninety five urethræ, all of them with some urinary disease, and in only three did he find the meatus as wide as the rest of the canal. The measurement of these urethræ has been under-estimated, and he thinks Dr. Otis is correct in claiming larger calibres for that canal. He has not, however, found the distensibility to be uniform from the bulb to the meatus. The urethra is widest at the bulbous part, and remains of an even width for about two inches, and then it gradually narrows, and for the rest of the canal it is about three millimetres less, the narrowest portion being at the outlet. This, he says, agrees with the description of anatomists, except that the distensile capacity of the urethræ, measured in the living body, showed greater limits than they set down. The spongy urethra is conical in shape, resembling the tapering nozzle of a syringe, which is designed in this way, probably for the conduct of the semen. That stricture in any shape is the sole cause of gleet, he rather doubts, though doubtless it is the most frequent condition. His own experience does not support the statement of Dr. Otis that strictures are generally met with in the first inch and a quarter of the urethra. In sixty-three cases examined by bulbous sounds, Mr. Hill found forty-three to be between four inches and one half to six inches. In one hundred cases published by Dr. Otis, thirty-one patients were found without contraction, when examined a considerable time after the operation. Fifty two others were not examined, but reported themselves as well; the remaining seventeen were not quite cured, though relieved. This evidence induced Mr. Hill to give a trial to this method. He took sixteen cases of long-standing gleets, with one or more contractions in the spongy portion of the urethra. Dr. Otis operated upon one, and Mr. Hill upon the remaining fifteen. In five cases the gleet ceased after the operation, and the patients were cured; but of these five the operation proved serious to two, one having hemorrhages for three days, and the other three attacks of rigor. Of the remaining eleven, among which was Dr. Otis's case, the gleet persisted in all; in this last case being cured by other remedies. Mr. Hill advises the avoidance of the use of instruments whenever the gleet has been of short duration. The exact length of time that indicates stricture is uncertain, but as a rule the canal should not be searched when the discharge has only lasted six months.—*The Lancet*, April 8, 1876.

TORSION OF ARTERIES.—Since 1871, M. Tillaux has not ligated the arteries in his operations, and in over one hundred major operations, in which he has employed torsion, he has not had a single case either of primary or of secondary hemorrhage. In a memoir on this subject, read before the *Société de Chirurgie*, he draws the following conclusions:

1. Torsion is applicable to all arteries, and especially to the large ones.

2. Only one pair of forceps is required for the operation.

3. The artery should be seized obliquely, and not perpendicularly to its axis.

4. The torsion should be continued until the end seized by the forceps is detached.

5. It is useless to limit the torsion; it confines itself to the portion seized, or, at most, to one or two centimetres beyond this.

6. Atheroma is no counter-indication to torsion.

7. Torsion favors immediate union.

8. Torsion prevents primary hemorrhage as well as the ligature does.

9. Torsion presents a better safeguard against secondary hæmorrhage than the ligature—*La France Médicale*, March 25.

Aquapuncture.—Mr. R. Clemens Lucas calls attention to a number of cases illustrative of the relief derived from this treatment. Dr. Lélut unwittingly employed this simple expedient. His servant had by accident overturned a bottle containing morphia in solution; and, wishing to conceal her misfortune, refilled the bottle with water. The next day Dr. Lélut employed the liquid as a subcutaneous injection for a patient suffering from sciatica, in whose case he had previously injected morphia. The patient was relieved, and the pain disappeared without the nausea that had been excited on former occasions. After finding that the bottle only contained pure water, he repeated the experiment on other patients, and found that it invariably gave them relief, without inducing the unpleasant nausea caused by morphia. As to the manner of injection and the quantity of fluid to be introduced, Dr. Dieulafoy recommends that eight or ten drops of water be injected at the seat of greatest pain, repeated ten or fifteen times at one sitting if necessary. Dr. Lafitte says that he injects two grammes, and then waits a couple of minutes; and, if the pain be not relieved, then injects two grammes more.—*The Lancet*, March 4, 1876.

Meningitis and Ergot.—Dr. Sumrall writes us that he has come to the conclusion that deaths produced by compressed air are not caused by super-oxydation of the blood, but by meningitis. Immediately after the removal of pressure, in such cases, the vascular system dilates to its utmost, though the intercranio-spinal portion of it cannot, from its situation, dilate proportionately. The result is that this latter current is slowed, while that in the arteries and veins of the rest of the system is increased.

The result of this slowing is meningitis, and the rational treatment consists in restoring the proportionate calibres of the vessels. This may be accomplished by ergot. Of five cases of meningitis treated by other methods all died, while of seven who took ergot all recovered. His diagnosis in such cases was: Vascular dilatation, the result of a neurosis. The fluid extract was the form used, and it was given in drachm doses, repeated at suitable intervals.

Convulsions Arrested by the Sinistro-Lateral Posture.—Dr. F. J. Brown has seen two cases of convulsions arrested by turning the patient over upon the left side. One patient, a man, with Bright's disease, had uræmic convulsions, which ceased instantly after he had been turned upon the left side. Another man who had been seized with unilateral convulsions, was relieved in fifteen seconds after turning upon the left side. Dr. Brown's theory is, that this posture is in some way beneficial by favoring the heart's action.—*The Practitioner*, April, 1876.

Unusually High Temperature in a Puerperal Patient.—Dr. S. W. Torrey reports a case of this kind occurring in a primipara, who was delivered naturally of a healthy infant. For two days after confinement her condition was normal, the temperature being 99°. On the third day, she was found restless and with tender breasts. She had not slept the previous night, owing to the severe pains from prolapsed piles. Pulse 106, respiration natural, tongue moist, with temperature under tongue at the end of three minutes of 108°, and at the end of five minutes 108.5°. A mass of piles were found protruding from the anus; they were not inflamed, and were returned by gentle manipulation. There was neither nausea, pain in the abdomen, nor any sensitiveness over the uterus upon pressure. Ten drops of veratrum viride, and ten grains of Dover's powder were administered. The next morning the temperature was 100°, the milk flow was established, and there were no symptoms of metritis or peritonitis. The doctor regards the unusual high temperature as due to the irritation of the piles, increased by the milk fever.—*Boston Medical and Surgical Journal*, April 20, 1876.

Treatment of Arthrepsy.—M. Parrot has recently devoted a series of lectures to this disease of infants which has its origin in the digestive canal, and leads to a profound disturbance of nutrition. The symptoms are, in the first stage, altered fecal discharges, great thirst, and, despite the frequence of nursing, diminished absorption of milk. In the second stage, the passages become more and more unhealthy, and vomiting sets in with thirst, buccal ulcerations, diminished appetite, emaciation, and loss of strength. In the third stage, the child is past hope. It can only drink from a spoon, the vomiting is more frequent, the respiration difficult, the temperature lowered, the skin wrinkled, the aspect aged, and the flesh has a peculiar tallow feel. Rigidity and immobility of the limbs set in, and finally coma, or sometimes convulsions, precede death.

In the treatment of this disease, if any artificial nourishment be required, Mr. Parrot prefers cows' milk, pure and undiluted, which he gives in regulated quantities. After the sixth month rice or arrowroot preparations may be added. When diarrhœa and cough or coryza are present, the amount of milk given at each nursing is diminished, and heat and gentle rubefacients to be applied to the abdomen. If the diarrhœa persists, two grains of bismuth subnitrate are given in syrup of quinces six or eight times a day before nursing, lime-water being added if the discharges are green. When fever is present with a coated tongue, it is good to begin with an emetic; and when the discharges are mucous, a purgative is advisable. When the arthrepsy is acute and the condition of the patient becomes grave, three or four drops of cognac in eau sucrée, and a teaspoonful of bouillon, both iced, are given alternately every ten or fifteen minutes, and a hot mustard bath is ordered twice or three times day, followed by frictions, and the body is then wrapped in wool. If improvement sets in, these measures are less frequently used, and a gradual return to a milk diet is made.

In the more chronic forms of the disease, the stimulation must be less active; frictions are to be substituted for baths, milk to be given with a spoon; and six times a day, after feeding, a half teaspoonful of elixir of pepsine, which at the same time aids the digestion of the milk and is a stimulant to the stomach, administered.—*Journal de Méd. et de Chir.*, April, 1876.

The New Jersey Pharmaceutical Association held its regular annual meeting at New Brunswick, N. J., on May 17.

The New York Academy of Sciences propose to form field parties for scientific excursions into the suburbs.

The mortality rate of this city has very sensibly decreased within the last six weeks.

THE ENGLISH DEBATE UPON THE PATHOLOGY OF SYPHILIS.

II.

HAVING in our last issue given a general outline of the opening paper of Mr. Hutchinson upon the Pathology of Syphilis, before the Pathological Society of London, we shall now give briefly the main arguments of the various speakers. The discussion was commenced by Mr. Henry Lee, who favored his audience with one of his choice specimens of clouded argument, expressed in sentences almost, if not wholly, unintelligible. He did not agree with Mr. Hutchinson that gummata are sequelæ, and regarded them as due to blood disease, but he offered no facts. We commend to our readers the half of his speech, in which we presume, still we are not certain, that he was speaking of the differences between the two forms of venereal sore, as one of the best examples of turgid thought and involved language with which we are familiar in medical literature. Dr. Drysdale alluded, in a general way, to the doctrine of dualism, and expressed his own conviction of its truth, as shown by the differences in the two forms of venereal sore. He thought that Mr. Hutchinson was wrong in regarding it as dead, seeing that it is generally accepted on the continent. He regarded gummata as tertiary lesions, and caused by a blood state. He further stated the interesting fact that the keratitis of hereditary syphilis, described by Hutchinson, was looked upon as caused by scrofula by Fournier and Verneuil, who had informed him that they seldom saw it in France. In his practice, he had met with cases showing visceral affections in the secondary period of syphilis. It is evident that the formal opening of the debate devolved upon Sir James Paget, who was the first speaker at the second meeting. We can only express our surprise and regret at this performance of this eminent man, as his speech was long and turgid, and in many particulars his comparisons were flimsy and badly established. He looks upon syphilis as a specific fever due to blood disease, which is persistent, but diminishes in intensity by age. He thinks that the symmetrical distribution of lesions is always expressive of a blood state as cause; and that as the condition wanes, the expressions thereof become unsymmetrical. According to this view, gummata are not simply sequelæ. The similes offered by Sir James as existing between the sequelæ of syphilis and those of ague and typhoid fever are simply absurd, and show that he has not studied this question with his usual profundity. He is likewise weak in his effort to bolster up the view of Mr. Hutchinson, that tertiary lesions may be due to local morbid impress left by the earlier processes of the secondary period, as his comparison between them and the lesions, such as leech-bites and lividity of the arm, which he personally experienced, are entirely without foundation. Sir James applied leeches to his sprained wrist, which left scars. While well, these scars showed no abnormality, but when ill health supervened they became inflamed and ulcerated. In this case, there was simply a tissue debility, not due to a pre-existent morbid poison in the blood, as in the case of tertiary syphilitic lesions, which was aggravated by a lowered condition of the general nutrition, and nothing else. The only really valuable remarks of Sir James were those upon the relation of syphilis to gout, tuberculosis, and scrofula. He stated here, as elsewhere, that syphilis may predispose a subject to tuberculosis, and modify and complicate gout and scrofula. He thinks that the soil in which syphilitic poison is sown, or rather the peculiarities of constitution, tend to cause the varying appearances of the lesions; and while he admits but one virus as producing syphilis, he does not appear to make a distinction between the two varieties of sore. The remarks of Dr. Wilks are, on the whole, more unsatisfactory than those of the previous speaker, a fact which is surprising when it is remembered that he has been one of the foremost investigators in England into the nature of visceral syphilis. His speech was also very long, and too general in character. He truly remarked that there is no disease like syphilis in our nosology, but that it is a counterpart of other febrile diseases. He utterly rejects the terms secondary, tertiary, and quarternary as applied to syphilitic lesions, but unfortunately does not offer any clearer division. He fully admits the occurrence of visceral lesions in the secondary period, as he has seen such, and asks for more observations on the subject. He calls attention to a fact, not generally stated as being observed by himself, that frequently, when in syphilis the viscera are quite early affected, the outward manifestations of the disease are very insignificant, in comparison, and *vice versâ*. He also had observed that the infiltrations of syphilis did not, as a rule, suppurate, and that often, even when they had softened and fluctuation was felt, complete absorption might ensue. He endeavored in a labored argument, to draw a clear analogy between

syphilis and small-pox, but really did not add one idea to our stock of knowledge. He concludes his remarks, which occupy four closely and finely printed columns of the *British Medical Journal*, with the statement that, to his mind, the lesions of syphilis and scrofula were distinct and readily recognisable the one from the other. The remarks of Dr. Hilton Fagge were noticeable for their comparative brevity, a quality in general foreign to the discussion under consideration. He alluded to the point overlooked by Mr. Hutchinson, namely, the relation of syphilis to amyloid or lardaceous degeneration. According to Dr. Fagge, syphilis and prolonged suppuration are the only causes of this condition, and so strong is his opinion upon this point that he states that if at post-mortem he finds it without evidences of suppuration, he is confident that the patient was syphilitic. He evidently thinks that syphilis has no specific action in producing this degeneration, but that it is caused by the debilitating influence of the disease upon the general nutrition. He thinks that the lesions of the lungs in syphilities are caused in the same way, and that they are due to diffuse inflammatory changes, rather than to a definite or specific morbid growth. He holds the view that syphilitic eruptions are specific and readily recognizable, and that simple eruptions may exist on the skin of syphilitic subjects without being modified or losing their essential characteristics, even when the patient is subjected to anti-syphilitic treatment. Mr. Berkeley Hill's remarks were general in character, and fortunately not prolix. He thinks syphilis is a blood disease from first to last, and transmissible even in the later stages to the offspring. He further lays stress on the fact that children who have inherited syphilis from parents afflicted with tertiary or late syphilis, may communicate the disease to others, such as their nurses, in its most active and typical form, as being a powerfully affirmative argument. The fact that late lesions require for their cure anti-syphilitic remedies, is regarded by him as being proof that they are similar in nature to the earlier ones, which are undoubtedly due to a blood state. He thinks that Mr. Hutchinson attaches too much importance to the significance of symmetry of distribution of eruptions, and that in syphilis they are generally less symmetrical than in the other more acute diseases. He says the body generally is covered with an eruption in the early stages; this is succeeded by a more circumscribed rash; and lastly, this fades away until there may be one, two, or three patches on either side of the body. This statement, which is based on observation, really places the matter in a simple and intelligible form; it is really the practical illustration of the question of abundance alluded to by Mr. Hutchinson, but by him explained, as we know, in another way. Mr. Hill expressed himself quite clearly as to the variations in the type of the disease. He fully endorsed Sir James Paget's view, that the soil in which the virus is implanted is mainly the determining cause of the course of the disease; but added that perhaps the source of the contagion might also exert an influence. Thus he was disposed to think that the disease might be severer in its course when derived from a person in whom it was in an active form, and lighter when the contagion was waning in intensity. He did not accept the dictum of the orator that dualism is dead. Mr. Hill was followed by Mr. De Meric, whose remarks were terse and pointed. Without entering into a consideration of the doctrine of dualism, he asserted his belief that it was well founded. As to the analogy between syphilis and the specific fevers, he thought it perfectly correct with certain modifications as to variola only, and hinted that as regards the others, it was somewhat forced. In his experience phagedena was an exceptional occurrence, rather than the usual one; and he did not go as far as Mr. Hutchinson in saying that it was always due to syphilis. He adhered to the division into the stages, or periods, which are generally recognized; and hinted that Mr. Hutchinson had not simplified the matter by considering the disease as having but one stage and sequelæ. He thought that the symmetry spoken of by the orator did not exist as widely as it was claimed it did; and that it was impossible to place, as the latter wished to do, every lesion in mathematical order. Tertiary lesions showed a decline in the disease, hence they were the results of a blood state. He differed with Sir James Paget as to the simile of the leech-bites. Although Mr. De Meric did not express himself distinctly, it is to be inferred from his remarks that he thinks that syphilis may predispose a patient to the development of struma, and that both conditions give rise to different and recognizable lesions. We shall consider the views of other speakers, and the reply of Mr. Hutchinson in our next issue.

THE AMERICAN MEDICAL ASSOCIATION AND THE INTERNATIONAL MEDICAL CONGRESS.

In a few days the meeting of the American Medical Association will be held in Philadelphia, and in a few months that of the International Medical Congress. Be this order of exercises the result of chance or of prevision it is quite fortunate, since it gives to the former society the time to prepare its action on the latter, an action which will, in a measure, serve to settle the opinion of our transatlantic and transpacific confrères on our own professional merits. The apparently selfish aspect of the question is justifiable in view of the results to be obtained. Our success in the estimation of the foreigners will depend, not so much on the intrinsic value of the papers chosen to be read in Congress as the representative of American ability, as on the international direction which our leading men will, or will not, give to this medical-world conference.

The American physicians will not be judged so much on their lectures, as on their influence in the discussion of the questions most directly medico-international; just as the value of the next International Medical Congress will not reside in the individual value of the individual papers read on particular topics; but on the directness with which such papers and the discussions thereon will tend to increase the inter-communication, the inter-understanding, and the inter-coöperation of the physicians of all nations.

The task of elaborating this idea, and of bringing it into execution in the next congress with due authority and force, seems to devolve upon the American Medical Association, in virtue of its position, and by the uncontestable right which priority gives. For, by position, the American Medical Association is the only body here constituted to speak and to act in the name of the profession at large; whilst by its antecedents it has acquired the right to continue an action which it has initiated. It must be remembered that the American Medical Association sent abroad the first delegates who, in 1873 and 1874, invited the British Medical Association, and the French Association for the Advancement of Sciences, to coöperate in the project of establishing, among the physicians of all nations, a uniformity of plan for the study of disease by exact instruments, of scales, of records of observation, and a true common scientific language. It was also the American Medical Association which sent its delegates to Bruxelles in 1875, in order to introduce the same proposition before the International Medical Congress. There they found, in the section of ophthalmology, a proposition similar to their own, but restricted to a single point in the paper of Dr. Deltanche, "Upon the means of measuring the hearing and recording its degrees in a uniform manner in all countries." This limited application, in 1875, of the broad principle first enunciated by the delegate of the American Medical Association to the conferences of London, of Lyons, of Norwich and of Lille, constitutes the only foreign antecedent prior to the action which will be taken in the matter before the International Congress of 1876.

These precedents create, in favor of the American Medical Association, a right of pre-emption upon this great issue, which no medical organization at home nor scientific body abroad can contest; and which it would be more than a blunder to relinquish on the eve of the final success of International action.

Upon the strength of such antecedents, and by its own national and representative organization, the American Medical Association is entitled to be represented in the International Medical Congress by a strong delegation, especially charged to concert and to urge the adoption of the means of uniform observation so desirable in the scientific world.

Once this determination made, the chosen delegates will see the now rather vague ideal set before them take a substantial reality.

The first thing to command their attention will be the want of a common or uniform language among physicians. The idea of restoring the Latin to this, its former position, could not be mooted a moment, since Latin justly lost its position as international interpreter when it became the detective-agent of the Congregation of the Index for the destruction of the works of Galileo, Luther, Erasmus, Espinosa, etc. Besides, though strong in dialectics, it proves powerless to express the data of modern positivism.

On the other hand, if the modern languages are not found much better interpreters of positivism than the Latin, it has become apparent that the *universal language* so desirable for the interchange of scientific ideas is not so much to be looked for in the general adoption of *one* language, as in the agreement upon a technical uniformity of nomenclatures, of scales, forms of record, of observation, etc. The unity of mathematics throughout the western world, though founded at the time when the greatest diversity and confusion of language prevailed, was not restricted to the Arabic; but expressed itself in algebraic and arithmetic symbols, and became perforce the common language understood to this day by the mathematicians of all countries.

So will it be with the language of physicians. The Latin unity can no more express their advance, and each modern language proposed as a substitute would be subjected to the same ostracism by the others. But happily the language of positivism, expressed by figures, formulas and symbols, and exactly expressing the data obtained by the use of the instruments and methods of modern investigation, is ready to establish the uniformity and the unity of medical sciences. The difficulty of the enterprise does not reside in the complexity of the problem, but in our being unused to face it. Let us front it, and it is ours.

We know very well that nomenclatures differ all over the world. Simple drugs, pharmaceutic preparations, diseases even, and the very parts of our own body are known, or rather disguised, under different names. The status of a patient is seldom mathematically established from the first. One physician insists on some points, another on others. Instruments, scales, tables of record differ; hence most of the monographs commence—if they do not finish also—by descriptions from memory. This initial, or total absence of mathematical data, unfits the observations for becoming parts of the statistical elements of the numerical method. The differences between the scales and records used render the grouping and the comparison of cases impossible, and favor the predominance of imagination in diagnosis.

We desire to urge the matter of uniformity of system in observation and registration, because we believe that the general adoption of such a system

will be the only means of substantial progress, in fact one of the prime necessities of the present age.

As no body of our countrymen and confrères can have the authority to plead the cause of uniformity of observation before the coming congress equal to that of the American Medical Association, let its delegates be watchful that the international interests be not silenced in Philadelphia by simply interesting topics. On the contrary, let general, and, above all, international questions, be everywhere accorded the precedence. All the ideas advanced must present an interest commensurate with the radius of their auditorium. If this can be done it will be accounted a lasting honor for the American physicians to have taken before the other nations the initiative and the leading part in the restoration of the unity and uniformity of language in physic—the most momentous instrument of future progress.

It is written that the builders of the Tower of Babel dispersed when they ceased to understand each other. The lessons of their experience should not be lost to us. Already there is commencing a confusion of language, and a misinterpretation of ideas; these will increase with the progress of our work, and the sooner we agree upon some common understanding of necessary terms, the better. In this view let us hope that the opportunities of the meetings in Philadelphia may not be lost.

THE SHORT-TERM SYSTEM.

A WRITER in the *New York Times*, with the desire of informing the public concerning the present status of medical education in this country, denies the possibility of students receiving degrees from reputable medical colleges nine months after the commencement of their studies.

The writer says: "The burden of the complaint made by the RECORD against these outside schools is that they shorten the time of study. From an inquiry into the facts of the matter we learn that the requirements for graduation in the great majority of the schools are three years' study and attendance on two full courses of lectures. We also find that some of the schools referred to by the MEDICAL RECORD as being lax in this part of the law, are in reality very particular in compelling students to fulfil the requirements. The RECORD seems to charge that some of these schools permit students to graduate before completing the time of study required by law. We can find no evidence of the existence of any such irregularity. The editor of the RECORD will find it hard to persuade laymen to believe that it is all wrong for students to attend a Winter course of lectures and then a Summer course immediately after, while it is all right to attend a Summer course of lectures and then attend a Winter course after."

Certainly no one who pretends to know anything of the actual requirements of medical education will presume to claim that shortening the time of study is not a just and reasonable cause for complaint. We fully admit that the great majority of the schools insist upon two full courses of lectures and three years of study, but we are hardly willing, in view of facts before us, to believe that we are wrong in supposing that a student may get through in less time. The mere statement that this writer has not found any evidences of the possibility of the latter condition of things, proves nothing more than his culpable ignorance of facts and a general lack of information concerning his subject.

It seems hardly possible that the author of the article, pretending as he does to understand the principles advocated by the RECORD, should be so ignorant of what has lately appeared in its columns. As the result of a careful examination into the whole matter, he has come to the conclusion that all our efforts in connection with the discussion of the short-term system have been directed towards crushing out a few of the schools outside of New York City, in order to increase the size of some of the classes of some of the other overcrowded institutions. Preposterous and ridiculous as this assertion is, it is made with all the seriousness of one who wishes to be understood as speaking what he believes to be the truth. The very transparent attempt to pervert our meaning in regard to attendance upon Summer and Winter courses, is another evidence of his fitness for impartial criticism. It is hardly worthy of notice, except in connection with an ardent desire to create a false impression upon the outside public. We do not care how much our course may be criticised, but we have a right to object to wilful misrepresentation.

The student can attend as many courses of lectures as he pleases, the more the better, provided he gives himself time and opportunity for mental digestion. We care not when he attends them, nor where, whether in summer or winter colleges—but we object to the crowding of two full courses into one year, with the view of cutting short the term of study required by law. We have not the least doubt that this is often done, generally without the knowledge of the different faculties, it is true, but sometimes with their knowledge and connivance. Far from supposing that such things are impossible, we believe that half the so-called corruption in high places has not yet been exposed, and that the continued discussion of the short-term system may cause some still more astounding disclosures.

THE MEDICAL ASPECTS OF THE CENTENNIAL.

ONE of the attractive features of the great Exposition at Philadelphia, will be the important influence it must have in disseminating information upon special branches of science and art. Each department will be placed on an elevated position of æsthetic taste and cultivated skill, and will afford to students who desire

to embrace it, a rare opportunity for improvement and permanent benefit. The domain of Medicine occupies a comparatively modest niche in the grand display, but it presents numerous interesting points for description and discussion, which deserve careful study. Impressed with the desirability of affording our readers an insight into the various attractions here offered to the medical profession, we propose to publish frequent contributions from a special correspondent in Philadelphia, who will endeavor to give a faithful sketch of those portions of the Exposition, and of the salient features of current events in the Centennial City, which may especially interest medical men. The first letter of the series will appear in our next issue.

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, May 4th, 1876.

DR. S. S. PURPLE, PRESIDENT, IN THE CHAIR.

EPIDEMICS OF THE CENTURY AND LESSONS DERIVED FROM THEM.

DR. GOUVERNEUR M. SMITH read an interesting paper upon the above subject, in which he made a comprehensive survey of epidemics occurring between 1776 and 1876.

Brief reference was made to the philanthropic labors of Howard, who died in the latter part of the last century while in search of the cause and efficient remedy for the plague.

DR. ELIHU H. SMITH, who was nineteen years of age at the time of Howard's decease, was associate editor of the first medical periodical published in this country, and wrote the first paper which appeared in the journal. The title of his paper was, "The Plague of Athens," and in it can be found the remarkable statement that if local causes originated the plague at Athens, local causes might develop yellow fever in Philadelphia and New York. Dr. Smith died of yellow fever in 1799, the year following the publication of his paper.

DR. SMITH made a general reference to the sources and methods of transmitting disease, and the gradually increasing facilities for their discovery, both of which seemed to have been attendants upon advancing civilization. Following closely upon the discovery of new sources of disease, there have been found new prophylactics; and the discovery of those had been, in a good degree, commensurate with the demands for protection against the deleterious influence of newly discovered noxious agents. The doctor classified epidemic diseases under three heads, viz.: the contagious, the infectious, and the meteoracious. Under the first head were placed variola, measles, scarlatina, and varicella; under the second, typhus and typhoid fevers, malarial affections; under the third, influenza, typhoid, pneumonia, and erysipelas. Cholera and diphtheria, while contagious affections, seemed to a limited extent to be spread by meteoracious influences. There was an intimate relationship between the modes of prevalence of epidemic disorders. Some of the diseases at times being apparently diffused in two ways, *i. e.*, by specific germs, and by a somewhat wide-spread atmospherical diffusion of such germs. The present accurate manner of studying the subject would shortly enable the nosologist to make a more thoroughly scientific classification of epidemics than any hitherto attempted.

This classification, it was allowed, was not absolutely correct, because the processes and status of several of those disorders remained questionable. The classification had been retained for special reasons, and the doctor had placed cholera among the meteoracious diseases, but had accompanied the assignment with the following qualification. Under certain circumstances the atmosphere might become so impregnated with cholera poison that the disease might be communicated through that medium, but just how far cholera could be carried through the atmosphere had not been established. He believed it to be a contagious disease.

Of the specific nature of the poisons which have developed epidemic diseases there was entire ignorance; but, while our ignorance might be deplored in that respect, yet we might be assured and feel conscious, that through the medium of our increased knowledge of hygiene and prophylaxis, we should be able to disarm many of them of their destructive power.

Epidemics of small pox could be prevented, and measles and scarlatina, when they appeared, did not always become wide-spread, for two reasons: 1, because atmospherical conditions did not always favor their diffusion; and 2, when their diffusion was favored, increased vigor in adopting prophylactic measures was likely to check their spread.

Science had failed to find any specific cholera germs, and yet epidemics of cholera could be controlled by hygienic measures. By means of proper protective measures erysipelas and puerperal fever could be eradicated when once they had appeared.

Special reference was made to the study now in progress in relation to microscopic vegetable growths, and stress was laid upon the parasitic origin of several of the epidemics which had been considered.

Attention was directed to the fact that in war disease had slain more than the sword. In that connection, Dr. Smith referred to the lamentable loss of life which was caused by preventable diseases occurring in the Crimean army. Reference was also made to the labors of sanitarians and the adoption of sanitary measures during the late war in this country, together with the most gratifying results which were realized from labors for the protection of our soldiers from disease. The medical history of our war had shown that insalutary places could be made comparatively salutary, but such results had not come from the use of medicinal agents, so much as from the vigorous adoption of wholesome hygienic measures.

With regard to hospitals it had been demonstrated that light, air, speedy removal of refuse, and intermittent occupancy, were essentials. The doctor argued in favor of establishing local, state, and national boards of health.

The paper was closed by a reference to disinfectants, which were grouped under three heads:

1. Those which destroyed organisms;
2. Those which absorbed noxious elements;
3. Those which decomposed the poisonous compounds.

The paper was listened to with marked attention; and being open for discussion.

DR. ELISHA HARRIS spoke at some length concerning the benefits which had followed the study of epidemic diseases and the adoption of measures for their prevention. He regarded cholera as one of the most

controllable diseases with which the human family was afflicted, as it advanced only as transmitted by human carriers. The observance of certain rules of hygiene had excluded typhus from our armies, and the resources of prophylaxis had prevented the prevalence of typhoid fever in our country as it formerly had prevailed. He also referred to the report made by Klein, in which it was claimed that the nature of the poison that produced typhoid fever had been determined, and that it consisted of a microphytic growth, which attacked the follicles of Lieberkühn and Peyer's patches. By the simple process of growth, an erosion was produced, and upon the eroded surface the growth continued to increase with great rapidity.

Dr. J. C. Peters remarked that scarlatina was doubtless a filth disease. The plague of Athens had been proven to be an epidemic of malignant scarlatina developed by the filth incident to the extreme overcrowding of the city at the time of its prevalence. Dr. Peters spoke at some length upon the circumstances attending the introduction of yellow fever into New York, and believed that this fearful malady could be eradicated from Havana by cutting a canal which should properly drain that portion of the bay that received all the sewage of the city.

NEW YORK MEDICAL JOURNAL ASSOCIATION.

Stated Meeting, May 5th, 1876.

Dr. E. G. Loring, President, in the Chair.

ON THE MANAGEMENT OF THE PROLAPSED ARM IN TRANSVERSE PRESENTATIONS.

Although the principal object of the paper read by Dr. Frank P. Foster upon the above subject was to call attention to a particular method of management, yet he regarded it not unprofitable to give a general review of the doctrines which have been taught relating to the question under consideration. The doctor succeeded in giving a most complete and thorough analysis of the views entertained by all the more prominent obstetricians concerning the advantages and disadvantages of a prolapsed arm; concerning replacement and retropulsion; concerning traction and the use of the fillet; scarification and brachiotomy. The real point of interest in the paper, however, related to retropulsion of the arm, by which was meant, not merely replacement of the arm, but elevation of the entire cephalic pole of the child by pushing upwards in the line of the humerus. In the case related the above manœuvre was assisted by external manipulation. The doctor farther believed that when the shoulder was lifted, and with it the entire cephalic pole of the child, in the manner indicated, it then became a matter of indifference which foot was seized for the completion of version, in case the old operation should be found necessary. Another original recommendation made by the doctor was that in cases in which cephalic version was attempted, the arm be first replaced within the uterus, and then traction made upon it *in a lateral direction*, away from the head. Dr. Foster raised a general objection to the use of the fillet, on the ground that the unnecessary introduction of any substance into the cavity of the uterus, especially such fabrics as fillets were liable to be made of, was objectionable. The paper being open for discussion, Dr. Gillette remarked that he regarded it a matter of the greatest importance as to which foot was seized in performing the operation of version. He maintained that it was important to seize the foot opposite to the plane of the body presenting. In a pelvis of ordinary size, he believed that replacement of the prolapsed arm was not called for, unless the size of the accoucheur's arm rendered it necessary. He argued in favor of resorting to manual interference at once in case of prolapsed arm, not waiting for spontaneous version, which rarely if ever occured. He regarded the use of the fillet as a dangerous procedure, for it might be the cause of bringing the arm behind the head, instead of making it a reliable guide. He had never experienced any difficulty in delivering the arms when he had managed his cases in the following manner: the body of the child should be bent up under the pubis, and the posterior arm removed first, and then it should be bent back over the perineum, when the anterior arm could be liberated with ease.

Dr. Mundé related a case in which it was found impossible to reach the opposite leg of the child, and he was compelled to deliver by attaching a fillet to the limb that could be reached, pushing up with the other hand, and calling to his aid external manipulation by means of an assistant. The delivery was effected after about half an hour of hard work. The membranes had been ruptured for some time. He objected to the views of Dr. Gillette relating to the easy removal of the arms. His experience had been that, although the posterior arm should be first delivered, and ordinarily could be without difficulty, the anterior arm could not be so easily liberated. His plan of operation had been to first liberate the posterior arm, the body of the child having been pushed firmly against the pubis, and then to turn the body of the child completely around, when the anterior arm became the posterior and could be delivered in the same manner as the first. Replacement of the arm he regarded as unnecessary.

Dr. Gillette remarked that he could understand how difficulty might arise in delivering the arms in a primiparous case with contracted pelvis and large child, but that in a pelvis of ordinary size and cases of labor in general, he had experienced no difficulty whatever, when operating in the manner described. In all obstetric operations the woman should be anæsthetized, and her hips brought to the edge of the bed, for then the woman was in the most favorable position for the operation.

Dr. Munde remarked with reference to retropulsion, as described by Dr. Foster, that he could understand how it might be available in a relaxed uterus, and where the membranes had but recently ruptured.

[Dr. Foster's paper will be published in full in the *Journal of Obstetrics.*]

Quarantine Regulations.—The new regulations of the French Quarantine department are classed under the following heads:

Art. 1.—Cholera, yellow fever, and the plague are the only exotic contagious diseases, which in France demand the constant application of sanitary measures against the exports of the countries where these diseases prevail.

Art. 2.—Other dangerous, transmissible, and importable diseases, especially typhus and variola, may at any time be the object of exceptional precautions; but in this case the measures are only to be directed to the contaminated exports.

Art. 3.—Precautionary measures may always be adopted in the case of any vessel the hygienic conditions of which are considered dangerous, whatever may be the nature of its freight.

Correspondence.

SALICYLIC ACID IN RHEUMATISM.

To the Editor of The Medical Record.

Dear Sir:—My attention having been called in March last to the almost marvellous results accruing from the use of salicylic acid in the treatment of acute rheumatism, and believing in common with those who have recently recorded in your pages a successful trial of the same remedy in this hitherto unmanageable disease, that the accumulating experience of the profession with this treatment should be promptly reported, I am induced to send you the following brief history of a case wherein the asserted effects of the acid upon swollen and painful joints was displayed with great rapidity and persistence.

Mr. Edward Gordon, recently from Louisville, Ky., an assistant engineer of the D. and W. Railroad, applied to me at my office on the morning of April 25th for treatment of what he supposed was intermittent fever. He stated that a few days before his business called him out on the line of his road, and he was compelled for one night to sleep on the damp ground. The following day he had a chill succeeded by fever, which seemed to persist apparently unaffected by large doses of quinine which he had taken, and on this account he now applied for treatment. By my advice he went immediately to bed, and commenced the usual treatment of remittent fever, which prevails hereabout at this season of the year. The next morning, however, April 26th, he sent hurriedly for me to say that his ankle joints were swollen and exceedingly painful; that he had flying pains through his chest, and was apprehensive lest he was the subject of acute rheumatism, an attack of which he had had several years before, which had confined him to his room *for a period of three months*. He also stated that the disease seemed to be hereditary in his family, many members of which were predisposed to the development of an attack after the least amount of exposure to wet and cold. On examination, both ankle-joints, but more especially the left, were found tumefied, and so acutely sensitive to pressure that even the weight of the bedclothes was complained of. The intercostal muscles also were painful to pressure with the fingers. He had high fever, and was very restless and low-spirited.

The salicylic acid was now commenced in doses of seven grains, given in capsule, every hour, until four o'clock that evening, when the patient reported to me through a friend that he had a constant burning pain in his stomach, which had refused to retain more of the capsules, but that he was *almost entirely free of pain*. I called immediately, and found that he could move his joints with but a small degree of pain, and that the chest pains had also disappeared. He took ten grains of Dover's powder at bed time, and rested comparatively easy until four o'clock A.M. when the pain in the ankles (now more severe in the right joint) returned with all its original intensity. At seven o'clock A.M. the acid was again ordered, and being now better borne by the stomach was unremittingly given every hour up to six o'clock the same evening, when the joints were discovered to be *thoroughly painless, free from swelling, and could be moved in any direction without the slightest discomfort or inconvenience*. The capsules were continued the following morning, but only four doses were taken at intervals of two hours. The patient, by my instructions, remained in bed the 29th and 30th April, and without my consent made his appearance on the streets the next day, May 1st, but has not in consequence of his disobedience suffered any farther trouble from his malady. He called today to express his gratitude and great astonishment at the rapid and beneficial effects of salicylic acid, which he says is *the* remedy for acute rheumatism. May we not indulge the hope that in this opinion our patient is correct, and that as Stricker has intimated, "a real remedy for rheumatism has at last been found"

Truly yours,
Henry K. Leake, M.D.

Dallas, Texas, May 4, 1876.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from May 14th to May 20th, 1876.

Goddard, Chas. E., Surgeon. Assigned to duty as Post Surgeon at Fort McKavett, Tex. S. O. 85, Dept. of Texas, May 12, 1876.

Hubbard, V. B. Asst. Surgeon. Assigned to duty at Alcatraz Island, Cal. S. O. 45, Dept. of California, May 4, 1876.

DeWitt, C., Asst. Surgeon. Granted leave of absence for 21 days. S. O. 63, Dept. of the South, May 12, 1876.

Medical Items and News.

Contagious Diseases.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending May 20, 1876.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.

May 20.....	2	5	63	3	48	79	32

The Slaughter-House System in New York.—Assistant Sanitary Superintendent James presented a report regarding the condition of the slaughter-houses in this city. In concluding a brief summary of the nature and requirements of this branch of industry, he recommends "that all the slaughter-houses on the east side of the city, objectionable either from construction or location, be closed, and that the others be so altered and improved as to meet the requirements of the ordinance about to take effect."

Alumni of College of Physicians and Surgeons.—A meeting of the Board of Councillors of the Association will be held at No. 4 E. 37th st. this Saturday evening, May 27, at 8 o'clock.

The British Medical Association.—It has now been definitely settled, that the meeting of this Association, for this year, will be held at Sheffield, in Au-

gust next. Dr. De Bartolomé, of Sheffield, has been elected President in place of Sir J. Cordy Burrows, deceased.

Doses in Dispensing Bottles.—An Australian pharmacist indicates on his jars and bottles the maximum doses of the various drugs, in order to enable the dispenser to guard against any mistake by a prescriber.

Second-Hand Papers.—We take this opportunity of informing such gentlemen as are given to peddling their papers from one Society to the other, that none previously read or published will be accepted at the next meeting of the American Medical Association.

American Medical Association.—The next meeting of the American Medical Association will be held at Philadelphia, Tuesday, June 6, commencing at 11 A.M. As far as we can learn, no efforts have been made to obtain reduced rates of fare for members proposing to attend.

British Army Medical Department.—By the Royal warrant dated April 28th, 1876, the Army Medical Department of Great Britain has been reconstructed. A Surgeon-General ranks as Major-General; a Deputy Surgeon-General as Colonel; a Surgeon-Major as Major; and after twenty years service, full pay as Lieutenant-Colonel. A Surgeon ranks as Lieutenant for first six years of service, after which as Captain. Admission to the army is by public competition, and every candidate must possess two diplomas, one to practise medicine, and the other surgery.—A graduation of the army medical school at Netley is equivalent to public examination, and the graduate receives a commission as Surgeon for a period of ten years. The term of medical service is limited to ten years. Every year a number of surgeons not exceeding six, are selected by the Director-General of the Medical Department, to continue in service, and after serving twelve years more are promoted to the rank of Surgeon-Major.

The medical officers have a right to retire on half pay after twenty years' service. Surgeon-Majors are placed on the retired list at the age of 55 years, and Surgeons-General and Deputy Surgeons-General at the age of 60. At the completion of the first ten years of service, if no longer needed, the surgeon receives the sum of one thousand pounds. This constitutes the substance of the conditions of what is to be the short-service scheme.

Medical Schools in France.—A question of a correspondent concerning the number of the medical schools in France has called forth the following reply from the editor of the London *Lancet*.

"The medical schools at Paris and Montpellier have existed for centuries. They are termed Faculties of Medicine, and form part, with Faculties of Letters, Science, etc., of the great institution, comprising the whole country, known under the name of the 'University of France.' The third school (Nancy) is simply the Faculty of Medicine of Strasburg, transferred to Nancy since Alsace has fallen into the hands of the Germans. This Faculty of Nancy belongs, therefore, to the University of France; so also will the Faculties of Lyons and Bordeaux when fully organized. These two latter have but very recently been planned and sanctioned by the Government. As to Lille, it is quite a different matter. In the first place, it should be noticed that lately the French Legislature have allowed free Universities to be founded by the side of the University of France. A few have been started, principally under clerical influence. Among these must be reckoned Lille. But they have hitherto confined themselves to creating Faculties of Theology, of Law, etc., being unable, from circumstances, to add a Faculty of Medicine, which would require facilities for clinics, etc. The free Universities are not as yet empowered to grant degrees or diplomas.

The Exposure of Spiritualism.—A public séance was recently given at Chickering Hall, by Mr. W. Irving Bishop, for the purpose of exposing some of the impositions connected with spiritualism. His hands were bound behind him, and while seated on a chair were tied to a ring in a fixed upright. His head was secured to the same upright by a piece of muslin encircling his neck, and his feet were tied together. While thus secured he rang bells, played on the guitar, drove nails into a board, covered his head with an inverted pail, and performed behind a screen other astonishing feats. The screen being removed the same performances were repeated. The length of hand, flexibility of wrist and trunk, and the looseness of the skin of the wrist, enabled the performer to accomplish these wonders without a great deal of effort, and despite the tight bandages. Notwithstanding his limited opportunity for movement he could bring his hands sufficiently forward, by sliding the skin of the wrist, to manipulate with comparative ease. The performances were under the auspices of the St. John's Guild, and were well patronized. Dr. W. A. Hammond opened the entertainment with an address on the history of humbuggery. He traced it from the dark ages down to the present, giving illustrations of the gullibility of certain confiding individuals, and concluded with an allusion to the differences of opinion among neurologists concerning the value of the ophthalmoscope in the detection of brain disease.

Centennial Medical Congress.—The following gentlemen from abroad will be present at the meeting of the International Congress at Philadelphia in September next, in addition to those previously reported: Dr. Brown-Séquard of Paris, Dr. Robert Barnes of London, Mr. Henry Wilson, Dr. John Barker, and Mr. William Stokes, of Dublin, Drs. Morell Mackenzie, C. B. Radcliffe, and Mr. Wm. Adams, of London.

The Picton County Medical Society, of Nova Scotia, has appointed Drs. Wm. Mitchell, C. H. Munro, and Geo. Murray delegates to the Congress.

Enlargement of the Medical School of Paris.—An investigation of the project for the enlargement of the *Ecole de Médecine* has just been begun in the mairie of the sixth arrondissement; the investigation will last fifteen days. It is proposed to profit by the opening of the boulevard Saint Germain for the enlargement of this establishment, not only by taking in the ground bordering on the boulevard and what remains of the allée Larrey, but also by the acquisition of several neighboring lots.

Weekly Bulletin of the Meetings of Medical Societies.

Saturday, May 27.—New York Medical and Surgical Society.

Tuesday, May 30.—Yorkville Medical Association; adjourned meeting.

Thursday, June 1.—New York Academy of Medicine.

Friday, June 2.—New York Medical Journal Association.

Original Communications.

A UNIQUE CASE OF PROLAPSE OF BOTH VENTRICLES OF THE LARYNX—THEIR REMOVAL BY THE OPERATION OF THYROTOMY—CURE.

By GEORGE M. LEFFERTS, M.D.,

CLINICAL PROFESSOR OF LARYNGOSCOPY AND DISEASES OF THE THROAT, COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

THE following case is, as far as my knowledge extends, *an unicum;* for, although it is true that in laryngoscopic literature two cases of prolapse of the ventricle of the larynx are upon record,* the same condition, in a lesser degree, existing as in the case which I shall describe, in both of them; the lesion was only discovered upon post-mortem examination; and whether or no it had been present during the lifetime of the patient is unknown, the probabilities being, however, that it had not; as no symptoms were reported, which would certainly indicate that so serious a lesion of the larnygeal parts existed, and there being every reason to believe that the prolapse occurred, in both cases, *in articulo mortis.*† In my case, on the contrary, the rare opportunity was afforded of observing and studying the phenomena of this interesting pathological condition during life. I believe it to be, then, the first case in which such a chance has been afforded, and the first in which an operation has been undertaken having for its object the removal of both ventricles of the larynx. These points alluded to as ones of scientific interest, taken in connection with some others which will be detailed in the course of the clinical history, seem to me to render the case one of more than ordinary interest, and make it one which it is desirable to place upon record.

The history, as given by the patient, is as follows: Two years ago he very suddenly lost all use of his voice. Upon retiring one night it was perfectly normal; but the next morning, upon attempting to speak, he found himself completely aphonic. Repeated questionings can develop no cause for this sudden attack; no violence had been experienced, no injury received, nor had he made any unusual strain upon his vocal powers. His voice previously had been good, subject to occasional hoarseness, and he himself to the ordinary symptoms of a chronic catarrhal process of the pharyngo-laryngeal tract, due no doubt to his occupation, which demanded constant exposure. The cause, then, of this sudden onset of his aphonia I am from his history alone unable to determine. The voice having been entirely absent for some three weeks, at the end of that time began to improve slightly, and the patient was soon able to speak in a rough, hoarse whisper, and render himself intelligible to those about him. In this condition it has remained ever since. During the first part of his attack of aphonia, the respiration was only slightly interfered with; but one year later it had become progressively worse, and was then seriously embarassed—stridulous in character and preventing all active exertion—attacks of paroxysmal dyspnœa or laryngeal spasm have never been present; and the only inconveniences, besides the loss of voice and enforced quiet, of which the patient complained, were a constant sense of obstruction in the throat and more or less pain over the larynx, after prolonged efforts, necessarily powerful, at phonation. At this same time, one year after the commencement of his trouble, a small, rounded, hard tumor made its appearance over the upper part of the sternum, and two months later softened and discharged, leaving a ragged wound after the extrusion of considerable sloughy material, which occupied some two months in healing. No similar tumors have appeared elsewhere on his body; the inguinal glands have been enlarged, but no local sore preceded this enlargement, and a careful cross-examination throws no further light upon what may be an incomplete syphilitic history. As regards his present general condition it is good, and he has a clear hereditary history. Shortly after the wounds described above had healed over, a small growth was noticed to be forming over the left side and about the middle of the thyroid cartilage; it was painless, freely movable, and gradually increased in size. A second soon made its appearance immediately below the former, and as it increased approached and became attached to the first, so that the two together formed a large, irregular, nodular tumor, freely movable upon the wall of the thyroid cartilage. The tissues covering this mass have lately become adherent to it; it has approached the surface, and the overlying skin is reddened, somewhat œdematous and painful. Such then was the history given by our patient. Turning to the direct examination, the following results were obtained: External inspection shows that the left wing of the thyroid cartilage is overlaid by a hard, nodular tumor the size of a hen's egg, firmly attached to it, above and behind, together with the thyro-hyoid membrane; how much deeper the attachments run, manipulation cannot decide. This tumor, broad and adherent above and tapering to a point which is freely movable below, has displaced the thyroid cartilage markedly, so much so that its notch stands at least one inch to the right of the median line. The external appearances and the condition of the overlying tissues are as described above. With this one exception, there is no enlargement, either superficial or deep, of the lymphatics of the neck. The patient's respiration is labored and stridulous, both inspiration and expiration being equally affected; any exertion, and especially pressure over the tumor, which still further displaces the larynx, causes marked increase of the dyspnœa; deglutition is unaffected. His voice is lost; a rough whisper, only understood with difficulty, and itself lost after any prolonged attempts at phonation, being his only means of communication.

The examination of the larynx, the point, of course, of greater interest, could only be made after a prolonged training, rendered necessary by the unusual irritability of the patient's throat, together with an unfavorable anatomical configuration of the parts. A practicable degree of toleration being finally established, it was found that the normal lumen of the larynx was decreased more than one-half by the presence of an ovoid hard tumor, covered by a tense, red, and shining mucous membrane, which sprung from its left wall, immediately below the location of the false cord, and occupied entirely the ventricular orifice. The corresponding vocal cord, lying below the tumor, was unrecognizable, with the exception of a small portion at the lower and inner boundary of the tumor, which was seen only in phonation. The latter reaches,

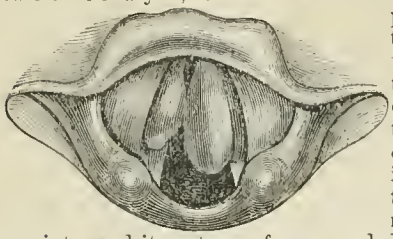
† Mackenzie: op. cit. p. 85.

as is seen in the drawing, from the anterior commissure of the larynx, to within a short distance of the posterior, and terminates in a wounded extremity, just over the location of the *processus vocalis;* its anterior extremity tapers more or less to a point; and its outer surface, rounded where it disappears beneath the false cord, presents a nearly flat surface on its inner side, looking towards the opposite wall of the larynx. During phonation this tumor remains quiescent, no movement being perceptible, and the respiratory process causes no change either in its form or position.



On the opposite side of the larynx, a most interesting condition of affairs existed, which may be shortly described as follows:—During quiet respiration, a thin pale fold of mucous membrane, broad and flat at its outer aspect, and more or less pointed at its inner, can be seen lying upon the superior surface of the vocal cord and projecting beyond its free edge, until it touches the tumor upon the opposite side of the larynx. Its insertion is immediately below the false cord and on a line with the ventricular orifice, the opening of which it fully occupies. The larynx being in a quiescent state—the true import of this condition—pathological though it evidently was, was not at once apparent, but the act of phonation effected immediate changes which plainly declared its character and rendered a diagnosis as to its nature, to be alluded to later on, easy.

As the right vocal cord, then, advances during the act towards the median line, finally passing it and adapting itself more or less closely in a crescentic form to the slightly convex surface of the growth upon the opposite side, the small fold of mucous membrane alluded to begins to *roll backwards* upon itself, the process beginning on its under side, until phonation being complete, and the vocal cord tense, the fold has *entirely disappeared* within the ventricle; and the orifice of the latter, heretofore not visible, appears to view, wider and larger than in a normal condition; the fold remains hidden while the cord remains tense, but as soon as the latter is relaxed and falls back into its position at the side of the larynx, it immediately reappears at the mouth of the ventricle and quickly rolls outwards into its former position. This interesting process may be repeated indefinitely, the same change always taking place in the relation of the parts during phonation, and was observed and studied many times, not only by myself, but by others to whom I had the pleasure of showing the case.

In addition to the above conditions, the general laryngeal mucous membrane presented the characteristic appearances of chronic catarrhal inflammation, that covering the arytenoid prominences being especially thickened and deeply congested. The left aryepiglottic fold and part of the membrane decking the corresponding arytenoid cartilage, were at the time of the first examination slightly œdematous.

A diagnosis as to the exact nature of the appearances I have described, was a matter not unattended by some hesitation on my part, my remarks having reference to the large, immovable tumor upon the left side of the larynx; that upon the right, after careful observation, presenting unmistakable evidences as to its character. Cystic growths,* springing from the ventricle, papillomata,† fibroids,‡ fibro-cellular, or mucous polypi,§ cancerous growths,‖ and hydatids,¶ have all been reported as occurring in this same location. The gross appearances of the tumor in my case was alone sufficient to eliminate the two first forms of neoplasm in the differential diagnosis. Its size, the absence of a pedicle, its form and color, served to distinguish it from a fibroid growth. Türck ** reports a case of mucous polypus of the left ventricle, which presents many points of similarity with the case under consideration; and I am by no means sure, judging from his description of it, that his case should not rather be considered as one of partial prolapse of the ventricle. Finally, it is a well-recognized fact that the primary cancerous nodule may occur in the larynx and in this location, and that in its early forms it presents no characteristic or diagnostic type, so that its early recognition by means of the laryngoscope is therefore much more difficult than in the benign new formations in the larynx. In this latter form of disease, glandular infiltration in the immediate neighborhood of the larynx, in the early as well as the late stages, is the rule, and this complication was marked in the case which I have described. I confess, therefore, that appearances led me to believe that the hard, immovable tumor upon the left side of the larynx was perhaps cancerous in its nature, although the possibility of its being a prolapsed ventricle was certainly entertained; and that the external nodulated mass, lying over the thyroid cartilage, was due to the involvement of some of the deep chain of cervical lymphatics, and that my diagnosis was not clearly settled until the removal of the tumor, and its microscopical examination proved it to be a *prolapsed ventricle*, infiltrated with cells and indurated by the deposition of abundant plastic material, the result of its strangulation and inflammation, subsequent to its extrusion into the laryngeal cavity.

Proceeding, therefore, with the idea that the tumor with which I had to deal was probably malignant in its nature, I selected the *extra-laryngeal* method of operating for its removal, for this and other reasons, prominent among which, were the fact that a prolonged training had not succeeded in reducing the great irritability of the patient's throat, and that the introduction of instruments into the larynx caused immediate and forcible spasm, rendering, therefore, a delicate and thorough operation impossible. Entire extirpation of the tumor, of course desirable were its nature malignant, would be impracticable through the mouth, owing to its peculiar location, while its size and density would render the operation, even if feasible, tedious, and the possibility of its removal *en masse* slight. The complication of the case by the presence of the prolapsed ventricle upon the opposite side of the larynx, offered an additional indication for the performance of an *extra-laryngeal* operation. It could not be removed by the natural passages, even in a well-trained case, without tearing away more or

less of the adjacent mucous membrane with it, and consequently exposing the patient to considerable danger, not only from the acute inflammatory reaction, with its sequelæ, which would follow, but also to that which would probably be caused by the subsequent cicatricial contraction.

Thyrotomy, on the other hand, presented a sure means which would permit of its removal by a clean incision, and would therefore obviate all of the above dangers. Finally, the indications for operative interference, determined by the state of the patient, were immediate. The operation was accordingly undertaken on April 7, 1875, with the assistance of my colleague Dr. R. F. Weir, as follows:—To permit of the removal of the external tumor, which lay over the left wing of the thyroid cartilage, a T shaped incision was made over the median line of the neck, and the tumor laid bare. It was found to be firm, dense, and nodular, with firm adhesions on its inner and upper borders, and over its base, extending not only to the upper left edge of the thyroid cartilage, but to the upper one-third of the left wing and well over the angle to the right. Above, they were attached to the thyro-hyoid membrane and the hyoid bone. The outer edge was free, and lay under the inner border of the sterno-mastoid muscles. The enucleation of the mass was proceeded with from within outwards, and accomplished as rapidly as the nature of the adhesions and the requisite careful dissection would allow. No connection was discovered between the intra- and extra-laryngeal growths, as was at one time thought possible might exist, and subsequent examination showed the removed mass to be made up of connective tissue, striped muscular fibres, small round or fusiform cells, packed irregularly together towards the edge of the sections, granular in their structure, and in some instances nucleated, adipose tissue and vessels. There was no traces of an epithelial structure, the mass being plainly inflammatory in its character. Whether or no it originated in a lymphatic gland was impossible to say (Dr. Mann). The original incision in the median line was now carried still further downwards towards the sternal notch, and the muscles and tissues overlying the trachea being pushed aside, and the isthmus of the thyroid body, downwards, a sufficient portion of the trachea was laid bare to permit of the introduction of a tracheotomy tube into an incision made from the fourth ring upwards to the cricoid cartilage. All spasmodic movements of the larynx and cough having subsided after the further administration of ether through the tracheal tube, and the parts being entirely at rest, the angle of thyroid cartilage was cleared by careful dissection of its overlying tissues, so that its edge might be plainly seen, and admit, after completion of the section and removal of the intra-laryngeal growths, of accurate coaptation, a result which I further endeavored to carry out by introducing threads through the wings of the thyroid, just above its notch, to serve later on as guides, when bringing them together. The thyroid cartilage was now divided in the median line, by a succession of short nicks or cuts, made with a small, strong, sharp-pointed knife, from above, below, until the crico-thyroid membrane was reached, carefully avoiding any penetration of the laryngeal mucous membrane with the knife, and thereby causing cough and spasmodic movements of the parts. The cartilage was readily divided above, but below was ossified at points, and gave some resistance. The section being complete, the edges of the incision were held slightly apart by means of small retractors, and the division of the mucous membrane undertaken. This part of the operation presented not a little difficulty, owing to the fact that the membrane was pushed before the knife, and not readily cut through, while spasm and cough further embarrassed a procedure which should have been very accurate, and was only made so by great care and frequent delays. I mention this fact particularly, because this method of division of the cartilage and membrane, introduced by Krishaber,* is theoretically good, and presents at first sight several advantages. My experience has, however, taught me the contrary, and I should hesitate to employ it in any subsequent operation. Separating the wings of the thyroid widely, by means of small hook retractors, still further space was found necessary, and was obtained by dividing the thyro-hyoid membrane upwards, and the crico-thyroid downwards, care being taken throughout the operation to preserve the cricoid cartilage intact.† A full view of the interior of the laryngeal cavity was now obtained, and it was seen to be about one-half filled by a broad, dense growth, situated upon the left wall immediately above the true cord. Its base, which was broad and thick, disappeared within the ventricle, the opening of which it fully occupied. The mass was hard to the touch, and could only be drawn slightly outwards from its seat. On the opposite side of the larynx, there protruded from the ventricle a rounded, pale fold of membrane which lay upon the corresponding cord. Pressure upon it returned it fully within the ventricle. Upon its anterior extremity, which was more rounded than its posterior, was a small linear elevation, terminating in a small protrusion, which undoubtedly represented the location of the *sacculus laryngis* described by Cruveilhier.

Spasmodic movements of the larynx being constant, and frequent efforts at deglutition causing a regurgitation of blood into the laryngeal cavity, obscuring the clear view necessary to a careful extirpation of the tumors, the parts were allowed to remain for a few moments at rest, the inhalation of ether being meanwhile proceeded with. I will say at once that, throughout the whole operation, these intervals for the purpose of anæsthetization were necessarily frequent, and as soon as the patient became quiet, an attempt was made to keep the larynx clear of blood and mucus by passing a small sponge, secured by a thread, above into the superior parts of the larynx and a second below into the ring of the cricoid. This procedure succeeded well.

The tumor upon the left side was now seized with forceps, drawn slightly outwards and cut away parallel with the ventricular orifice by means of curved scissors, and the wound subsequently cauterized. The same procedure was then adopted with the prolapsed membrane of the ventricle upon the opposite side of the larynx, and the excised portions at once placed in the hands of Dr. M. D. Mann, the able lecturer on microscopy at the College of Physicians and Surgeons, for examination and report. This has since been made; and, for the sake of clearness, I introduce his views as they have been communicated to me, at this point. He says: "The excised portion, taken from the right side of the larynx, over the ventricular orifice, was found to consist of loose connective tissue, surrounded by mucous membrane. The tissue was slightly infiltrated with small round cells, they

* (1) *Faits Cliniques de Laryngotomie.* Paris, 1869. (2) Heath, op. cit., p. 92.

† Hueter: *Handbuch der Allgemeinen und Speciellen Chirurgie.* Billroth, Pitha. Erlangen, 1872, p. 90.

being most numerous in the neighborhood of the vessels, a few striped muscular fibres were seen attached to the base of the mass; the vessels were large and numerous, well dilated, and filled with red globules. There was no disposition to proliferation on the part of the epithelial cells of the mucous membrane. The opposite tumor, taken from the left side of the larynx (see cut), presented essentially the same appearances, except that the small round cells were much more numerous, the tissue being literally packed with them. The position and appearance of the tumors substantiate the diagnosis of *prolapse of the laryngeal ventricles*, the primary cause being an inflammatory swelling and thickening of the submucous connective tissue, which, pushing the mucous membrane before it, protruded it through the ventricular orifices."

The edges of the thyroid cartilage were now brought together with care, and secured by four thread sutures, and the external wounds closed, the trachea tube being left in position. The hemorrhage during the various steps of the operation which I have detailed was not excessive, several small vessels were ligated and others twisted, being thus readily controlled. The general oozing of blood was more difficult to deal with, but sponging, and the application of ice occasionally, controlled it sufficiently to prevent its being a very serious annoyance.

The subsequent progress of the case may be summed up in a very few words; it, with the exception of a slight pneumonia, which developed itself on the third day after the operation, being in all respects satisfactory. On the fourteenth day a laryngoscopic examination was made, and the lumen of the larynx being found free, and respiration easy and uninterrupted, with the tracheal tube closed, it was corked, and removed two days later, when the wound was brought together with adhesive straps. On May 4th, 27 days from the date of the operation, the patient was discharged cured.

The main points of interest in the case remain now to be considered, viz., the results of the operation, and insomuch as the general question is still an open one, whether the operation of thyrotomy should "be earlier, more boldly and more readily resorted to" in the class of cases such as the one under consideration, or whether "it should be reserved for extreme cases," I regard each case added to the general fund of experience as having its value; and desire, therefore, to record the results carefully in the present one. As regards the special question of whether it was indicated in my particular case, to the exclusion of the intra-laryngeal methods, I leave the reader to decide; my belief, shared by others,* being that it was; and I have given my reasons therefor. Mackenzie† considers the results of the operation under four heads; and his classification being plain and to the point, I shall endeavor to follow it out in my summing up.

The rapid convalescence of my patient, his continued and present well-being, and the great relief afforded him by the operation, which certainly insures his future instead of detracting from his chances of life, answer conclusively the first proposition which is offered, the relation of the operation to the preservation of life. As regards the second, its relation to respiration, my answer is, that the operation afforded the patient a most marked relief, indeed effected a cure, for the stridor, laryngeal spasm, and dyspnœa have entirely disappeared; and his respiration is now uninterrupted, easy, and complete. The effect of the operation upon the voice, the third proposition, as regards its results, may also, I think, be answered favorably. I am well aware, as Mackenzie* states, "that the most elaborate efforts have been made by operators to give favorable descriptions of the voice after the operation," and I am therefore somewhat embarrassed in the choice of a term which will accurately describe its condition in my patient; but, having had an opportunity of examining several patients besides my own, upon whom the operation had been performed, and of hearing the result as regards the voice, I am perhaps in a position to intelligently judge of the result in my own case; and while I feel that my opinion also may be open to the suspicion of not being entirely impartial, I risk it, and desire to be clearly understood as stating the condition fairly, when I describe the voice as having undergone the most marked improvement, having become *full* and *loud*, and lacking only a certain slight, but perceptible element of clearness or tone, to be in all respects *perfect;* in short, was, I am convinced, as perfect a voice as is ever attained after the division of the vocal cords at their anterior commissure; for, granting that the approximation and adaptation of the halves of the thyroid cartilage after its division, was perfect and true, that the vocal cords lay therefore on the same plane and were intact in their continuity, still at the commissure, the point of their division, more or less plastic exudation must take place during the reparative process, and will interfere either by interposing as a mechanical obstacle to the perfect closure of the glottis at this point, or else by so thickening the cords and their free edges, that perfect vibration cannot, *at least for a time*, be secured. This condition, then, which was plainly to be seen by means of the laryngoscopic mirror in my case, and which was absolutely *the only trace* of the previous operation, perceptible in the larynx, was I believe the cause of this lack of perfect clearness of voice, which I have endeavored to describe; and this is proved by the fact, that during the time that the patient remained under my observation (some months) the voice *steadily improved*. It may be asked, did not the removal of the ventricles of the larynx influence the voice-sounds, and was not this perhaps the cause of the want of tone? This question I am not entirely prepared to deny, and indeed it is a most interesting one; and an opportunity for its elucidation here presented to us for the first time, as far as I am aware, from clinical facts derived from observations on the living subject. If the function of the ventricle is, as claimed by some,† to give resonance to the voice, which I doubt; then, perhaps, the removal of both, in my case, was the cause, partial or complete, of the want of absolute clearness in the patient's voice, although the physical and direct cause which I have given was fully competent to account for it without employing this hypothesis. Two other effects, which would theoretically be produced upon the vocal cords by the removal of the laryngeal ventricles, present themselves to my mind: 1. A limitation of their adductive mobility;‡ and 2, a deprivation of more or less of their lubricating mucus,§ which would render them dry and hard, and destroy in part their fine vibrating qualities. That both of these suppositions are in accordance with

§ Gray: Anatomy, p. 708.

theories which have been advanced as to the function of the ventricles, we well know. Whether they had their effect in modifying my patient's voice, is, as I have said, an interesting question; but, as far as my observation goes, and I studied the case carefully, realizing the unusual opportunity which was afforded me, I could not see that the action of the vocal cords was in any way influenced by their removal; adduction and abduction were well performed and their mobility in no way apparently restricted, nor were the cords dryer than they should be. Whether the first theory advanced had its influence, I am unprepared to assert; and prefer to submit the whole matter, as I have stated it, for discussion, modestly hoping that perhaps the case may throw some light upon a disputed question, and call forth an expression of opinion from those who are much better able to discuss the subject than I am, especially within the limits of a restricted paper.

The fourth and last question as to the prospects of thyrotomy, in its relations to immunity from recurrence of the removed tumors, is answered in my case, by the nature of the laryngeal tumors, for the removal of which the operation was undertaken.

Finally, I venture to think that the deductions which may be drawn from the foregoing facts as given, permit me to fairly class my case of thyrotomy among the successful ones.

Reports of Hospitals.

BELLEVUE HOSPITAL.

Notes of Practice and Peculiarities of Treatment.

INFLAMMATION OF THE STERNO-CLEIDO-MASTOID MUSCLE.

The patient was a child two months old. At the time of her delivery, the doctor, it was said, was obliged to make pretty strong traction upon the left side of the neck. Three days subsequent to delivery, the mother noticed a small lump, which was evidently situated in the sterno-cleido-mastoid muscle, below and just back of the lobe of the ear. This lump had remained of about the same size up to the day of examination. There had been no heat or evidence of inflammatory action, as the mother thought, but by the use of the thermoscope it was determined that there was some elevation of temperature present in the lump. The swelling was not in the glands beneath the muscle, for it was evidently situated above them; nor was it connected with the parotid gland in any way. The diagnosis was rupture of some of the fibres of the sterno-cleido mastoid muscle, followed by some inflammatory action, plus some hemorrhage. Prognosis good. Treatment inactive. This condition is rather rare, and one concerning which little or nothing is said in books. So said the visiting physician.

ACUTE ARTICULAR RHEUMATISM—ICE TREATMENT.

Two cases were seen, which illustrated not only the benefit derived from this plan of treatment, but represented two classes of patients; namely, those in which the joint symptoms are accompanied by only slight constitutional disturbance; and those in which the constitutional disturbance becomes the leading feature.

The ice treatment was regarded as the one which afforded special benefit in those cases in which the joint symptoms are prominent, and the success of the treatment depends very much upon the thoroughness with which it is carried out. The object is to relieve pain; and this is done very effectually by the application of ice, if it is properly used. It should be powdered (snow answers equally as well), and placed in ice-bags made of rubber or oil silk, and these should surround the joints affected. If the ice is not powdered, the joint is apt to be only partially covered, hence the application is not thorough. Properly applied, it seems to be almost a specific against the pain of this affection. The ice-bags should remain around the joint for 36 or 48 hours, and then they may be removed, but should be reapplied as soon as the pain returns.

The patient should be kept in the house just as long as when under any other treatment; and the usual duration of the disease was from 14 to 21 days. While ice was used, no other treatment was given; and by its use the patients before us were very effectually relieved of pain, which is decidedly worth accomplishing in a rheumatic patient.

Another case was seen, in which was illustrated the opposite condition already mentioned; namely, one in which the constitutional symptoms were the prominent feature. There was high temperature, some delirium, and evidently some constitutional disturbance. In this case, the patient was placed in a bath, having a temperature of 80° or 90° F., kept in for ten minutes, and the bath was repeated in two hours with great benefit.

There was another case, the like of which every practitioner has seen, one in which the disease had lasted for a long time; the patient had become anæmic, and, although the joints were involved, they were not acutely so. The patient was being helped out of his difficulty, as many of this class of cases can be—not all, however—by the use of the following pill, taken three times a day.

℞. Strychninegr. $\frac{1}{30}$.
Quinine, sulph.gis. iij.
M.
Ft. pil.

FRACTURE OF EXTERNAL CONDYLE OF HUMERUS—EARLY PASSIVE MOTION.

Particular attention was drawn to the importance of early passive motion in cases of fracture involving joints or situated in close proximity to them. The case was one in which fracture of the external condyle of the humerus had occurred, and was of sixteen days' standing when passive motion was first employed. At first it consisted simply in flexing, extending, pronating, and supinating the forearm joint a trifle, and each of these movements was made only a single time. Early passive movements, very slight at first, but continued, was the principle taught.

To illustrate the importance of this principle and its faithful and long-continued application, it may be stated that this patient returned to the hospital about one month afterwards, with his forearm flexed at nearly a right angle with the arm, and the elbow joint nearly anchylosed. His occupation had not rendered complete flexion and extension necessary, passive motion had been neglected, and the result has been stated.

HEMIPLEGIA—INVOLUNTARY DISCHARGES FROM THE BOWELS—SALICYLIC ACID AS A DEODORIZER.

The case was one of right hemiplegia occurring on a woman æt. 45 years. She had a moderately good

family history, and her personal history was good, with the exception of occasional intemperance. She was suddenly attacked while riding in a street car, had no loss of consciousness, but simply found herself unable to get out of the car when she arrived at her point of destination. When admitted to the hospital there was slight aphasia. There were involuntary movements from the bowels; and for the relief of these, belladonna and electricity were employed. The belladonna is very serviceable for the relief of both involuntary discharges from the bowels and incontinence of urine. The chief item, however, for which this note was made was the use of salicylic acid to deodorize the fæces. In a few cases the use of the acid for this purpose has been attended with very satisfactory results, and the odor has passed away entirely with the gaseous escapes from the bowel, thus avoiding the excessive offence that attends a discharge of fæces in their natural condition.

POINT IN PHYSICAL DIAGNOSIS.

The point related to the location of the gall-bladder. In most books it is said to be situated just above the free border of the ribs, directly under a line drawn from the nipple to the umbilicus, or a line drawn nearly vertical from the nipple to the free border of the ribs.

The point made was that neither of these directions for determining the location of the gall-bladder was correct, but that it was situated just above the free border of the ribs, directly under a line drawn from the symphysis pubis to the inner border of the rounded outline of the head of the humerus.

HÆMATURIA, INTERMITTENT IN CHARACTER.

This case had been quite puzzling to all who had attempted a diagnosis, and the leading features were as follows:

A male patient, æt. about 55, had, since admission to the hospital in June, 1875, presented symptoms referable respectively to the heart, the lungs, the bladder, and the kidneys. His heart was slightly enlarged; that is, there was probably hypertrophy and dilatation of the left ventricle, and at the same time a loud systolic murmur was heard with its maximum intensity at the apex and conveyed to the left, indicating mitral regurgitation. The action of the heart, however, had always been regular, and, except for the physical examination, the cardiac disease would probably have escaped notice. With regard to the lungs, he had had occasional attacks of hæmoptysis, and during these attacks had coughed up considerable quantities of blood. There had been found dulness upon percussion, accompanied by coarse and fine râles over different portions of the chest, and sometimes bronchial breathing had been present over those affected portions. These physical signs had been intermittent. At no time, however, had they disappeared *entirely*. During those periods when the physical signs had been the most prominent, there had been a certain amount of febrile movement. The temperature had become elevated for several days, and that had been coincident with the more marked development of the physical signs mentioned. From this train of symptoms, it was believed that he suffered from occasional attacks of pneumonia; not the ordinary croupous pneumonia, but from that form of pneumonia which consists of a mere filling up of the air vesicles with hypertrophied pulmonary epithelium; in other words, the form which very frequently accompanies chronic heart disease. Each of these attacks, it seemed, had been attended with a certain amount of bronchitis; and it was believed that it was the bronchitis that gave rise to the elevation of temperature and the râles. It was the lung consolidation which gave rise to the dulness upon percussion. In addition to these symptoms, the patient had from time to time passed bloody urine. During his stay in the hospital he had at short intervals passed bloody urine a number of days in succession; sometimes in clots, sometimes mixed with the urine, and sometimes in considerable quantities. Between the attacks of passing blood by the urethra, the urine had been *entirely clear* until very recently; then, more than four months subsequent to his admission, considerable quantities of mucus had been discharged with it. When he had not been passing blood, there had not been any evidence whatever of bladder trouble. The prostate gland was not enlarged; no tumor had been detected in the bladder, nor calculus, nor was there any physical evidence of disease of the kidneys, and no tumor could be felt along the course of the ureter, nor in the regions of the kidney. How was the intermittent hæmaturia to be explained? It was regarded as part and parcel of the same pathological lesion which gave rise to the hæmoptysis; and that both depended upon the chronic valvular disease of the heart.

LEUCOCYTHÆMIA—SPLENIC VARIETY.

It was a well-marked case, for the spleen measured 16 in. in vertical and 12 in. in transverse diameter; there was no enlargement of abdominal or thoracic glands that could be detected; there was only a very slight enlargement of the glands in the groin, and the proportion of the white to the red blood-globules was about one to three or four.

Repeated examinations of the urine had been made, but no excess of *uric acid* had been detected. The patient at one time improved considerably while drinking beef blood.

PRODROMATA OF HEMIPLEGIA.

The following case gave rise to certain suggestions, which were noted as follows: A female patient, æt. 50, who was perfectly well three weeks ago, first noticed that a brush fell out of her hand. She picked it up, and it fell from her hand a second time, and then she found that she was speechless. She took to her bed as soon as she became speechless, and in a short time the headache which had *preceded* the attack, passed off, and did not return. Vertigo preceded the headache. A mitral regurgitant murmur was present. Now what had caused the hemiplegia in this case? It was observed that cerebral embolism was almost always preceded by the lodgment of emboli in other organs: (1), the spleen, most commonly; (2), the kidney; and (3) the liver. The question to ask then was, Have you at any time been suddenly attacked with severe pain in either side, or in the back accompanied by trouble with the water? In this case the answer was in the negative; and that led to the consideration of the *prodromata* of *apoplectic hemiplegia*, or cerebral hemorrhage. The first predisposing cause was said to be endarteritis, which resulted in diminishing the calibre of the arteries; hence both functional and textural derangements occurred in the parts supplied by the arteries affected. In other words, there was degeneration of nerve tissue preceding the development of apoplexy. The results mentioned were:

First. There was loss of memory; especially memory of words.

Second. Sudden confusion of ideas; the person might be talking, for instance, and all at once be obliged to stop and think what he was about to say.

Third. Vertigo. If an elderly person suffered from vertigo, and it was associated with a foul tongue, it might depend upon stomach trouble; but vertigo with a clean tongue was regarded as a premonitory symptom of an apoplectic seizure.

Fourth. Wakefulness early in the morning. For instance, a person who had commonly slept well, began to awaken early; and especially apprehensive was that symptom, if it was accompanied by headache, which wore off after the person arose and began to exercise.

Fifth. Cramps in the calves of the legs. The visiting physician remarked that he had never seen a case of embolism that was preceded by that symptom.

Sixth. Numbness upon one side of the body. Now, to prevent the occurrence of apoplexy: First, remove the constipation commonly present. For that purpose, a favorite pill was the following:

℞ Ext. colocynth co..... ʒ i.
Ext. nucis vom..... grs. x.
Ext. belladonna..... grs. v.
Div. pil. No. xx.
S. One at night.

The compound licorice powder, consisting of senna, cream tartar, and pulverized licorice, was also recommended, in teaspoonful doses. For the endarteritis itself, bichloride of mercury was recommended in one-twentieth grain doses, until all the prodromata had passed away; and with that remedy, nitrate of silver in ¼ grain doses might be combined with advantage. In many of these cases, cod-liver oil might be indicated. Such was the plan marked out.

EXCISION OF THE SHOULDER-JOINT—RECOVERY, WITH ALMOST PERFECT MOTION.

The history of the case was rather interesting, and is outlined as follows: The man came into the hospital to obtain relief from what was supposed to be an abscess about the shoulder-joint. He had had his shoulder injured some time before his admission by the heel of a boot placed in the axilla, while efforts were made to reduce a supposed luxation. The tumor was opened and pus escaped, but with it came a rush of blood that required a vigorous use of cotton and persulphate of iron for its arrest. An aneurism had been opened. The shoulder-joint was subsequently excised, and about one inch of the shaft of the humerus removed. At the operation, it was found that the aneurism was connected with the posterior circumflex artery, and it was thought it probably commenced at the time the pressure was made on the axilla. Subsequently, inflammation about the sac had occurred, and when the opening was made to allow the escape of pus, the aneurismal sac was punctured. The motion of the arm was almost perfect, and the man stated that he could work as well with his right as with his left arm.

COLLES' FRACTURE.

The case presented one point of interest, at least, which was worthy of consideration. It was treated by position. The fore-arm was laid upon a piece of board, and swung in a sling, and then allowed to take its own natural course without interference on the part of the surgeon. The result was as good as that obtained by any special plan of treatment.

WALKING PNEUMONIA.

This case presented a few points of interest, and warranted a brief sketch of its history. A male patient, æt. 50 years, had been sick two weeks. He was seized with a chill which was followed by a fever and sweats, free expectoration of blood of a bright red color, and bright red blood was also discharged from the bowels.

Physical examination revealed a vesiculo-tympanitic percussion note at the upper portion of the chest, upon the left side in front, and dulness upon percussion below the spine of the scapula, upon the left side, together with bronchial breathing, broncophony, increased vocal fromitus, and sub-crepitant râles. At the time of the examination, the disease had probably been present ten or eleven days. The man was intemperate, and it was remarked that copious bronchial hemorrhage recurs not infrequently at the outset of a pneumonia, taking place in persons of such habit. The discharge of blood from the bowels having a bright red color at the same time, showed that there was present a general tendency to hemorrhage from the mucous membranes. The man felt well; had a pulse of 105, and a respiration only a trifle hurried. Pneumonia, it has been said, occurs more frequently at the apex than at the base of the lung in persons addicted to the use of alcohol. This case, therefore, was an exception to the stated rule.

SUBACUTE PLEURISY—VOCAL FROMITUS—ASPIRATION.

The history of the case is not necessary further than to state that ℥ xxxii of fluid were drawn out of the left pleural cavity, which placed the diagnosis beyond doubt. Before the fluid was withdrawn, however, vocal fromitus was *distinctly obtained over the fluid*, and indeed was more marked than it was after the fluid was withdrawn. This also was an exception to what has been regarded as a rule. Another feature in the case was the equal size, by exact measurement, of the right and left sides of the chest, although there was some bulging of the intercostal spaces upon the left side. There was probably some enlargement of the left side, because the man was right-handed; and the left chest, quite likely, was naturally somewhat smaller than the right. The aspirator was used, although there were no urgent symptoms present. It was believed that the patient would do much better with the fluid removed, than to permit it to remain, and trust to the absorbents for its removal.

Progress of Medical Science.

A STRANGE AFFECTION OF THE HAND.—M. Després recently exhibited to the *Académie de Médicine* a patient who presented the following appearances: His forearm and hand were of a bright red color and exhibited several ulcerations, some covered with granulations and some having a grayish floor. The index, ring, and little fingers were almost entirely destroyed. There was no swelling of the parts bordering on the ulceration; the parts of the fingers left were very red, wine-colored, thin, and the integuments were indurated; close to the ulcerated parts the bones were laid bare in spots by the sloughing of the soft parts. The patient complained of acute lancinating pains in the forearm, hand, and fingers, increased by exposure of the parts to the air. The disease had commenced seven or eight years before, with ulcerations of the forearm, which developed successively and left a

number of white irregular cicatrices that are still visible. The patient had some scrofulous manifestations in his infancy, but his health had been good up to the outset of this disease.

M. Després denominated the affection lupus of the hand. M. Duvergie considered it an instance of a form of leprosy that is endemic in France. M. Hillairet denied the existence of a leprosy originating in France, and held this to be an instance of an affection described under the name of symmetrical gangrene of the extremities. M. Hardy agreed with M. Hillairet, and drew attention to the relations existing between leprosy, symmetrical gangrene, and scleroderma, all of which appear to depend on a lesion of the nerves presiding over nutrition. The discussion ended without having cleared up the question.—*Journal de Méd. et de Chir.*, April, 1876.

Carnivorous Plants.—*The Révue des Deux Mondes* for February contains an excellent article on this subject by M. Planchon. The true carnivorous plants seize and retain a living prey, digest and dissolve it by means of an acid glandular secretion, and finally absorb, and are nourished by the products of this digestion. The most important of these plants is the drosera, the upper surface of the leaf of which is covered with hairs or tentacles, moistened with a viscid, acid, glandular secretion. When an insect lights on one of these leaves it is seized and imprisoned by the tentacles, the leaf then curves on itself and encloses it, and the process of digestion begins; this terminated and absorption completed, the leaf flattens out again, and is ready for new victims. If small pieces of meat or of hard-boiled white of egg be placed on a leaf, they are seized in the same way, and may be seen gradually softening and becoming diffluent and transparent under the action of the acid secretion of the plant, which will also attack cartilage and even the enamel of the teeth. The absorption of the products of this digestion is shown by the dryness of the glands of the tentacles towards the end of digestion, and by the changes of color in the protoplasm of the cells.

The drosera muscipula, and the pinquicula present analogous phenomena, with some minor differences, as do also the nepenthes distillatoria, and several varieties of the sarracenia, and it is probable that further research will add many other varieties of plants to the list of carnivora.—*Lyon Médical*, April 9.

Confervæ in Solution for Hypodermic Injections.—M. Limousin, who has been experimenting with the substances that are said to prevent the formation of the confervæ, recently presented to the *Société de Thérapeutique* a solution containing four grains of hydrochlorate of morphia, and one twenty-fifth of a grain of salicylic acid, which he had kept for two months, and which did not show a trace of confervæ. In the course of his investigations he had obtained a salicylate of morphia, but as it was only soluble in the proportion of 1 to 150, it was useless for hypodermic use. A salicylate of quinine was still more insoluble. M. Beaumetz obtains excellent results by employing the distilled water of cherry-laurel.—*Le Mouvement Médical*, April 8.

Pathology and Treatment of Angina Pectoris.—Angina pectoris is generally considered to be a neurosis of the cardiac plexus. This, however, Professor Sée denies, because the sympathetic is not a sensory nerve. He considers it an affection of the pneumogastric alone, the only sensory nerve that enters into the formation of the cardiac plexus, and maintains that it is due primarily to anæmia of the heart. The mechanism of its production he explains as follows: When, in consequence of some organic lesion, the myocardium receives less blood than normal, the terminal branches of the pneumogastric contained in it receive less also, and it is a well-known fact that pain and numbness are the immediate consequences of anæmia of a nerve—hence the anxiety and the substernal pain. This pain produces a reflex irritation of the motor branches of the spinal-accessory nerve, which is the real moderator of the heart's action, hence the heart's action is at first less frequent, becoming accelerated and irregular only when the excitation of the moderator nerve gives place to exhaustion and paralysis. This excitation may even be sufficient to cause a stoppage of the heart's action. The radiation of the pain into the left arm, etc., is explained by the transmission of the initial excitation of the intracardiac filaments of the pneumogastric to other neighboring nerves. The excitation is transmitted to the nerve centres, and thence reflected at once by eccentric or secondary irradiation to other sensory nerves. With these radiated pains, veritable reflex motor disturbances may be associated; for instance, trismus or constriction of the œsophagus.

Professor Sée also claims that this explanation applies equally well to the so-called cases of primary angina pectoris, which is generally supposed to be a simple neurosis, totally independent of any cardiac lesion, though it may end fatally. These cases are principally met with in topers, smokers, the gouty, the hysterical, and in hypochondriacs. One of the first symptoms of alcoholism is endarteritis, and no one claims that the coronary arteries are exempt from this lesion. Smokers are said to be very subject to angina pectoris, but this is the case only with those who use tobacco excessively, and in whom it has already lessened the appetite and weakened the digestive powers. An intermittent and irregular pulse is the first symptom of this excessive use of tobacco, and this is followed by a tetaniform contraction of the vessels. Is it irrational to suppose a similar contraction of the coronary arteries, and consequent ischæmia of the heart? Cardiac lesions, especially of the myocardium and the coronary arteries, are the rule, not the exception in old gouty patients, hence angina pectoris cannot be primary in them. Finally, vaso-motor disturbances are well known to be of frequent occurrence in cases of hysteria and hypochondriasis, and spasm of the coronary arteries will produce ischæmia of the heart just as well as atheroma. Angina pectoris is therefore held to depend on a similar anæmia.

The indications for treatment are promptly to relieve the pain, to regulate the circulation, and to facilitate the respiration. Hypodermic injections of morphine are the most reliable means of treatment. Chloral hydrate is second only to morphine. It produces sleep more promptly, relieves pain better, and facilitates respiration, but it has hardly any effect on the circulation. It seems to be absorbed more rapidly when given by the rectum than by the mouth. Chloroform is too dangerous to be used. Nitrite of amyl, a drug little used as yet in France, produces dilatation of the vessels, but has no sedative effect, and hence fulfils the indications only in part. Hypodermic injections of atropine are dangerous, especially in children. The antispasmodics proper are useless. Electrization of the sympathetic is out of the question, and of the pneumogastric, though vaunted by some, is dangerous. In the intervals of the attacks, we must rely on digitalis, bromide of potassium, and good hygiene. —*La France Médicale*, April 5 and 8.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

New York, June 3, 1876.

QUESTIONS FOR THE AMERICAN MEDICAL ASSOCIATION.

Several topics, of more or less interest, will doubtless engage the attention of the American Medical Association at its next meeting. We have already suggested, in our last number, what one of these should be, as influencing the legislation of the Medical Congress upon a matter which has a truly national importance. It is not necessary to do more than remind our readers of the arguments in favor of the proposed system of uniformity in clinical observation, to give us the excuse for urging its hearty recommendation by a suitable committee from this Association. There are, however, other matters to which we wish to draw attention in view of the possibility of their being brought up for discussion. One of these has prospective discordancy about it which we do not like, and which, for the harmony of the meeting, we would fain hope would not be brought up at all; we refer to the homœopathic trouble at the University of Michigan. There is such a determination by some who have taken an active part in the discussion to spring the question upon the Association, that nothing but the greatest care will prevent a disgraceful exhibition of unreasonable temper and hot-headed partisanship. The latter will be the inevitable result of a free family talk over the merits of homœopathy. There are two sides to the Michigan University affair which deserve to be carefully considered before action is taken—to be thoroughly canvassed before a definite and impartial decision is rendered. As it is impossible in open meeting to go over the merits of the case in the detail necessary for a general understanding of the point at issue, the wiser course would be to refer the whole affair to a committee who should have the requisite time for learning all the facts of the case. In no other way can this question be settled to the satisfaction of the thinking men of the profession. We have enough confidence in the good sense of the majority of the members of the Association to believe that the course suggested will be the one promptly adopted, if attending circumstances make it necessary.

We cannot expect to escape the usual report on medical education, in one guise or another. We should not if we would. During the past year more than usual attention has been directed to many needed reforms in preliminary education, college standard, and graduating requirements. The Association has a by-law which provides that preliminary education shall be a condition for entering a medical college, and yet it is practically a dead letter. This, however, is not due to any shirking of responsibility in regard to the expression of an opinion or any lack of desire to enforce the necessary conditions. The real responsibility for the non-fulfilment of an implied promise rests upon the colleges themselves, showing a reprehensible apathy towards measures which the profession at large consider of the utmost importance.

The elevation of the college standard is another subject in which the Association has been deeply interested, and while it has accomplished much in the way of substantial progress in this particular, very much more remains to be done to encourage the faithful workers in the interests of this reform. While, however, it is zealous for progress, it must be watchful of any retrograde movement, of any attempt to shorten the prescribed term of study, such as is reported to have been made in some few of the Colleges. There have been so many ugly rumors connected with the management of these institutions, so many questionable practices of increasing the number of students, of which they are said to be responsible, that it now becomes the duty of the Association to examine testimony and be prepared to exert its authority in the punishment of such as are really proved to be guilty. Rest assured, of the support of the profession it has nothing to fear in the performance of its legitimate duty.

The requirements for graduation, although last in the list, are by no means of the least importance. Far from this being the case, their proper definition and the adoption of the proper regulations for their enforcement is the substantial and practical starting for the reform of the other evils now so inseparable from our present College system. A strict and impartial examination for graduation makes the fulfilment of the conditions of preliminary education, time of study and method of teaching, absolute necessities. We have repeatedly referred to the method of conducting these examinations by independent boards, and our readers are sufficiently familiar with the advanced ideas upon the subject. This matter of state board examinations has been so thoroughly discussed that the Association should be prepared to act upon some one of the suggestions which have been thrown out by

the different writers upon the subject, and which have the most reasonable claims for practical application.

The project for the formation of a National Health Board is one which has been urged by sanitarians for a long time, and it is gratifying to see that the Association is determined to use its influence in the direction calculated to do the most good. The interest which has been awakened is, we trust, not likely to grow lukewarm, and we anxiously look for a report of substantial progress in the work at the next session.

The army-rank question is another which will doubtless receive its annual ventilation of resolutionary endorsement, but the present prospect of forcing the conviction of its importance upon our legislators is not so promising as we might wish. Still, not discouraged at failures, it is the duty of the Association to continue to work and to make every effort to gain its end.

In conclusion, we have to say that the present organization of the Association is such as to leave no doubt of its efficiency of work in all its different departments, and we see no reason, under the administration of its distinguished president, why its coming deliberations may not be wise and temperate, and its influence for good be commensurate with its importance as the representative national medical organization of North America.

THE ENGLISH DEBATE ON THE PATHOLOGY OF SYPHILIS.

III.

In our last issue we had followed the debate on Syphilis before the Pathological Society of London to the end of the address of Dr. De Meric. We come now to consider those of others, beginning with Dr. Broadbent. This gentleman's remarks were, on the whole, valuable and pertinent, but rather too lengthy. He differed from Mr. Hutchinson in certain points as to the course of infantile syphilis. He had seen gummatous infiltrations into the tongue and skin in subjects of this disease, an occurrence, if not denied, yet considered very improbable by Mr. Hutchinson. He alluded to the fact referred to in the opening, that two subjects of congenital syphilis had died in consequence of granular kidney, which condition, by Mr. H., was thought to be due to the use of iodide of potassium. He had seen a case in which such a complication was observed, and being in doubt as to its causation, suggested that data bearing upon it should be produced. He alluded to the fact that the evidences of hereditary syphilis disappeared quite completely in time, and that subjects of the disease enjoyed average good health. He evidently leans to the opinion that when amyloid disease is found in early life it is due to this disease. Taking up then the question of the nature of gummata, he differed from some other speakers in thinking that those of syphilis are specific, and that those of the exanthemata are not so, citing thrombosis, necrosis, catarrh of the middle ear, and the parotid bubo of typhus, which may be due to other causes than the specific fevers. He cited the fact alluded to by Mr. Hill, that severe tertiary often followed mild secondary lesions as tending to show a specific character of the former. Strangely enough he pronounced himself as an advocate of the old theory, now renounced even by its former advocate, Mr. Hutchinson, that a woman could be infected by syphilis from a fœtus, and become more syphilitic by such pregnancy. He came to this conclusion from the observation of cases of nervous affections in mothers who confessed to have had syphilitic children, and by seeing the disease in a more intense form during and after each pregnancy. It is evident that he had not in these cases clearly traced out the regular course of the syphilis. The next speaker, Dr. Buzzard, as might be expected, touched chiefly upon the nervous phenomena of the disease, and briefly gave some interesting facts. He thinks that the frequency of occurrence of nervous troubles in secondary syphilis has been underrated. Of one hundred cases of brain syphilis cited by him the average age of the patients was thirty-five. In eighty three cases the date of infection was ascertained, the nervous phenomena supervening after five years in fifty-six, and within that period in twenty-seven. In short, in one-third of the cases the nervous system was involved within five years of infection. The supervention of nervous trouble in the eighty-three cases was as follows: below five years, 27 cases; between five and ten years, 23; ten to fifteen, 25; between 15 and 20 years, 6; 20 to 25 years, 2. Of the twenty-seven cases in which the troubles came on within five years, six occurred under two years, four under three, six under four, and eleven between four and five years; the affections being hemiplegia, convulsive disorders and paraplegia. Optic neuritis was not observed under three years, but in the one-hundred cases occurred fifteen times; in twenty there was paralysis of orbital muscles; in five, disseminated choroiditis, and old iritis in two cases. The symptoms of the early nervous affections did not present any marked peculiarity from those of the later ones; they were of the order of vaso-motor irritation, such as disposition to fainting, contraction of retinal vessels, large pupil and acceleration of the heart. He had seen mental symptoms, in some cases almost maniacal, in early syphilis. He coincided with the hint thrown out by Mr. Hutchinson as to the relation of tertiary lesions to the secondaries through tissue change induced by the latter, and suggested that perhaps this occurred through the medium of the lymphatic system. He cited instances showing a tendency in syphilis for lymphatic canals and bursal sacs to be involved. The next speaker was Sir Wm. Jenner, who, being urged by

the President of the Society, with seeming reluctance made some short and significant remarks. He did not think that the manifestations of all acute diseases were symmetrical, nor that symmetry of distribution was necessarily an expression of blood disease. He thought that there were sequelæ of acute specific diseases which were in nature specific, and cited as instances the paralysis of diphtheria which were undoubtedly the result of blood disease. He evidently thinks, though his remarks were so terse and brief that we judge so only from their general tenor, that most of the so-called sequelæ of the exanthemata are really "mere accidental disturbances of nutrition." Thus far in the argument this is the only time that this aspect of the question of the nature of the sequelæ of the various affections has been broached, and it is to be regretted that it was not considered in all its bearings, as it is really vital to the question of the simile to determine really which are sequelæ of these exanthems and which merely, as very properly called, accidental disturbances of nutrition. The remarks of Sir William upon the pathology of infantile syphilis showed that he had studied closely into its nature, and we regret that he did not express himself at greater length and with more precision. He thinks that the sperm cell contains the infecting element of syphilis; that this body contains, as he terms it, "the potentiality of development," and that its chief and primary action is in the tissues, while the blood is secondarily involved.

Reviews and Notices of Books.

An Elementary Treatise on Diseases of the Skin. By Henry G. Piffard, M.D. Macmillan & Co., London and New York. 1876.

It may be accepted as a favorable indication of the rapidly increasing attention which is now being paid to skin diseases in this country, that we have here written by our American authors a systematic treatise upon them. Though Dr. Piffard's work is really not the first treatise on skin diseases written by an American, as Worchester published a quite extended volume in 1845, it may be said to be the first really scientific and noteworthy effort, as the older treatise was a simple compilation of indifferent merit. From Worchester's day until within ten years little was practically done in relation to these affections; but since that time many monographs of merit, upon skin diseases, have been published, and American authors came to be looked upon with respect on the continent. Among these physicians Dr. Piffard has occupied a prominent place, and it has been generally known that he has for years devoted his time and attention to the study of dermatology. Coming then from a man who has an acknowledged position as a dermatologist, the work claims our earnest attention; while as an exposition of American thought and experience it will be looked into very critically.

The first chapter is certainly, in every respect, an excellent one, and will very much influence the reader in the author's favor. The anatomy of the skin is there described in a simple and true manner, and the text is illustrated by plates, duplicates of those used by Sappey in his classical work on anatomy, the mere mention of which fact will attest their worth and appropriateness. The rudiments of the study of skin diseases are well given in the chapters on physiology, pathology, symptomotology and diagnosis. Indeed it is a pleasure to see this branch of the subject, so very necessary to one who wishes to understand dermatology generally, presented in such an admirably clear and simple manner. Much profit will certainly be derived from a thorough mastery of this portion of the work. Coming now to the vexed question of classification, we find that the author, true to the views which he has so long and strenuously advocated, adopts as a basis of his work a division of skin affections into groups based upon cause; in short, an etiological classification. It would be both unnecessary and inappropriate here to discuss this question, and we shall simply say that for those who believe that certain diatheses are the causes of cutaneous affections, the classification of the author will be acceptable; while for others it need not render the work less useful, as the question of causation is at best a moot point, and we have in the text other interesting and important matter in the way of general considerations, clinical history, therapeutics, *et cetera*. After a very good chapter on the syphilides, in which the author has evidently aimed at simplicity in their division, we come to the treatment of the varieties of lupus called by Dr. Piffard scrofulides. As he thinks they are the direct expression of a diathesis, he assumes the fact as settled forever, and does not address the merits of this question. In this chapter, in which Hardy's division is fully accepted, we find evidence of much original work in the microscopical study of the pathology of the various forms of the disease. The views of other observers are fully considered by themselves, and in the light of the author's experience. Perhaps some surprise will be excited in the mind of the reader when he finds that rodent ulcer is classed by Dr. Piffard as a variety of lupus, and that microscopical appearances have led him to adopt that view. This fact is strikingly suggestive of the suspicion that, although much can be done by the microscope to simplify the division of skin lesions, definite conclusions can only be arrived at after long years of extended and comparative study. Less exception, however, can be taken to the chapter on the treatment of the scrofulides (lupus), in which much practical information is given; indeed the directions for the management of these obstinate affections are noticeably superior to those of treatises in general. Following the scrofulides we come to the chapter on rheumides, under which term the author includes eczema, psoriasis and pityriasis, considering them an expression of a diathesis, which until now we have been familiar with, according to some authors, as the dartrous, herpetic or arthritic, but which, for reasons fully given by Dr. Piffard, he thinks should be called the rheumic diathesis. This morbid state is said to be that in which there is a condition of suboxidation going on in the tissues, which manifests itself by various affections, notably those of the skin.

In coming to these conclusions, the author has evidently been much influenced by the views of Gigot, Luard and Bence-Jones. We will not here further discuss the question, but will, in justice to Dr. Piffard, state that while he has advocated the existence of this hypothetical morbid state, he has also paid much attention to its investigation, and he considers the question involved in it in a thoroughly scientific manner

This question is one of too much importance to be slurred over or ignored; hence, due attention should be paid to the views of the author, as stated in his work. The fact of the adoption of the opinion by Dr. Piffard, that diatheses are, more or less remotely, the cause of skin affections, is interesting as showing how the views of French and English authors are accepted in this country, where, of course, they will be spread by Dr. Piffard, in his college lectures. While we speak with some hesitation upon the views of the author, as to causation, we must state our approval of the manner in which he has described the so-called diathetic diseases, and endorse heartily his clearly laid down directions for treatment. Indeed we may say here, as applying to all affections included in this book, that their clinical history is written in a simple, terse, and graphic manner; and further add, that the therapeutical portions are noticeable for their simplicity and appositeness. Space will not admit of the consideration of further affections in particular, therefore our further remarks will be general in character. Every affection liable to be met with is well described; all questions relating to it are fully considered; the views of others are given, criticised and accepted, when deemed proper by the author. There is evidence throughout the work of much study of the writings of others and of personal clinical observation. The descriptions given by the author show him to be a man who possesses the faculties of observation and induction in a marked degree. In no other similar work, except Neumann, can one find as much information upon the pathology of the skin, as developed by the microscope, as in the one under review; and much of its value is on this account. Dr. Piffard, however, has avoided an error which very greatly impaired the usefulness of Neumann's work; in making histological pathology only an accessory feature—and in devoting, as should properly be, the greater space to clinical history in general—so that his work is a guide to the clinic, and not to the microscope. In justice to Neumann it must be added, that his later editions have been improvements in this direction. Taking the whole work into question, we must express our decided conviction that it is an admirable guide to the study of skin diseases, and as such will prove, by reason of its terseness and simplicity of statement, a great help to those studying these affections. As a sample of American medical literature, we may certainly point to it with pride, as it will certainly compare favorably with the works which we now consider as classics; doing honor, not only to its author, but also to the country from which it emanated. The general "get up" of the book is all that one can desire; the type is large, clear and sharp, and easily read, and the paper and binding are excellent—indeed the work is like all emanating from the publishing houses of the Messrs. Macmillan; as nearly perfect as possible. Lastly, we must call attention to the numerous valuable illustrations, very many original, which, as works of art, are commendable; and as explicative of the text, excellent.

National Surgical Institute.—The "protest" sent to the New York Academy of Medicine by the "District of Columbia Medical Society," against the "bill to incorporate the 'National Surgical Institute,'" having been concurred in, was signed by the President and Secretary, and, under the seal of the Academy, forwarded to Washington, D. C. It was duly presented to the Senate by Senator Conkling, and referred to the appropriate committee.

Reports of Societies.

MEDICAL SOCIETY OF NEW JERSEY.

ONE HUNDRED AND TENTH ANNUAL MEETING.

The one hundred and tenth annual meeting of the Medical Society of New Jersey was held at Cape May on Tuesday and Wednesday, May 23d and 24th. Every district medical society in the State, excepting Somerset, was fully represented. Delegates from Maine, Massachusetts, Rhode Island, New York, and Pennsylvania medical societies were present. Among the invited guests we noticed Drs. Agnew, Pepper, Goodell, Atkinson, Dunglison, and Lewis, of Philadelphia.

The meeting was called to order at eight o'clock Tuesday evening; Dr. Wm. O'Gorman, of Newark, the president, in the chair. After the transaction of the regular routine business, the remainder of the evening was devoted to the reading of the annual address by the president, the subject of which was "External Influences on Medicine." The president in his address traced the influence of prevailing dogmas and systems of philosophy upon the progress and development of the science and art of medicine in a way that was at once new and attractive.

After adjournment the company, together with the ladies, in all about four hundred, sat down to an elegant banquet tendered by the physicians of Cumberland, Gloucester, and Cape May counties. Speeches were made by Drs. Agnew, Atkinson, Pepper, Cohen, E. M. Hunt, and Rev. Mr. Garretson and others.

PREVAILING DISEASES—PROGRESS IN THERAPEUTICS.

The Society reassembled at nine o'clock Wednesday morning, when the reading of the report of the standing committee was made the first order of business. The report was read by Dr. Wickes, the chairman, and exhibited, with a single exception, a diminished amount of disease throughout the State.

The ordinary contagious forms in children have appeared as before, measles being in the advance. Scarlet fever has appeared in less amount and with less serious manifestations than in former years. Fevers, remittent and intermittent, have not claimed the attention of physicians to any degree. Rubeola, or German measles, has prevailed extensively in Essex. Diphtheria has been the only serious epidemic, and it has been the scourge of the year. In Tuckertown, in a population of 800, there were 150 cases.

QUININE AND SALICYLIC ACID.

In therapeutics there seems to be a growing tendency to the use of very large doses of quinine. Chlorine, in the form of Tr. ferri chloridi and potassii chloras, has impressed many practitioners with its value as a topical application in malignant sore-throat and diphtheria. Salicylic acid has disappointed many, but in the hands of others has proved valuable when used locally.

ELASTIC LIGATURE FOR REMOVAL OF TUMOR.

Among surgical appliances is noted the employment of the elastic ligature for the removal of a malignant tumor from the subclavian region in a lady aged seventy, which measured in its longer diameter five inches, in its shorter three, had been four years de-

veloping, and four months in a state of ulceration, with a fetid discharge, and an occasional hemorrhage. The ligature gave but little inconvenience, and the general condition of the patient began to improve at once. In nine days separation was so nearly complete that the remaining tissue was cut with the scissors, not a drop of blood escaping. Cicatrization was complete in a month, and the patient's health was equal to that of most persons of her age.

TOPICAL APPLICATIONS IN MALIGNANT SORE THROAT.

The committee solicited replies from the reporters upon the following subjects: "The value of topical applications in malignant sore throat," and "In what degree calomel is relied upon as a therapeutic agent?" and deduced from their reports these conclusions as the sentiment of the Faculty.

As to the first:

1. Topical applications are not curative except it may be in the formative state of the disease.

2. They cannot with propriety be wholly ignored. They become valuable aids to successful treatment, as disinfecting, soothing, and cleansing agents.

3. The irritating and more heroic applications of a few years since are generally abandoned as hurtful.

4. The main reliance for cure must be placed upon remedies addressed to the morbid constitutional conditions.

As to the second:

1. That the very general opinion of our medical men is, that calomel is a valuable therapeutic agent.

2. That in many morbid conditions it is relied upon as the best.

3. That as a cathartic in certain cases, as an alterative in others, and as an antifibrinator, it is almost indispensable.

And the lesson which the discussion of the whole subject furnishes is, that a valuable drug should not be abandoned, and "its name cast out as evil," because it is unpopular.

The necrological list for the past year contains thirteen names.

A half hour was appropriated for remarks upon the report, which was improved by Drs. Hopper, Ridge, Rogers, Garnet, Cohen, and Atkinson.

MISCELLANEOUS PAPERS—MEDICAL HEROISM.

An essay was read by Dr. J. S. Cook on "Our Climate, and its effect upon Disease," which was well received and was ordered to be published in the Transactions. Other papers were presented, but for want of time were read by title only, and referred to committee on publication. One by Dr. E. P. Townsend, on "Medical Heroism," portrayed some of the trying scenes in which every physician must of necessity be placed, and the occasion where the highest type of bravery and courage are required,—not only the mere physical courage to perform operations, but the courage to work beyond the mere routine of authoritative medication and assume the control according to his own practical judgment.

MENTAL PATHOLOGY AND CRIMINAL LAW.

Another paper was by Dr. R. M. Bateman on "Mental Pathology and Criminal Law," in which he reviewed the subject under the following heads: Different hypotheses to explain the evidence of non-congenital insanity; increase of insanity; prevalence of moral insanity; difficulty in distinguishing real and simulated insanity; this difficulty, in diagnosis, used by criminal lawyers in behalf of their clients; the facility with which wealthy criminals escape punishment upon the plea of insanity; case of Charles K. Landis noticed at length; importance of a change in penal legislation; abolition of capital punishment advocated, and certain modifications suggested which would render punishment certain. The essay closed with a consideration of the duties of medical men in reference to the general question of "reform," especially in these times of corruption.

The degree of M.D. was conferred upon Louis Rein and Edward Mueller, of Hudson County. Dr. Weir Mitchell, of Philadelphia, was elected an honorary member. Dr. E. J. Marsh, of Paterson, was appointed Essayist for the next annual meeting.

DEATH OF DR. A. W. WOODHULL.

The following resolutions upon the death of Dr. A. W. Woodhull were adopted:

Whereas, This society has been informed of the death on the 14th instant, of one of its delegation members, Dr. Addison W. Woodhull, of Newark; therefore,

Resolved, That in his death we mourn the loss of one esteemed for his intelligent and faithful counsels; his discriminating judgment, his intellectual worth, his skill as a physician, and his patriotic services to the State and country;

Resolved, That in his death the country, as also the State, loses one of its most valued citizens, and that as fellow-members and co-workers in the profession, we deeply feel this sad bereavement, and we extend our sympathies to his stricken family and friends;

Resolved, That this expression of the feelings of this society be entered on the minutes, and a copy be sent to his family.

ELECTION OF OFFICERS.

The following were elected as the officers of the Society for the ensuing year: President, John V. Schenck; Vice Presidents, H. R. Baldwin, John S. Cook, and A. W. Rodgers; Corresponding Secretary, Wm. Elmer, Jr.; Recording Secretary, Wm. Pierson, Jr.; Treasurer, W. W. L. Phillips; Standing Committee, S. Wickes, S. Lilly, and J. L. Bodine.

Delegates to American Medical Association for 1877.—H. A. Hopper, S. C. Thornton, H. G. Taylor, T. J. Smith, W. Love, P. S. Heritage, J. W. Hunt, Samuel Lilly, E. P. Cooper, S. B. Brown, J. R. Leal, H. R. Baldwin, Wm. Armitage, John Vought, Joseph Hedges, T. H. Tomlinson, and P. F. Brakely.

New Hampshire: C. O. Gordon. *Connecticut:* E. J. Marsh. *New York:* E. B. Silvers, H. Mitchell, Jos. Parish, E. Maston. *Pennsylvania:* C. H. Voorhees, H. C. Clark, Wm. Elmer, Sr., and W. Blundell. *Rhode Island:* C. F. Deshler, T. J. Thomason, and S. Lilly. *Massachusetts:* J. J. Pendergast, J. L. Bodine, J. B. James, and J. G. Ryerson. *Maine:* G. H. Balleray, B. F. Carpenter, C. O. Gordon.

International Medical Congress: J. M. Ridge, John Woolverton, Ezra M. Hunt, John C. Johnson, Charles Hasbrouck, Abram Coles, and A. A. Latkins.

The next meeting of the Society will be held at Trenton.

MEDICAL SOCIETY OF COUNTY OF NEW YORK.—At a Stated Meeting of the New York County Medical Society, held May 22d, 1876, the following gentlemen were elected members: Drs. Charles Stein, Philip F. Goldberg, Henry C. Eno, Emil W. Hieber, Frederick Lemcleder, and Robert Abbé.

On motion, the Secretary was authorized to furnish credentials to members desiring to serve as delegates to the American Medical Association at its session in Philadelphia, commencing June 6th, 1876.

CENTENNIAL MEDICAL AFFAIRS.

(From our Special Correspondent.)

GOVERNMENTAL CONTRIBUTIONS—HOSPITALS OF THE MEDICAL DEPARTMENT OE THE U. S. ARMY—THEIR ARRANGEMENT AND METHODS OF CONSTRUCTION.

PHILADELPHIA, May 29, 1876.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—The crowds that daily throng the avenues of the Exposition buildings, and wander—often aimlessly—through the attractive grounds surrounding them, generally take but little heed of numerous interesting features which professional men alone can thoroughly enjoy and appreciate. Occasionaly the promiscuous sight-seer strays into the building of the U. S. Army Medical Department, but with a puzzled air, as if he did not quite comprehend all that he saw in it, or as if he were merely paying a brief visit to an expectant hospital, awaiting the arrival of sick and wounded occupants of its beds; whereas it is only a model of a post hospital in all its details. Through various portions of the Exposition the medical feature is one of great moment, and well worthy of study. There is a prospect, during the present and the ensuing week, that an army of medical explorers will make diligent search for all these treasures of science and art. The State Medical Society of Pennsylvania, to meet on Wednesday afternoon next, in this city, will undoubtedly be the largest representation of medical men of this State that has ever assembled. The temptation to visit Philadelphia at this time is so great, that each county delegation will probably be complete without a single vacancy. Many of these gentlemen will remain over until the following week, to take part in the deliberations of the American Medical Association. How many delegates will be present on the latter occasion it is difficult to predict; but, from the preparations made by the Committee of Arrangements for their entertainment, it is fair to presume that from fifteen hundred to two thousand members—new and old—are expected. In the hurried view of the exposition that most of our medical brethren will take, the isolation of the purely professional portions from the other attractions offered will be simply an impossibility. We would not suggest to them any programme that would embarrass them in the limited time they must necessarily allot to the whole grand display. The main building being close at hand, after the visitor passes the registering turnstiles, at one of the numerous entrances to the grounds, he naturally wends his way at once to its capacious aisles, and, in the general admiration of everything æsthetically beautiful, he forgets for a while his own special medical tastes and professional inclinations, and possibly passes slightingly objects of peculiar interest to him as a physician. Probably the most satisfactory plan to pursue, in order to study systematically the medical aspects of the Centennial, would be that which we propose to follow in the present series of papers upon the subject. Giving the first place to Governmental contributions to the Exposition, the individual exhibits, although of equal importance, will claim subsequent consideration.

The U. S. Government Building occupies a prominent position in the Centennial Exposition, not only from its imposing character externally, but from the varied nature of its contents, which embrace the chief features of utility, development, and working machinery of each department, and of the Smithsonian Institute. It occupies about two acres, and forms an excellent exhibit of the resources of the country, so far as they are controlled and conducted by the general Government. There is much here that will interest the medical man from its purely scientific character. The *Model Army Hospital* is, however, a distinct building, only a few yards distant, and what may be termed an annex to it. It is designed to represent the system of hospital construction actually employed by the medical service of the army, both in peace and war. Several pamphlets—from which we take the liberty to quote—have been issued by Asst. Surgeon J. J. Woodward, U. S. A., explanatory of its construction and of the appliances of various kinds on exhibition here. At the close of the recent war, great diversity existed in the style and arrangement of post hospitals, and it was soon found expedient to attempt to secure greater uniformity by establishing general regulations for their construction. These hospitals were, by order of the War Department, planned to contain twelve, twenty-four, or thirty-six beds, and, after various modifications, rules for their construction were approved by the Secretary of War, and issued as Circular No. 2, S. G. O., July 27, 1871. The regulation post hospital for twenty-four beds, which have been built in the Exposition grounds, is described as a frame building, with a shingle roof, surrounded by a veranda. It consists of a central administration building, 35 feet front by 39 deep, and two stories high, with a two-storied back-building 40 by 14 feet, and two wings 45 feet by 24, one for each ward of twelve beds. The floor of the whole building is raised three feet above the ground, and is well supported on timber posts. In the plan of the ground floor are the wards, each 24 ft. by 45; dispensary, 14 ft. by 15; office, 14 ft. by 15; mess-room, 14 ft. by 20; kitchen, 14 ft. by 14; nurses' room, 14 ft. by 15; earth closets, each 9 ft. by 9; bath-room and lavatory; closets; pantry, 8 ft. by 10. In the plan of the second story is the steward's room, 14 ft. by 15; spare room, 14 ft. by 15; attendants' room, 14 ft. by 19; store-room, 14 ft. by 15; room for violent patients, 14 ft. by 20. All the walls and ceilings are lathed and plastered with two coats, the finishing coat being plaster of Paris, and the entire woodwork, usually painted, is covered with two coats of paint.

The wards are 15 ft. high in the clear from floor to ceiling. Ridge ventilation is provided for the summer months by means of two boxed openings in each ward, carried from the middle line of the ceiling to the ridge. These openings are 10 feet apart, and are each 10 feet long by 2½ feet wide. In the winter months the opening at the ridge is to be closed, and ventilation effected in the following manner: A large stove is placed in the middle of the ward. Fresh air is introduced by an air-box 18 inches square, which passes underneath the floor of the ward from side to side, open at each extremity to the external air, and opens in the centre of the ward beneath the stove by means of a register; when a ventilating stove is used, the place of the register is occupied by a pipe, which connects the air-chamber of the stove with the air-box beneath the floor. The pipe of the stove passes up through a close-fitting collar in the ceiling. One foot above the ceiling it enters a shaft or jacket about 24 inches in diameter, which pierces the roof, and extends four feet above; it is covered with a sheet-iron cap, pierced in its turn by the stove-pipe, which is capped in the same manner. At each end of the ward, and two

feet from the centre, there is an opening in the ceiling one foot square, from which an air-box passes to a box enclosing the lower mouth of the shaft surrounding the stove-pipe. The heat of the stove-pipe causes a continuous upward current in this shaft, which is supplied by the vitiated air from the ward through the air boxes. In each of the earth closets there is a ventilating shaft six inches square, and the gas-burner of the room is situated directly beneath it. These earth closets in the regulation hospitals are intended for very sick patients only, accommodations for other patients and the attendants being provided in a suitable detached building. A small detached building is also intended to be provided for the purposes of a dead-house; and cases of small-pox and other contagious diseases are to be treated in hospital tents.

In fitting up this building for the Exhibition of 1876, the rooms are occupied as follows: On the first floor a ward, serving for the exhibition of hospital furniture, bedding, and clothing; a room for the exhibition of the models of hospitals, hospital steam vessels, hospital railway cars, ambulances, etc., and for specimens from the Army Medical Museum; while the other rooms are used for the exhibition of medicines, medical stores, and chemicals; surgical instruments, books, blanks, and the publications of the Surgeon-General's Office, mess furniture and utensils, kitchen utensils, and the private office of the surgeon in charge, and the rooms in the second story serve for the exhibition of prothetic apparatus, litters and stretchers, medical panniers, knapsacks, etc.

The five small models of hospitals on exhibition represent a barrack ward, as adopted by the War Department in the summer of 1864, and four of the great general hospitals, so-called, which attained celebrity during the war.

The officers on duty at the Model Post Hospital, at the Exhibition grounds, are Asst. Surgeon J. J. Woodward, U. S. A., and Asst. Surgeon H. C. Yarrow, U. S. A., with Hospital Steward F. D. Price and clerk; and several other hospital stewards, selected from the different departments, are on duty here.

We learn also that the models of hospital cars and vessels on exhibition in this building are intended to represent especially those methods of adapting the ordinary rolling-stock of American railroads, and the ordinary steamboats of the interior rivers of the United States, and the merchant steam-vessels of the Atlantic coast, to the transportation of sick and wounded soldiers, which were found to be most satisfactory during the late war.

R. J. D.

DUMB-BELL PESSARIES, Etc.

To the Editor of The Medical Record.

Sir:—My attention has been called to the discrepancies between the cut intended to illustrate the position of the "Dumb-bell Pessary" and the text of my article in the Record for May 6th in reference to the same. Upon reading the article by Dr. Page, in the Record of the date of the 20th, I find that he has been misled by this unfortunate cut, and I fear other readers, through its agency, may have misconceived the application of the instrument.

The figure of the section of the pelvis was selected by the artist from Gray's Anatomy, and the instrument adapted to it. It shows simply the position of the instrument with its bulbous extremities before and behind the cervix, and that, as will be seen, in a case of over-distended bladder. This cut represents the pessary in a disposition in which, as Dr. Page says, the support must depend upon a tenacity of the vaginal walls which is not found generally in cases of displacement. Now my recommendation of the instrument was based expressly upon its having given support in a case of relaxation of the vagina, in which all other forms of pessary had proved inadequate.

In Dr. Page's article in the last number of the Record, he gives three cases illustrative of his employment of his pessary; Case 1 is of prolapsus; Case 2, of anteversion; Case 3, of retroversion. In cases 1st and 2d, of prolapsus and anteversion respectively, the instrument was introduced between the anterior surface of the cervix and the posterior surface of the pubes. In Case 3d, of retroversion, one bulb was passed up into the cul-de-sac behind the cervix and the other rested against the pubes. From this it is plain that, to a degree, I misunderstood Dr. Page's mode of application of the instrument, supposing that it was in all cases used as in Case 3. It is in this mode of employment of it alone that I have had any experience, and I took it to be the mode of its employment in all forms of uterine displacement.

The case which furnished the text of my article was one of anteversion. This class of cases, it appears, have thus far been treated by Dr. P. by placing the instrument between the pubes and the cervix. It seems to me impossible that in my case this use of the pessary could have been successful; when, however, in virtue of the curvature of the instrument, the posterior bulb is carried up into the posterior cul-de-sac, the anterior rising up behind the pubes, the success was complete. The instrument employed in this manner acts on the principle of Hodge's horse-shoe pessary with a single curve. In Hodge's the distension of the vagina is mainly from side to side. It will be readily understood how much higher up in front or behind the cervix an extremity of the dumb-bell pessary can be carried than one of the horse-shoe; almost as high as the fingers can be carried, anteriorly or posteriorly as the case may be. It thus becomes a means of holding the uterus, after its reduction, more or less in its normal position. In this respect it imitates Hurd's or Grailly Hewit's anteversion pessary, or particularly that of Dr. Thomas's well-known anteversion pessary. Over the latter instrument the dumb-bell pessary has the great advantage that the instrument of Dr. T. cannot be introduced by the patient herself, while the dumb-bell can be introduced, always premising the knee and and breast position, with great ease.

In many cases of aggravated anteversion, with extreme relaxation, it has been found impossible to restore and maintain the uterus in its normal position as regards the axis of the pelvis, and our best gynecologists have been obliged to content themselves with simply supporting the uterus in the pelvis by any expedient that would accomplish this alone, disregarding the error of position, thus allowing a return of free circulation through the uterus. It is the obstruction to the circulation, sometimes to an extent to cause œdema of the organ, that often perpetuates the malposition. The dumb-bell raises the uterus bodily, and maintains in a position more or less corresponding to the axis of the pelvis.

In any case, if the anterior wall is unyielding, the anterior bulb will rest upon it, or rest against the posterior border of the pubes, while if relaxed the bulb will pass up correspondingly high in front of the uterus—the greater the relaxation the larger the instrument and the larger the bulb required. In this respect the instrument made with its bulbs of thin

rubber, has advantages. By the hypodermic needle and Davidson's Syringe either bulb can be expanded to a size to adapt it especially to the case in hand.

I claim nothing as my own in connection with this instrument; the credit of its invention and introduction is due to Dr. Page alone.

In regard to the "knee and breast position," I cannot refrain from again expressing my sense of its great value as a means of relief and of permitting the easy introduction of pessaries.

The practitioner who has not yet tried it should be apprised, that when his patient assumes this position, if he simply introduce his finger into the vagina, the atmospheric pressure will crowd the soft parts about his finger, and he will detect a certain amount of subsidence of the organs of the pelvis. Let him now lift up the perinæum or substitute the glass dilator of Dr. Campbell for his finger, and the atmosphere will rush in with a distinctly audible noise and he will, on again introducing the finger, be amazed at the change that has taken place.

JAS. D. TRASK, M.D.

ASTORIA, N. Y.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from May 20th to May 27th, 1876.

McCORMICK, CHARLES, Surgeon. To report in person to the Surgeon-General of the Army. S. O. 99, A. G. O., May 19, 1876.

CALDWELL, D. G., Asst. Surgeon. Granted leave of absence for one month, with permission to apply for an extension of one month. S. O. 90, Dept. of Texas, May 19, 1876.

FITZGERALD, J. A., Asst. Surgeon. Assigned to duty as Post Surgeon at Fort Lapwai, Idaho T. S. O. 54, Dept. of the Columbia, May 8, 1876.

BYRNE, C. B., Asst. Surgeon. When relieved by Asst. Surgeon Meacham, to report immediately in person at these Headquarters for assignment. S. O. 90, C. S., Dept. of Texas.

COMEGYS, E. T., Asst. Surgeon. Assigned to duty as Post Surgeon at Fort Duncan, Texas. S. O. 86, Dept. of Texas, May 13, 1876.

Medical Items and News.

CONTAGIOUS DISEASES.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending May 27, 1876.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.

May 27.....	0	3	71	1	35	71	11

AMERICAN NEUROLOGICAL ASSOCIATION.—The second annual meeting of this Association will be held at Association Hall, on Wednesday, June 7th, at two P.M.

THE SEASIDE SANITARIUM FOR DESTITUTE SICK CHILDREN, at the Sea-View House on the Long Branch Railroad, is about to be opened. An appeal to the public is made for money, clothing, bedding, etc.

FORENSIC INSTITUTE OF BERLIN.—The Berlin University enjoys the advantage of a forensic institute, which is connected with the morgue—*i.e.*, an establishment for the exhibition of all corpses found by the police or sent for medical inspection, and, as the case may be, for a forensic post-mortem. If the latter is ordered by the judicial authorities, students are not admitted, except as spectators or attendants on any demonstrations which the professor might give after the necroscopic proceedings. Those corpses, however, which are not disposed of in this manner are at present utilized to give the students facilities for performing a quasi-legal post-mortem themselves, in accordance with the new regulations drawn up for all forensic autopsies in Prussia last year. It is stated that during the five months since November last, when this practice has been followed, not less than fifty post-mortems have been made by the forensic students, mostly in cases of violent and sudden deaths. An institution like our coroner's inquest does not exist in Germany, though competent voices have been demanding something like it for a long time. So far, the judge's mind is the sole arbiter for an inquiry and the order of a legal post-mortem. The establishment of some central institution for this special purpose, in a great metropolis, connected with a medical school seems, however, to furnish unusual advantages for efficient performance of the work as well as for the progress of forensic medicine.—*Lancet.*

ASSOCIATION OF AMERICAN MEDICAL EDITORS.—The members of this Association will meet in the parlors of the Continental Hotel, in Philadelphia, Monday Evening, June 5th, 1876, at eight o'clock promptly. F. N. Davis, Secretary.

NEW YORK WOMAN'S HOSPITAL.—At a meeting of the Board of Governors of this hospital, Drs. Paul F. Mundé and A. A. Smith were appointed Assistant Surgeons on the service of Dr. Fordyce Barker.

FIRE-DAMP AND THE BAROMETER. — It is maintained by French savans that an explosion of fire-damp can be predicted thirty-six hours in advance by a fall in the barometer, and a warning signal service is suggested in France.

THE KENTUCKY INFIRMARY FOR WOMEN AND CHILDREN, at Louisville, was formally dedicated on the 22d ultimo. It consists of a three-story brick building, well adapted for the charity intended. The Medical Staff is as follows: Dr. David Cummins, Orthopædic and General Surgery; Dr. B. F. Grant, Diseases of Women and Children; Dr. Geo. W. Griffiths, Diseases of Women and Children; Dr. Richard C. Brandeis, Diseases of the Eye, Ear, and Throat.

SPECIAL HOSPITALS.—The *Lancet* deprecates the multiplication of small hospitals for the treatment of special diseases, and very properly favors the establishment of special departments in the large general hospitals.

CHARRIÈRE, the celebrated surgical instrument maker of Paris, died May 6th.

THE DEATH RATE OF PHILADELPHIA is officially reported as only 19.3 per thousand. The mean annual temperature for the last ten years has been 53.73°, and the average annual rain-fall about 45 inches.

Original Communications.

A CASE OF PERITYPHLITIS

WITH PERFORATION OF THE APPENDIX VERMIFORMIS AND RUPTURE OF THE WALL OF THE ABSCESS, CAUSING GENERAL PERITONITIS AND DEATH, SEVENTY-FOUR DAYS AFTER THE ABSCESS HAD BEEN FREELY OPENED, WITH REMARKS ON THE OPERATION.

By ERSKINE MASON, M.D.,

PROFESSOR OF CLINICAL SURGERY, UNIVERSITY MEDICAL COLLEGE, NEW YORK.

On February 26, 1876, I saw, in consultation with Dr. Daniel C. Logue, a gentleman 32 years of age, of very delicate constitution, suffering from an attack of perityphlitis with abscess. I had previously (Jan. 18th of the same year) seen him in consultation with Dr. L. while suffering from an inflamed irreducible hernia of the left side, which he had had since early childhood. The history of his present difficulty, as related to me by Dr. L., was as follows: On the 10th of February he ate heartily of mince pie at a late dinner. Soon after this he was taken sick at the stomach and vomited, and on the following day, while at his business, he complained of feeling "very chilly most all the time." The succeeding day while returning from his office in the afternoon, he was seized with violent pain in the ileo-cæcal region. He described this pain as being "most intense," and with difficulty he reached home. Shortly after reaching his house he was seen by Dr. L., who at once placed him under the influence of morphine, and the pain still being localized, the succeeding evening several leeches were applied, which afforded relief. Recognizing that in all probability there might be some difficulty about the caput coli or perforation of the appendix, he was kept quiet under the influence of morphine. His pain never radiated over the abdomen, but was confined to the ileo-cæcal region; though for several days the abdomen was very tympanitic. Four days previous to my seeing him, the bowels were moved by warm-water enemata, and he had several large evacuations without pain. At the time I first saw him his bowels were being moved without artificial means and without his knowledge.

My visit was made at 11¼ A.M. I found him, on the 16th day from the time he was first taken sick, with his knees drawn up, tongue dry and red, pulse 100 and temperature 102°, skin moist, and for several days previous had had some sweating, and this morning had vomited. He had not experienced any chilly sensation since he took to his bed, though during my visit he was seized with a chilly sensation.

Examination of the abdomen revealed the following: Upon the right side, extending from the iliac fossa, was observed a distinct tumor, dull on percussion, and which could be clearly defined—measuring in its vertical diameter to Poupart's ligament, 5 inches—transverse diameter, 5 inches. No especial pain over greater portion of the tumor; more localized at lower portion of tumor at Poupart's ligament. The rest of the abdomen was free from pain upon pressure, and its walls very supple. The diagnosis was only too evident of ileo-cæcal abscess, with possible perforation of the appendix. I advised immediate operative interference, but for several reasons it was deferred until the following day.

Feb. 27, at 11¼ A.M., I saw him again. His general condition was more comfortable, and he expressed himself as feeling better. Had vomited from the time of my previous visit till 7 in the evening. This morning had taken considerable mutton broth and enjoyed it; pulse 100, temp. 101°. No pain except over lower portion of the tumor, where abdomen was examined. The tumor had however increased, spreading one inch more towards the left side, and had also extended upwards, and the umbilicus was now somewhat projected. There had been no movement of the bowels since yesterday. It was now decided to operate at once, the patient and his friends fully recognizing the propriety of the same.

So strenuously was the patient opposed to the taking of an anæsthetic, that I yielded to his desire, and operated without it. Previous to opening the abscess I attempted a digital exploration through the rectum; owing, however, to the presence of an inflamed pile, this attempt caused such pain I was obliged to desist.

Benumbing the skin by application of ice, I introduced a No. 3 trocar, attached to the aspirator, into the tumor, at a point half an inch to the left and two inches above the anterior superior spinous process of the ilium. Pus, but chiefly a fluid like bloody serum, issued rapidly into the aspirator, and a pint was in this way evacuated. I then passed a curved bistoury along the side of the trocar as a guide, and enlarged the opening for an inch and a half. This incision gave rapid exit to another pint or more of the same purulent fluid, together with large shreds of a brownish material.

The finger introduced through this opening recognized distinctly the caput coli bound down in the fossa; the finger could readily be swept around in the cavity of this large abscess. No portion of intestines was detected save the caput coli. A tent was now introduced through the wound, and lower portion of abdomen covered by a carbolized poultice. There was but little odor to the fluid evacuated, and we could not be certain that it was, strictly speaking, feculent in character. He bore the operation remarkably well, and said he felt greatly relieved. Half an hour after the operation, when I left him, the abscess was still freely discharging.

Feb. 28.—Patient very comfortable, had passed a good night. Appetite better than for some days past; pulse 96, temp. 100½°. The poultices had been changed every two hours. Abscess had discharged copiously and still running freely. A small dose of morphine had been taken every four hours, and was ordered to be continued if circumstances required it.

March 1.—Patient has done well since my last visit. Pulse 96, temp. 100°, is free from all pain, tongue moist, appetite good. Abscess still freely discharging, though the fluid, still chiefly of the same character as at first, is more shreddy. Ordered quinine, two grs., three times a day. Otherwise, same treatment continued.

March 10.—General improvement has been steady since last note. Has taken no morphine for past four days. Last night during a movement of the bowels, which was natural, his hernia increased in size and became painful, and this has rendered him a little nervous. Discharge constant and abundant, last forty-eight hours become much more purulent and thicker, is of a strong feculent odor, several dark masses have been discharged, evidently fecal matter. A small mass of dark sloughy tissue was found on the poultice this A.M. This was handed to a gentleman for microscopical examination, but unfortunately it was mislaid by him, therefore as to its character we are unable to speak definitely. To the eye and feel, however,

it seemed to be a portion of intestine. I suggested the abscess be daily washed out with warm carbolized water.

March 29.—Dr. L. informs me to-day that he has daily washed out the abscess since my last visit. Patient did well till the 25th, when he had a slight rigor and his appetite failed. Has been sitting up in his chair for two or three days. On the afternoon of the 25th, was seized with pain on left side in the region of his hernia; but after a few hours this passed off. 27th, had a return of this same pain, and the pulse rose to 102, temp. to 102°. 28th, had a hard chill in the morning, and sweat all the day and evening, great loss of appetite, with great thirst, very drowsy, no pain over abdomen. Discharge for past few days has been very little and has had no feculent odor since I last saw him. Cavity of abscess will not now hold more than 2 oz. of water; when first washed out it would hold a pint before there would be any return of the fluid. I saw him this morning, found he had passed a very comfortable night, had more appetite for his breakfast than for some days. During the night abscess again began to discharge pretty freely thick yellow pus, free from feculent odor; pulse had fallen to 96, temp. 101¾°. I introduced a drainage tube, which passed in towards the left side, about 4½ inches. The induration of the lower portion of the abdomen which had always been present, had softened considerably on the right side, while in the median line and towards the left it was still well marked.

May 9.—I was requested to-day by Dr. D. L. Smith, who during the temporary absence of Dr. Logue from the city was taking charge of the case, to see the patient with him. Ever since my last visit he had been slowly gaining in strength, the discharge from the abscess was very slight and thin in character. Was sitting up for a short time each day, and two weeks ago changed his residence, which necessitated his riding a distance of about three miles, which he bore without any unpleasant circumstances, and so comfortable was his condition that he contemplated going into the country, a distance of several hundred miles, in a few days. The following is the statement made me by Dr. Smith, when he called on me to-day. May 7th, he complained of some pain in his right side, and on the 8th the pain had increased, and there was some tympanites; it also gave him considerable pain while washing out the abscess, so the doctor desisted from using the water as freely as usual.

At 1 P.M. on the 8th he had a hard chill, and another between 6 and 7 in the evening. At 9½ P.M. his pulse was 142, respiration 36, temp. 105¼°. Had been vomiting all the afternoon; abdomen tympanitic and painful upon examination. Was placed at once under morphine and quinine. Passed a restless night, and on the morning of the 9th, between 7 and 8 o'clock, he had another chill. Discharge from the abscess profuse, serous in character and strongly feculent in odor. Wind was also escaping from the opening, which was now very small. Stomach very irritable, nausea and vomiting being pretty constant. At 12 M. pulse 120; resp. 28; temp. 102½°; complains of great weakness.

I saw him about 2 P.M., and found his condition just as above stated. He complained of no pain, upon examination of the abdomen, which was very tympanitic, and the opening of the abscess was very livid and emitted a very offensive odor. Our patient was very evidently fast sinking, and as I supposed from the giving way of the walls of the abscess, a new perforation, or both, resulting in a general peritonitis. He sank and died May 11th, at 4 P.M., retaining consciousness till a half hour before his death.

Death occurred ninety-one days from the time he was first taken sick, and seventy-four from the opening of the abscess.

The following morning, under the greatest difficulties, we were enabled to make a partial autopsy. Upon opening the cavity of the peritoneum air freely escaped. The omentum was bound down over the small intestines by recent adhesions, and greatly discolored, almost as black as charcoal. Peritonitis was general, and the cavity contained serum with flakes of lymph and fæcal matter. The wall of the abscess was half an inch in thickness, surrounding and binding down the caput coli and the appendix; it also extended across the median line two inches below the umbilicus. Its cavity containing fæcal matter, would now not hold more than two and one-third ounces of fluid. It had broken into the cavity of the peritoneum on its posterior border, a little to the left. The caput coli, with the appendix, were so bound down, that it would have required more time to have removed it intact, than was given to us to make the examination; I am therefore unable to state exactly at what point the perforation in the intestine took place; but it was near the junction of the appendix and caput coli.

Remarks.—There are several features in this case which are to me of striking interest, and some of which I do not recall having seen mentioned in cases that have heretofore been published. If my memory serves me right, there are few, if any, cases in which an operation has been performed, where it was deferred to so late a day, viz., the seventeenth from the date of the attack. When the presence of a tumor could first have been detected in this case, I am unable to state; the doctor's attention was called to it, it is true, a day or two before I saw the case, and I believe he regarded it as sudden in its manifestation. Be that as it may, it had increased very rapidly.

The size of the tumor certainly was unusually large, and the amount of fluid at once discharged, exceedingly so. I have no recollection of reading of a case where such a quantity of fluid was at once discharged, and where the discharge, profuse at times, kept up almost constantly, with but slight interruptions for so long a period, viz., seventy-four days. The discharge from these abscesses, I believe, has always been decidedly purulent from the time of opening, and, in many cases, decidedly feculent in character. Such was not the case, however, in this instance; the discharge, at first, and during various intervals, being thin, watery and resembling bloody serum, though always, it is true, containing pus. It never became what could be called properly feculent in odor until several days had elapsed, when feculent material also issued from the opening.

With all this accumulation in the abscess, there was, and had been, up to the time of my first visit, not that amount of constitutional disturbance which one might expect to see in such a case. The second day after he was first seized, it is true, while at his place of business, he complained of feeling chilly all day. But from that time till my visit he never complained of any such sensation.

As to the mode of death:—When it occurs from perforation of the appendix, I think it will be found to take place on or before the sixth day in the majority of cases, and where abscess occurs, as a result of perforation or perityphlitis, and rupture into the peritoneal sac, causing death, they do so also at a comparatively early date. No case have I seen recorded where after so long an interval has elapsed from the time the

abscess was opened, and where its cavity was diminishing in size, and it seemed probable it would soon close, has it been known to have given way, causing speedy death.

If in any case we could suppose that such an accident would be prevented, by an external opening, we certainly would have thought that this case would be spared such a catastrophe. Had the opening been too small to allow the ready exit of matter, this perhaps might have been a cause of the result, but such was not the case. It admitted readily the escape of pus, and was freely injected every day.

On the part of some it might be urged that had a freer opening been made in an abscess the size of this, and then had it been dressed from the bottom with oakum or lint, as was done in some of the earlier cases operated on, the cavity would have been closed sooner and this accident of rupture of the sac would not have occurred.

I am not quite willing to view the case in this light; for the original incision, an inch and a half, certainly appeared large enough at the time of the operation to give ready vent to its contents, and the steady yet gradual contraction of its size certainly did not, it strikes me, call for any further interference on the part of the surgeons. Again, from cases that have been reported since Dr. Parker first drew the attention of the profession to this operation, it would seem that the large incision first made was not necessarily indicated, an opening that admits the free escape of pus being all-sufficient. As to the method of performing this operation, I would give preference in the majority of cases to the use of the aspirator first. This indicates at once the presence of pus, and if pus is not detected the least injury has been done; then the trocar affords a safe guide for the incision by the bistoury. The cause of the fatal termination of this case was of course perforation of the walls of the abscess, and escape of its contents into the peritoneal cavity, and general peritonitis ensuing. With such thick walls (they being a half inch or more in thickness), and at so late a stage of the operation, one would scarcely imagine they would be liable to give way. My theory in reference to this accident in my case is this: the opening of the intestine into the abscess had not yet been closed, and some foreign body passing from the intestine had lodged in some recess in the walls of the abscess, the daily injections which the abscess received were not successful in removing the same; and it, acting as a foreign body, excited irritation and ulcerative action, which resulted in a perforation into the peritoneal cavity, in precisely the same manner as we, unfortunately, frequently find a foreign material or hardened fæcal matter act in the appendix. If this idea is correct, it only proves, though it was unsuccessful in this instance, the necessity in the after-treatment of these cases, to resort after the first few days to a careful irrigation of the abscess. Its use certainly is beneficial in many ways, as we can not only keep the patient more cleanly, but we can diminish any disagreeable odor the discharge may possess, and by such cleanliness, we in this, as in other surgical operations, lessen the risks of septic infection. Though the attention of the profession, within the past few years, has been forcibly called to the subject of perityphlitic abscess, at least in this city, from the very striking and favorable results which have followed upon operative interference, still there is much for us yet to learn in connection with these cases; and until this operation has been thoroughly popularized, and the great benefit that is likely to accrue from operative interference more fully comprehended, I think it becomes the duty of those who have to deal with these cases, to give publicity to their cases, whether they are fatal or successful. These abscesses, it is true, have opened of themselves, both externally and into the bladder and intestine, and the patient recovered. But it would not be safe practice to wait, hoping for such a result to happen in every case. I have, within a comparatively short period, met with two cases where the abscess has discharged itself into the bowels and the patients have recovered. One case was a boy about 11 years of age, who had been suffering from symptoms of localized peritonitis in the right iliac fossa for several days, and where no tumor was detected. One night he had a rather free discharge of pus and blood from the bowel, and his symptoms rapidly abated. The other case was that of a gentleman about 37 years of age, in whom at my first visit one evening, a tumor was readily detected, but feeling easier at the time of my visit, an operation was postponed for suitable reasons; that night he had a copious discharge of pus from the bowel, and recovered. I have also met with two cases, where, following the usual symptoms which are supposed to indicate perforation of the appendix, or a localized peritonitis in the right iliac fossa from some other cause, small hard tumors were readily detected, yet under poultices and counter-irritation the symptoms gradually subsided and the patients recovered. One was in the person of a medical friend, whose case I watched with great solicitude for several weeks; the other, in a lady of middle age. I know similar cases have been met with, and the question to be solved, and one of great difficulty in these cases, is this: Do these tumors, just described, result from a collection of pus, or are they the result of some other inflammatory product? It is not within the scope of these remarks to discuss this point at present, but from their diminishing in size and eventually disappearing under treatment, I believe them due to plastic effusion alone; the result of a perityphlitis, probably without perforation. When abscess has already formed, it has at times been with great difficulty detected, owing to the great sensitiveness of the abdominal walls preventing a thorough examination, or to their distention from tympanites. One other cause which might mislead, is the cæcum becoming gradually distended with fæces. I have never seen this spoken of as a source of error in papers upon this subject, though I have met with it in practice in a case dying of perforation and general peritonitis on the sixth day. Here I thought there was an abscess forming, both from the sense of touch conveyed through the abdominal walls, as well as there being circumscribed dulness on percussion. When we are enabled to make it, rectal exploration will often throw great light upon the case, if not entirely clear up the diagnosis.

Though these remarks have been extended far beyond my original limit, I cannot close them without an allusion to the literature of the operation for the relief of these cases, and which has saved so many from an untimely end.

In my own mind there is not a question as to whom we are indebted for bringing this operation forcibly to our notice and popularizing the same, and it was he also, as far as we have been able to ascertain after some research upon the subject, who first did the operation.

The first published account of this operation that we have been able to find, is a case related by Mr. Hancock to the Medical Society of London, in 1848, he at that time being its President. The operation was done April 17th, 1848, and an account of the same is published in the London *Medical Gazette* for

1848, page 547. At the meeting in which this case was recited, considerable discussion, it seems, was called forth from the members on this subject. The operation, it would seem, did not meet the favorable adoption in England that it was entitled to, though the operation was successful, as we find no illusion to it by other English surgeons. Nor did the announcement of this case meet with a more favorable reception by surgeons in this country, though the case was republished in the January number of the American *Journal of the Medical Sciences* for 1849, page 193. Dr. George Lewis, also of this city, in the New York *Medical Journal* for 1856, in his elaborate paper on "Abscess and other Diseases consequent upon Lodgment of foreign Bodies in the Appendix Vermiformis," when alluding to Mr. Hancock's case in detail, advocates this operation. In spite of all this publicity given to the operation, and in the face of the fact, that the large majority of these cases if left to themselves, perished, it apparently was lost sight of.

It was not till 1867, when Dr. Willard Parker published his paper on this operation, in the MEDICAL RECORD for March 1, 1867, giving the history of four successful cases, that the operation was at once received by the profession, and became established among the very successful operations in surgery. His first operation was upon the person of a medical man in 1843, thus antedating the operations of all others as far as we are aware of. If he was not the first to publish a detailed account of the operation, the credit certainly belongs to him of forcibly instructing the profession on this subject, and popularizing the operation. It would seem then that we in our Centennial year, could claim this operation as one of the advances made in the field of American surgery.

172 W. 44th St., May 24, 1876.

ANIMAL HEAT AND ITS REDUCTION BY THE USE OF GELSEMIUM.

By G. H. GRAY, M.D.,

WEST MERIDEN, CONN.

THE cause of animal heat has long been a vexed question, and to my mind is by no means settled even now, despite the researches of modern investigators. In the arts and sciences, we find ourselves constantly going backward, and accepting, as most advanced, theories which have been discarded once or many times in the world's history. Of all attempts to explain animal heat, perhaps the oldest is to day the most correct.

Prior to the middle of the eighteenth century, the most approved doctrine was that of friction, or the action of "vital force," the latter term—itself unexplained—being used to account for all processes dependent upon some occult power at work in the animal economy.

Lavoisier originated the combustion theory, and has still many followers. He called the lungs a stove, and thought that oxygen combines directly with lung tissue. Bernard moved the stove to the tissues, as he discovered them to be warmer than the blood which came from them. Liebig called the blood the stove, and food the fuel. Berthollet, contemporary with Lavoisier, originated the theory that bodily heat is due to molecular as well as chemical changes, but he confined it to the process of hydration, and made only ingesta take an active part in it, instead of extending the activity to the ultimate structure of the body itself.

Marshall says:—"Respiration is therefore the functional source of animal heat, an important use of this function in the economy being to produce such heat." Unfortunately for this theory, the blood is cooler when it leaves the lungs than when it entered them, by one-third of a degree or more, although oxygen has been taken up and carbonic acid given off.

Dutrochet, indeed, quite overthrew the combustion theory, by his discovery that the vital heat of vegetables is greatest when oxygen is being exhaled, the opposite process being absolutely essential to combustion.

Dalton, after discussing the older theories and showing their unsoundness, gives us one quite as unsatisfactory, namely, that it "depends upon changes of a chemical nature, and is so far to be regarded as a chemical phenomenon." Marshall and Dalton sum up the subject of animal heat in very much the same manner, the former remarking:—"In the animal kingdom, considered generally, we observe that a high temperature of the body increases the activity of the various functions," and the latter saying:—"An elevation of temperature is accompanied by an increased activity of all the nutritive processes."

For my own part, I would transpose these two assertions, formulating the principle thus: an increase or diminution of the activity of the vital functions, is accompanied by a corresponding rise or fall of the temperature of the body; and there we have what seems to me a full and rational theory of animal heat.

The countless myriads of minute cells of which our bodies are made up, are constantly changing; change means motion, and motion means heat. Mr. Newport found that upon the interior of a hive full of quiet bees, the mercury of the thermometer stood at 48.5°, but when the community became excited by his rapping upon the hive, the temperature, as shown by the same thermometer, rose to 102°. Instances are too common of the correlation of motion and heat to require any proof; every child is familiar with them; so I will spend no time upon that point, except to call attention to the same argument used by the champions of combustion; *e. g.* Why should not a simple process like this be attended by the same results inside the body as outside it?

Of the very many facts and arguments which might be urged in defence of this view of the subject, I select only a few of the simplest and most common.

Berthollet's theory is criticised because it does not explain the higher temperature of animals which consume large quantities of carbon and hydrogen in their food, but it will hardly be disputed that all through the animal kingdom, the activity of the animal and the temperature of the body hold a definite unvarying relation to each other, from the lazy toad with his temperature of 51.6°, to the swallow whose rapid movements the eye can scarcely follow, and which thrives upon a temperature of 111.25°. The more active the animal, the higher his normal temperature: this theorem of course referring to species, and not to be confined to individuals where there may be exceptions.

We are familiar with the fact that exercise increases the temperature of a part or the whole of the body. The stage-driver transforms motion into warmth by striking his hands against each other, which is but a homely and practical illustration of Helmholtz's theory of solar heat. We stamp our feet when they are chilled, and we know that the coldest bodies—

even ice—rubbed together show an appreciable rise of temperature.

In the same manner as exercise of the muscles warms the parts of the body thus moved, the temperature of the brain is increased by thought or mental activity, and the blood itself varies in temperature in different parts of the system; as Claude Bernard found in the living dog, the blood of the abdominal aorta varied from 90.5° to 105.6°; of the portal vein from 100° to 106°; and of the hepatic vein from 101° to 106.8°. And when we come to examine the results of Bernard's experiments, as given above, we find just what we might reasonably expect. The aorta receives the blood directly from the heart, is a very large vessel, and probably hardly one blood globule in a million comes directly in contact with the *tunica intima*, hence a comparatively low temperature; but the blood of the portal vein has first been forced through capillaries, where every globule has rubbed against the lining coat of the vessel, and has come into somewhat violent contact with its fellows, the consequence being an increased heat, and before it has had time to recover from the effect of passing through the capillaries of the intestines, it is again propelled through a still finer network in the liver, from which it emerges by the hepatic veins, warmer than anywhere else in the body. Thus we find everywhere, activity and forcible contact increasing temperature, which takes us back to the seventeenth century, when physiologists explained animal heat by "friction and vital force."

Thus far we have been studying the normal heat of the living body, that of man being estimated at about 100° Farenheit; though a variation of 20° below and 13° above habitual temperature being compatible with a continuance of vital functions, while outside those limits vitality ceases and death ensues.

The existence of a definite amount of heat in the human body once granted, it is a self-evident proposition that, in such a delicate and complex structure, any deviation from the absolutely correct and physiologically proper mode of living, will be followed by a corresponding deviation from the normal condition of the various organs which make up the body, and consequently also in the products and influence of these organs.

We have seen how animal heat may be produced; the constant changes that are going on in the system being regulated and proportioned to each other so carefully, that the balance is perfect; and while such is the case we enjoy health or ease. But the physician has to do with disease, and in this state, whatever its cause, pre-eminent among symptoms stand variations from the normal temperature.

We are all familiar with a group of symptoms consisting of rigors, followed by increased heat of skin, quick pulse, languor, and lassitude, and to such, from ancient and honorable custom, we apply the term fever. For our present purpose it is sufficient to define this term as *abnormal heat of the body*.

Dunglison gives nearly two hundred varieties of fever, dividing them into two great classes; idiopathic or essential, and symptomatic. Almost every one who has written upon the subject has attempted to give a more comprehensive definition of the word than those who have preceded him, and the criticism of my definition would doubtless be, that it deals with but one of the group of phenomena which make up the condition thus designated.

But I believe all fevers—so-called—to be one and the same thing, save in their complications. To be sure, there is apparently a wide difference between variola with its pustular eruption, scarlatina with its sore throat, phrenitis with its delirium, intermittent with its three distinctive stages, and typhoid with its regular thermometric variations and intestinal complication. But the thermometer shows one condition common to all—an increase of temperature—and this seems to be the essential requisite for the name fever.

There is evidently some cause, ever ready to act, liable to assert itself in the most varied diseases, which produces this heat. That it is to some extent independent of the disease it accompanies, is shown by the fact that it rises and falls, with great regularity sometimes, as in typhoid fever, and in other diseases without any apparent system, and again may remain affected but little during the whole course of a malady. We can readily see how it may be *connected*, accidentally, as a cause, or as a result, with local irritation in any or every organ of the body, and so produce the multiform varieties which have in common the surname fever. But what *produces* an increase of heat? Undoubtedly irritation; this, according to Broussais, meaning "the condition of an organ, the excitation of which is carried to so high a degree, that the equilibrium resulting from the balance of all the functions is broken," or more simply, "excess of vital action." The results of irritation may be as diverse as are the morbid influences and their manner of application. In typhoid fever we have a specific poison which acts as an irritant locally, to a great degree, though having a secondary general effect. This general hyperactivity can be reduced by the drug about to be mentioned, but it is likely to recur unless the cause of the local trouble is eradicated.

Incise the skin of a living being, and the incision is followed by increased molecular activity, resulting in increased heat, redness, swelling, pain, &c., which group of phenomena we denominate inflammation. This is from *local* irritation.

Again, some poison or irritant finds its way into the blood, and through the blood into the general system. An increase of molecular activity results all through the system, resulting in increase of heat, pain, redness and swelling—that is, the headache, flushing and eruption—and that group of phenomena we call fever.

Dr. Lionel Beale, in his Lumleian lectures last year, in speaking on Life and Vital Action, says, "Fever is simply a general inflammation," and by an entirely different route we have arrived at the same statement.

To sum up then:

First. Animal heat is due largely, if not altogether, to vital activity, or the changes which are constantly being wrought in every part of the body.

Second. Fever is the perversion of a normal process or the hyperactivity of vital functions, and is due to local or general irritation.

Abnormal heat of the body has come to be regarded as somewhat independent of the diseases with which it is associated; for, in the fevers marked by a very high temperature, this single symptom receives more attention than any other; and that with the view of simply modifying the heat, not with any expectation of reaching the seat of the disease. Thus, the affusion and the wet pack in scarlatina, and the various expedients for overcoming the opposite condition in the cold stage of cholera and diphtheria, are directed toward bringing back a healthful temperature.

The poison of intermittent fever is eradicated by quinia, that of variola and some other zymotic diseases by the hyposulphites, syphilis by mercury and potassium; that is, these drugs exert an influence over the local or general irritating cause, but not upon the

secondary general excitement; this has to be met by what we term antipyretics.

If my theory be correct, this class of medicines act by restraining molecular activity, either directly through the blood, or indirectly by acting first upon the nervous centres.

If we had a single drug, upon which we could rely, to search out from all its accessories the active cause of abnormal heat, and put a stop to its action, we should think ourselves fortunate, and we would indeed possess an invaluable weapon of warfare against disease. That we have at our command such a drug in gelsemium, I fully believe, and after using it in every possible case for more than a year past, I am satisfied of its power to control the temperature of the body, without being either dangerous or hurtful in any way, if used intelligently and carefully. I have given it in the severe fevers incident to teething in very young children, in surgical fevers, typhoid, scarlatina, pleurisy; in fact, in every case which has come under my observation for some time past, where there has been a rise of temperature above that of health; and in not a single case has it disappointed my expectations of reducing heat and promoting comfort; and as I give it in very minute doses, I have never seen any of the reported ill effects upon the heart or nerves.

Gelsemium is prepared from the root of the *G. Sempervirens* or Yellow Jessamine, a beautiful climbing plant indigenous in our Southern States. Our Dispensatory has but a very brief and unsatisfactory account of it, and that little taken from the Eclectic Dispensatory.

The virtues of the root were discovered by accident: a planter of Mississippi, while suffering from an attack of bilious fever, sent a servant to gather a particular root, and directed him to make an infusion of it. The servant by mistake gathered the root of the wild Jessamine or woodbine, prepared the infusion, and presented it to the master. The effect was most alarming, and the friends gathered around expecting every breath would be his last; but to their surprise, as well as his own, he recovered, and not only that, but discovered that every vestige of fever had disappeared.

Thus brought to light, the plant was used secretly for a long time, was a few years ago admitted to the Dispensatory of the Eclectics, and has now a place on the secondary list of our Pharmacopœia.

There have been several articles written about it within a year or two, both here and in Europe, most of them denouncing it as uncertain and dangerous in its action; and several physicians with whom I have talked about it speak in a like disparaging manner, asserting that it disorders vision, prostrates the nervous system beyond the possibility of reaction, and can never be relied upon to effect just the object desired.

It has, like most everything else, had its devotees, who have claimed for it all possible virtues and powers. Carried to its fullest effects, it seems to relax the muscular system, with the exception of the uterus, which it acts upon like ergot, only more mildly; it has a peculiar and constant effect upon the third nerve, and as a febrifuge is unrivalled.

The latter is the only action of which I have made a special study; and, as I said before, I have never been disappointed in it as an agent for reducing temperature. A few cases will illustrate.

I was called to see a child one evening who had been listless, constipated, without appetite, complaining of headache and thirst for nearly a week. Was in bed, with a coated tongue, very hot, dry, and rough skin, flushed face, pulse 147, respiration over 40, and temperature 104.6°. I prepared a mixture consisting of ten drops tinct. gelsem.; ten grains potass. bromid.; and water half a small tumblerful, directing the mother to give a teaspoonful every hour, and afterward every two hours, until the fever began to subside, headache was relieved, and free perspiration had appeared. This was about eight o'clock in the evening. I called the next morning at nine o'clock—thirteen hours after—and found the child playing out of doors. The bowels were constipated for four days, but with this exception there was not a sign left of any disturbance; and even the bowel trouble, which I then attributed to the gelsemium, I concluded from subsequent observations was due to some other cause.

A severe case of typhoid fever, which occurred in my practice last summer, was treated with the same drug whenever there was a high temperature, with the effect of entirely breaking up the regularity of the morning and evening variations, and all through the third week of the disease keeping the heat below 101°.

A case where Dr. Francis Bacon operated for stricture, doing the perineal section, on the third day rigors set in, followed by the usual surgical fever, the pulse running up to 148, and temperature to 104° and a fraction. About seven o'clock in the evening he began taking the gelsemium, and when I called at nine the next morning, pulse and temperature were nearly normal, the latter not reaching 100°. I have now on hand a case of pleuro-pneumonia, in which between five o'clock in the evening and nine the next morning, the thermometer showed a reduction of the heat from 104.2° to 101.5°, due to the use of the same drug.

But perhaps the most remarkable case of late was one of scarlatina, which Dr. Catlin, of Meriden, saw with me. Between five o'clock in the evening, when I first saw the case, and nine the next day, when Dr. Catlin saw it with me, the temperature was reduced from 105° to 99.2; and during the whole disease, which lasted acutely only six days, the temperature never rose above 102°, except for a half day, when the gelsemium was stopped by mistake; then it rose to 103°, but was at once reduced to 101.8° by resuming the medicine. My usual prescription for a child less than five years old is:

℞ Tinct. gelsemium.....gtt.xx.
Potassii bromidi.....ʒi.
Aquæ.....ʒiv.—M.

Teaspoonful every hour until fever begins to abate; then every two hours, until free perspiration is produced.

For children from five to fourteen or fifteen, I give in four ounces of water half a fluid drachm of the gelsemium and thirty grains of the bromide. For adults, a fluid drachm of the tincture, and a drachm of the bromide, to four ounces water, with the same directions for taking.

It will be seen that the dose for a child is only about ⅛ of a drop, and the adult dose not two drops; and I think, as the full effects are obtained by these small, frequent doses, the complaints that are made against the drug arise from too large doses. At all events, the effects above related are sufficient to claim for gelsemium the attention of all who wish to avail themselves of the best means of combating fever; and, if every one has as good success with it as I have had, there will be but little fault found with it.

Lest some of the champions of bromide of potassium should say the above effects were due to that, instead of the gelsemium, I will state that for some time I used the latter alone, with quite the same effect upon the temperature, and combined the two for the quieting effect of the salt, gelsemium not producing very marked results of that sort in such minute doses.

Progress of Medical Science.

ANGINA LUDOVICI.—Mr. A. Doig reports several cases amongst the soldiers quartered in the South Camp, Aldershott, during the winter of 1874-75. They all presented the same symptoms as the cases reported some time ago by Dr. Murchison (RECORD, Feb. 26, 1876), but suppuration occurred in quite a number, and the following case ended fatally. The patient was 22 years old, and when first seen presented the usual symptoms. The submaxillary, sublingual and parotid glands were swollen and very hard. The swelling increased, and never lost its hard character; the skin became œdematous, and the breathing was very difficult. Incisions were made under the tongue and externally, but no matter escaped, and on the fourth day death ensued. Forty-three hours after death an examination was made, and a large swelling occupied the neck, chiefly on the left side, but extending somewhat to the right and down about midway between the lower jaw and clavicle. On removing the skin over the swelling, the tissues were found in a gangrenous state, being filled with a brownish-colored, very fetid, semi-fluid matter. All the tissues, including glands and muscles, were involved. The portion of the lower jaw in contact with the diseased glands was denuded of periosteum. The larynx was surrounded by the morbid mass, but the tissues posterior to the pharynx were not involved. The mucous membrane of the fauces, that covering the epiglottis, and the whole of the larynx were in an œdematous state. The lungs were deeply congested and contained hemorrhagic infarctions, and the lung tissue around contained numerous small deposits of tubercle. Both right and left cavities of the heart were filled with clots partly decolorized. The other organs were found to be in a normal condition.—*The British Medical Journal*, April 15, 1876.

TREATMENT OF TETANUS.—Dr. Leonard Cane reports the case of a man, 28 years of age, who had injured the great toe of his right foot by letting a heavy weight fall upon it. No really unfavorable effects occurred till three weeks after, when he was seen by Dr. C. He then complained of severe pains in his right toe, followed by cramps in the foot and ankle, with convulsive twitchings of the leg. The respiration at the same time was affected, and almost stopped during the paroxysms. Twenty grains of chloral were administered, and in two hours a similar amount given, when the patient became quieter and at last fell asleep. During sleep there were some slight twitchings. The following day there were still pain and cramp, and the chloral was given every four hours during the day, and by evening the spasmodic movements were very slight, and occurred at long intervals. The next day the cramp had nearly disappeared. Bromide of potassium ten grains, in combination with compound tincture of gentian one drachm at a dose, was given three times daily, and recovery was soon complete. Mr. G. W. Callender speaks highly of nerve-stretching in tetanus. Recently Verneuil, in a severe case of crushing of the hand, causing tetanus, exposed the median nerve at the elbow and the ulnar at the wrist, and used traction upon them. The recovery was complete. Mr. C. says the operation is not severe, and after the nerve is freed from its surroundings it is stretched with an ordinary vulsellum. The generally unsatisfactory results of the present treatment of traumatic tetanus, in his opinion, fully justifies the performance of the operation.—*The Lancet*, April 15 and 22, 1876.

EXCRETION OF BLUE URINE.—M. Ramondède reported to the *Société Anatomique*, on January 14, a case of gangrene of the mouth with interstitial nephritis, in which the urine had contained indican during the entire course of the disease. The autopsy showed commencing interstitial nephritis; the tissues of the kidney were blanched; the vessels, especially the veins, were surrounded by newly-formed connective tissue, and there were some ecchymoses. The spleen was the seat of multiple infarctions.

M. Robin called attention to the fact that the blue matter was not the same in all cases of blue urine. Neither M. Gubler nor himself had ever found the urine to contain indigo. Indican should not be confounded with indigo; it is produced by the action of oxidizing agents that destroy indigo. He referred to a case, formerly reported by him, in which the blue color of the urine was due to the presence of cyanurine. This cyanurine is a substance intermediate between urea and uric acid.—*Le Progrès Médicale*, April 22, 1876.

ALBUMINURIA PRODUCED IN CHILDREN BY THE TINCTURE OF IODINE.—At a meeting of the *Société Medicale des Hôpitaux*, on April 28th, M. Jules Simon stated that he had been treating tinea favosa in children by painting with a mixture of equal parts of tincture of iodine and glycerine. On April 4th, he applied this mixture to a little girl, without previous washing or epilation. It was noticed soon after that the child presented peculiar symptoms, and that the face had assumed a reddish purple color; and on examining the urine, the presence of both iodine and albumen was discovered. The urine of eleven children treated in the same way was examined, and in all found to contain iodine, and, in four out of the eleven, albumen. The albumen disappeared when the iodine treatment was stopped, and reappeared when it was recommenced. In two cases iodism was produced. The favus was cured about as readily as by other methods of treatment. The iodine was only applied to cases of pure favus without eczema or impetigo.

M. Dumontpallier said that he often treated diabetes by large doses of iodine tincture internally, and that he had never found albumen in the urine in those cases.

M. Jules Simon said that there was question here of children, and not of adults. He had found iodine but not albumen in the urine when iodide of potassium was being taken.

M. Archambault said that albumen is often present in the urine of young scrofulous and rachitic children, and asked if it were certain that the iodine produced the albuminuria in the above cases. M. Isambert stated that tincture of iodine in doses of four to twenty drops is given in some cases of chronic albuminuria, and that it reduces the amount of albumen.—*La France Medicale*, May 3d.

ADMINISTRATION OF SALICYLIC ACID. In view of the many therapeutic uses of salicylic acid, it has become important to find a menstruum that will dissolve it in sufficient quantity. The ordinary solution in some alcoholic vehicle contains so much alcohol, that it cannot be given to children or to women; while, on the other hand, the caustic character of the acid prevents its administration in suspension in a

mucilaginous fluid. M. Cassan, of Paris, believes that he has found the desired solvent in citrate of ammonia. While thirty grains of salicylic acid require an ounce to an ounce and a half of rum or cognac alone to dissolve them, if fifteen grains of citrate of ammonia be added to the acid, only two drachms of the spirit will be required to make the solution. The citrate of ammonia gives no unpleasant taste to the fluid. The following formulæ may be employed:

℞. Acidi salicylici, ʒ i.; ammon. citrat., ʒ ss.; spirit. vini Gallici, ℥ i.; aquæ destil., ℥ v. Or, for a single potion. ℞. Acidi salicyl., grs. xv.; ammon. citrat., ʒ ss.; syrupi simp., ℥ i.; aquæ destil., ℥ iv.—*Bulletin Général de Thérapeutique*, April 30.

A New Antiseptic.—A curious fact, interesting on account of its bearing on public and private hygiene, has been observed and reported by M. de Rostaing. A piece of meat, placed in a vessel containing powdered madder root, on the 27th of July, 1875, was found on February 27th, 1876, to be in a state of perfect preservation. It had not the slightest odor, and there had been no development of living organisms. This fact proved, he thought, the antiseptic qualities of the madder root, and M. de Rostaing suggests that it may be utilized in the preservation of cadavers and in improving the hygienic condition of cemeteries. A committee has been appointed by the *Académie des Sciences* to investigate the subject. —*La Tribune Médicale*, April 30.

Aniline Poisoning.—M. Laboulbène exhibited to the *Société Médicale des Hôpitaux*, on March 24th, a workman from a factory where the colors derived from aniline are made, who presented a marked and permanent amaranthine discoloration of the hands, feet, and hair. This discoloration made its appearance since he began to work near the vats, whence acrid aniline fumes, which were irritating to the eyes, escaped. Two months later he began to complain of pains in the penis and scrotum, and these parts became swollen, and have remained so since. One month after these symptoms appeared, he began to suffer from vertigo, loss of sexual power, and bitter taste in his mouth; but nevertheless his general health continued good, and he was not anæmic. There were no symptoms of arsenical poisoning, although arsenic was used in the manufacture of fuchsine.

M. Bergeron stated that he had seen several cases of aniline poisoning in which the skin and mucous membranes were discolored as in M. Laboulbène's case, but he had never seen œdema of the scrotum except in profoundly anæmic patients. The fumes of aniline, which are produced in great quantity at the moment of its transformation into fuchsine, cause vertigo, hebetude, weakness, somnolence, sometimes even epileptiform attacks, tetanic spasms, etc. In the end, the workmen fall into a condition of profound anæmia, with discoloration of the skin, lilac tint of the lips, anorexia, gastric disturbances, etc.; but this state of affairs is promptly corrected by respiration of pure air, or by inhalations of oxygen, and the use of evacuants.—*Gazette Hebdom.*, April 14th, 1876.

Spontaneous Abortion in the Early Months of Pregnancy.—Dr. Leblond, who has been studying this subject in its medico-legal aspect, gives in a small pamphlet the histories of eleven unprovoked abortions, in none of which the membranes were ruptured. He then quotes from several authors, who hold that in spontaneous abortions in the early months of pregnancy, as a rule, the embryo and its membranes are passed entire, and that rupture of the membranes is presumptive proof of a criminal abortion. In concluding, he sums up as follows:

1. When the embryo is contained in healthy and unbroken membranes, it is most probable that the abortion was spontaneous, unless it had been excited by means that cause expulsion of the egg without affecting its walls.

2. When the membranes are ruptured, but still healthy, it is probable that the abortion was provoked.

3. When the membranes present pathological alterations, no certain conclusions can be drawn from an examination of the expelled mass, but still it is probable that the abortion was the consequence of some primary disease of the embryo.

Syphilitic Arthropathies.—M. Voisin has just published a very interesting work, entitled *Contribution à l'Etude des Arthropathies Syphilitiques*, from which the following conclusions may be drawn:

1. Arthropathies exist in all the stages of syphilis.

2. In the primary period there are vague, multiple pains, to which the name of arthralgies is given.

3. In the secondary period these pains recur, but there are also inflammatory phenomena in various joints. These arthropathies resemble either a subacute arthritis, or a simple hydrarthrosis.

4. In the tertiary period they are chronic and resemble white swellings.

5. These arthropathies disappear under the influence of specific treatment.—*La France Médicale*, April 22d.

Extraction of a Living Insect from the Ear.—The *Archives Médicales Belges* relates the following case: A little girl, three years old, put an insect, '*bête à bon Dieu*,' into her ear. Sharp cries, agitation, convulsive symptoms, ensued: injections of water were made without result. The physician then conceived the idea of asphyxiating the insect by means of chloroform: he dropped four drops of chloroform upon a small piece of cotton which he introduced into the ear. Immediately the child ceased crying, and complained no further of any disagreeable sensation; the insect had become asphyxiated; an injection of warm water brought it away dead, and no further trouble ensued. *Dublin Med. Press & Circular.*

Treatment of Obesity by the Waters of Brides.—According to Dr. Philbert the waters of Brides in Savoy, which are very similar to those of Carlsbad, are very useful in the treatment of obesity. The purgative salts contained in these waters are sulphate of soda, chloride of sodium, chloride of magnesium, sulphate of magnesia, and sulphate of lime. To increase the effect, from 15 to 80 grs. of sulphate of soda are added to each glass of mineral water. The quantity taken daily is one litre, divided into three doses, and the purgative effect is produced in two or three days. The course may last from four to six weeks. As an adjuvant to the waters, a vapor bath may be taken every day or every second day. Farinaceous and saccharine articles of food are not allowed, and brandy, liqueurs, and coffee are interdicted; but the quantity of food is not limited, and a moderate amount of wine may be taken without harm. Muscular exercise is considered indispensable, and the mountains in the vicinity of Brides afford every facility for walking, where, in addition, this treatment may be followed by the grape cure.—*Journal de Méd. et de Chir.*, April, 1876.

Cautery in Treatment of Pedicle in Ovariotomy.—Mr. Thomas Keith reports the use of the actual cautery in 50 cases. The result was 92 per cent. recoveries, the best he has yet had.—*Lancet*, April 15, 1876.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, June 10, 1876.

THE SHORT-TERM SYSTEM.

In referring to our recent editorial upon the short-term system in Louisville, Dr. Gaillard makes the following remarks: "It was stated in this Journal (*American Medical Weekly*) that the recent publications of the RECORD 'are surprising blunders,' and this statement is repeated. It was believed at the time that the blunders indicated were unintentional; but this belief is now impossible, as Dr. Shrady, the editor of the RECORD, without a shadow of proof for what he has published and still publishes, 'is not sorry that he conveyed such an impression, as he intended to do so.' Whether the publication of injurious or even libellous statements, without a shadow of proof for their correctness, will, in the estimation of the profession, injure the parties libelled or the vehicle of the libel, each reader can judge for himself. If Dr. Shrady can prove his statements to be true, these statements and hims lf will receive the most courteous consideration. So far, there has been only assertion unfounded, and not sustained by a particle of proof. Dr. Shrady believes 'that such a state of things as graduating a student in nine months does exist in Louisville,' and therefore regards it as a 'monstrous evil.' The public have a right to the evidence justifying such a belief, before hesitating to condemn the use of epithets in regard to an evil whose existence is simply assumed."

We are not a little surprised, in view of the efforts which Dr. Gaillard has made to defend the short-term system, that its existence as a matter of fact should be questioned by him. When Dr. R. O. Cowling, the editor of the *Louisville Medical News*, exposed the affairs connected with the Louisville Medical College and the Kentucky School of Medicine, we were at first disposed to doubt the accuracy of his statements, for the simple reason that they apparently proved too much. Looking upon the controversy as one of the ordinary methods used for increasing the patronage of their respective schools, we were not disposed to give it the serious consideration which we afterwards found it in reality deserved. Being repeatedly challenged for an opinion in regard to the merits of the case, we were compelled to examine the evidence on both sides, and were forced to believe that all the conditions necessary for the graduation of a student in nine months from the time of the actual commencement of his studies, did really exist in Louisville.

As we have no desire for anything but the truth in the matter, we gladly give the facts upon which our statements in regard to the short-term system are founded. In order to understand the questions at issue in all their different bearings, it is necessary to know that the Louisville Medical College gives a winter course of five months, and the Kentucky School of Medicine gives a summer course of four months. Both of these colleges have virtually the same faculty, have the same dean, and are evidently in direct partnership. It is true they have different charters and different boards of regents, but their interests are common, and, practically speaking, they count as one school, with a session of nine months. Each school is vested with the legal right of granting degrees in medicine; and, as the graduate of one school receives the *ad eundem* degree of the other, it is not very difficult to understand that not only one but two diplomas can be obtained in nine months. In the face of this fact, which is published in their annual announcements, we are given to understand that the schools are entirely different institutions, and the circumstance of having a faculty in common is merely accidental.

We have been led to believe that this faculty favored the short-term system, by the following advertisement:

"Students entering the Kentucky School of Medicine in March of each year, after their winter session is terminated, will enjoy a continuous course of instruction of from nine to ten months, and can graduate at the end of the term. Again, students desiring to study medicine, instead of being compelled to wait until autumn, can enter upon their first course in the Kentucky School of Medicine, and will thus, in the succeeding year, enter medical colleges, not as first-course students, but as candidates for graduation, *gaining thus a year in their professional life.** (*Annual Announcement of Kentucky School of Medicine, Session* 1876.)

The Louisville Medical College, which, we are told, is "an entirely different institution," publishes, in its announcement, the following:

"*Important Notice.*—The attention of medical students is particularly directed to the fact that all who attend their first course of lectures in the Louisville Medical College (which closes in the last week in February) can commence their second course of lec-

* The italics are ours.

tures in the Kentucky School of Medicine in the first week of March of the same year. . . . . *Students adopting this plan will save nearly a year of professional life;** graduating in June, instead of losing the summer and graduating in March of a subsequent year."—(*Announcement Louisville Med. Coll., Session* 1875–76.)

It must be recollected that the combined courses of these colleges represent a period of but nine months; and, as inducement for the student to patronize both schools, and take what is nothing more than a nine months' continuous course, he is told that he will save a whole year in study, and will receive two diplomas besides. In view of these facts, we are led to believe "that such a state of things as graduating a student in nine months does exist in Louisville," and we confess that the explanations which Dr. Gaillard has offered have not shaken us in this belief.

The facts which we have stated are duly published by authority of the faculty, and we labored under the delusion that they were not to be questioned. In connection with this nine-month system, it is proper to state that neither of these schools insist upon any extra period of study for those students who may present themselves for graduation. As far as time is concerned, the candidate is merely required to attend two full courses of lectures at these different (?) institutions. The only exception to this provision is, that four years of reputable practice succeeding a regular course of study will be deemed equivalent to a first course of lectures. The inconsistency of the latter regulation is quite apparent, in connection with the disposition on the part of Dr. Gaillard to ignore any definite time beyond nine months as a necessary factor in the acquirement of a medical education. If time of study is of no account, why insist upon it at all? The only conclusion to be drawn is, that a young man who has faithfully studied medicine under a doctor of medicine, but outside of a medical college, and afterwards practised his profession for four years, has certainly lost so many years of his professional life, less the five months which might have been consumed in attending a first course. We admit this as a good argument in favor of the short-time system and its attendant advantages of double diplomas.

So far, we believe, we have proved that the colleges in question offer facilities for shortening the time of study, and that they do not insist, with the exception named, upon any extra period than that consumed in their two courses. If the faculties (we use the plural as an act of courtesy to the different boards of regents) actually insist upon any more time being consumed in the study of medicine than we have named, we should like to have them say so. The burden of proof in this matter rests with them, not with us. We freely admit that their graduates *may* study one or two years before entering the colleges, but the question for Dr. Gaillard and the faculty to answer is: Do they? If this be a rule to which there has been found no exception, we confess to the belief that such a state of things as graduating a student after merely nine months' course of study, does *not* exist in Louisville. Throughout the whole discussion upon the subject, we have noticed nothing which might be construed into a direct and satisfactory answer of this question; but, on the contrary, a constant attempt is made to bring in side issues, behind which the real truth appears to be hidden. The effort to excuse the short-term system by reference to similar doings in other colleges, is another element in the controversy which does not tend to convince us that our belief is unfounded. The establishment of a bad precedent is not the vindication of a good principle.

If the colleges in question do conscientiously insist upon the full term of study as required by the leading medical institutions of the country, they certainly give a very erroneous impression to the student. The labored endeavor to show that qualification alone should be the test for graduation, creates the unwelcome suspicion in our mind that shortening the time of study is aimed at; and this suspicion gives place to a firm conviction that such is actually the case, by a promise, on the part of the faculty, to save a year of professional life to the student.

Assuming, in the absence of positive proof to the contrary, and in view of an impartial interpretation of the facts already before us, that no extra time of study was required, we glance over the list of graduates of the Kentucky School of Medicine, of the class of '75. (Spring Course.) Of the 42 graduates named, 24 took a continuous course of nine months. This fact shows merely the possibility of students graduating within nine months, as we have no record of their having attended any previous course. The possibility in the case of the 24 is strengthened into a certainty with eight others of the 42. The eight named graduated in June, after having completed their *first* course the previous March in the University of Louisville. We make this statement on the highest possible authority, and are willing to give the names of such graduates to the dean of the faculty of the Kentucky School of Medicine, if he desires them.

As the colleges in question have given us no reason why they should not graduate these gentlemen at the end of nine months' study, we would ask how many of the 42 graduates have actually studied medicine for a longer period. If all of them have fulfilled the usual requirements as to time, then we are ready to confess that we have made a "surprising blunder" in believing it possible to graduate any one in Louisville in nine months.

Dr. Gaillard speaks strongly of qualification as the real test for graduation. What does this qualification amount to? A mere faculty examination is of very little account. It is quite generally acknowledged

* The italics are ours.

that such examinations are wholly untrustworthy. Unless these colleges have a different method of conducting their examinations, and exact a higher standard than any of the schools in New York or Philadelphia, the profession will be very slow to believe that their means of judging of qualifications are any better. In fact our critic virtually admits that they are of no real or practical value by advocating examinations by impartial boards. In view of the impossibility of deciding upon qualifications by an examination of ten or fifteen minutes in each branch, the leading colleges have agreed to insist upon a reasonable time for study, and have fixed this period at three years. The real value of a college course compared with outside study is in proportion to the extra facilities for systematic instruction and clinical demonstration which are offered by the faculty. If a double college course can be considered complete in nine months, either the faculties have discovered some improved plan of teaching, or college instruction strictly so called amounts to very little. We contend that time for study has such a direct bearing upon the amount of qualification, that they cannot be separated. Medicine is a science which must be mastered step by step, by hard and steady work. The longer the period spent in this work, the better the qualification in the end. Substantial growth means time. While we always admire the strength, durability, and magnificence of the oak as an exponent of this principle of growth, we are ever ready to smile in pity at the poor mushroom whose lively exuberance could be expended in no better way than by giving it a double head.

We are not surprised that considerable interest should be manifested in the discussion of the short-term system, by parties not only in, but out of the profession. The editor of the *New York Times*, with a very commendable show of good feeling towards the medical colleges, finds it difficult to believe our statement in regard to the possibility of shortening the time of medical study. In view of his reply to our recent editorials upon the subject we are inclined to give more credit to his heart than to his head. His spirited vindication of the good intentions of the great majority of the medical colleges, not only commends him to the respect and esteem of the medical profession, but to the charitable consideration of his methods of argument. The best that can be said for the latter, is that they are ingenious. In order to prove that we are wrong in supposing that the time of medical study can be shortened, we are informed that the regular terms in the great majority of the schools is three years, and that the *Editor* of the *N. Y. Times* has inquired about "*some* of the schools referred to," and finds "from reliable sources that not one student ever obtained a degree in these institutions, who had not fulfilled the law, so far as completing the three years' course of study and attending the two full courses were concerned." After the statement of these facts, which never were disputed, he staggers us with the following remarkable conclusion:—"It follows, then, that medical colleges which, in the graduating of students are honestly and faithfully guided by the law laid down in their charters, are not only free from corruption, but justified in the exercise of rights which the profession and the public—including the editor of the RECORD—are bound to respect." If the text is the short-term system, our preacher has tacked it to the wrong sermon. Further on, in speaking of the legal requirements of a medical education, he says: "In the face of these facts, the editor of the RECORD charges them with corruption for doing simply what they are obliged to do, and cannot avoid doing if they would." To prove how we can make a charge against regular courses of three years when "the burden of the complaint" is against the "outside schools" that "*shorten the period of study*," will probably give the *Times* another opportunity for the ventilation of its logic. That "some" of the schools comply with the law is not the strongest kind of argument to prove that all must.

We perfectly agree with the editor of the *Times* and with Dr. Gaillard in the belief that this and all other evils connected with imperfect medical education can be effectually remedied by a proper and impartial final examination. The services of these writers in the attempt to prove to us the necessity for State boards of examination are, in view of the principles which we have been advocating for years, somewhat gratuitous, if not presumptuous. We are willing, however, that they should take some credit to themselves for offering apparently original ideas.

Reviews and Notices of Books.

VITAL MOTION AS A MEANS OF PHYSICAL MOTION. By CHARLES BLAND RADCLIFFE, M.D., etc. London: Macmillan & Co. 1876.

THIS volume with a new title contains the facts and theories which for some twenty-five years have been laid before the public by Dr. Radcliffe, concerning the phenomena of contraction, of nerve force, etc. The same facts, minus some additions, were used by the Doctor to explain what epilepsy, spasm, and pain are. It is well known by this time that, unlike most physiologists, Dr. Radcliffe, with the late Drs. West, Dugès, Matteucci, Stannius and a few others, regards contraction as the normal state of the muscular fibre. He contends that the nerves do not bring on contraction of muscles on being stimulated, but that their influence simply counteracts it. When the influence of the nerve is inhibited, *i.e.* taken away, then the muscles, following the law of elasticity, contract. The muscular fibre, according to him, must be considered as Leyden jars, always charged. The charge is brought on by nutrition; the nerves are the instruments which cause the discharge.

Those facts are contradictory to what is now accepted in physiological science, viz., that muscles are

relaxed in their normal state when they are separated from their nerve. It is not easy to reconcile the theory of Dr. Radcliffe with the facts as they are daily observed. The physiologists all have seen that when the spinal cord or a nerve is cut across, the muscular mass which receives nerve supply from the part separated instantly becomes relaxed. This state, according to Dr. Radcliffe, is not one of paralysis, but simply of activity; it is due to the influence of the nerve centres upon the muscular fibres. Accordingly, therefore, in every case of what we are content to call paralysis, section of nerve, of spinal cord, through disease or otherwise, we ought to have contracture. Certainly enough, such a state does sometimes exist; in cases, for instance, of contracture of certain muscles of the face on the paralyzed side after cerebral hemorrhage. But these and other facts are susceptible of another explanation, less paradoxical at any rate; for in those instances, the centres of the nerves directly implicated are not the seats of the disease. They undergo some morbid irritative influence in the shape of sequelæ of the original disease of the hemisphere.

The facts upon which the Doctor grounds his theories are numerous, but they all are more or less known to the student of electro-physiology, so-called, and are only here given with a different interpretation above stated. The author, therefore, is perhaps not justified in stating, in his first chapter, that we are no better than Molière's physician, who was content to know that opium induces sleep because it possesses the "virtus dormitiva." We are content to know that muscles contract because they are endowed with the faculty of contractility. All our aim is to study the phenomena of this fact and discover its laws; we can do no more. Nor has Dr. Radcliffe succeeded in showing us what contractility is. Even if we accepted his theory we would still have to know what elasticity is *in se*, and also the electricity which plays such a rôle in his theory.

The book, like its predecessors, is nicely printed, written in that peculiar happy and suggestive style which Dr. Radcliffe possesses to so high a degree, and well deserves perusal.

Filth-Diseases and their Prevention. By John Simon, M.D., F.R.C.S. Reprinted under the direction of the State Board of Health of Massachusetts. James Campbell. Boston, 1876. Pp. 96.

The above statement indicates at once the nature and the importance of this little book. Written originally as a preface to a volume of reports by the Medical Officer of the Privy Council, England, it is now put forth by the Massachusetts Board of Health, with scarcely an alteration and but one or two additions, and its "careful perusal" strongly urged by the members of this Board over their individual names. The essay has been written for the layman as well as the physician. All technical terms have been translated, and no professional knowledge is required for its comprehension.

Insanity in its Medico-Legal Relations. By A. C. Cowperthwait, A.M., M.D. Philadelphia: J. M. Stoddart & Co., No. 733 Chestnut St. 1876.

In this monograph we have a very clever compilation of the views held by Bucknill, Ray, Maudsley, Hammond, Griesinger and others, concerning insanity. It is, in fact, a well-written lecture, although incomplete, and might with propriety be delivered before a body of medical men, lawyers, or a class of medical students. It is made up largely of quotations from the authors already named. For example, the classifications given are those of Esquirol and Hammond; the pathology is that adopted by Maudsley, and taken from German authorities; the chapter on diagnosis is such as any medical man of moderate ability might write, assisted by Bucknill and Maudsley; the chapter devoted to "criminal responsibility of insane" is made up of extracts from decisions and histories given in cases that have passed through the courts in this country and England, and is accompanied with comments made by Maudsley. The chapter on epileptic insanity is a condensed statement of the symptoms attending the development of this condition, and in it Ray and Maudsley have a prominent position. The chapter on treatment is only a meagre outline of the subject; the question of prognosis is ignored; etiology has received no distinct recognition; and semeiology has received only a forced acknowledgment by way of quotations, while giving definitions.

The rules laid down by the author as a guide to the physician who may be called upon to testify as a medical expert, are very good; and, if carefully observed, will doubtless save many a witness from being wounded by a legal poniard. The intention of the writer was good; for, in obedience to the belief that insanity is a symptom of brain disease, and that the responsibility resting upon the medical profession has consequently increased, he has devoted time and study to the production of this little book, in order that he might assist his brethren in a more thorough study of mental diseases.

Reports of Societies.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

CENTENNIAL REMINISCENCES OF AMERICAN MEDICINE—THE FIRST MEDICAL COLLEGE—DRS. RUSH AND SHIPPEN—POST-MORTEM FEES—THE NATIONAL MEDICAL LIBRARY—MEDICAL LEGISLATION—HOMŒOPATHY AND THE HARRISBURG HOSPITAL—PRELIMINARY EDUCATION—OFFICERS ELECT.

This body held its meeting in Philadelphia on Wednesday and Thursday, May 31st and June 1st. The officers were as follows: President, Dr. Crawford Irwin, of Blair County; Vice Presidents, Dr. Andrew Zebinger, of Philadelphia, A. H. Stalberstadt, of Schuylkill, R. L. Sibbett, of Cumberland, J. F. Ross, of Clarion; Corresponding Secretary, Dr. Thomas M. Drysdale, of Philadelphia; Treasurer, Dr. Benjamin Lee, of Philadelphia; Permanent Secretary, Dr. W. B. Atkinson, of Philadelphia; Assistant Secretary, Dr. James Tyson, of Philadelphia. After prayer, the Society was welcomed to the city by Dr. Thomas M. Drysdale, Chairman of the Committee of Arrangements.

He alluded to Philadelphia's association with the early history of medicine in this country, to the difficulties which had to be overcome by the earlier students of medicine, and more especially to the struggles of men who, like Dr. Rush and Dr. Shippen, became eminent as physicians in this city before the Revolutionary war. Benjamin Franklin was president of the first medical college ever established in this country, and in 1769 Dr. Rush was elected to the chair of chemistry in that college. The speaker paid a warm tribute to the memory of Dr. Rush, and spoke of his great services to the people of Philadelphia during the rage of yellow fever in the fall of 1793.

He then reviewed the present condition of American medicine as compared to that of a century ago, and noted specially the present advanced condition of the colleges and hospitals of Philadelphia. It is a fact not generally known that in one of the large apartments of Independence Hall was delivered the introductory lecture on anatomy by Dr. William Shippen, in the autumn of 1762. The number of students who attended this course amounted only to twelve. This was the origin of our medical schools.

Reports were presented from the various county societies, and referred as usual to the Committee of Publication. The Corresponding Secretary then made his annual report, referring particularly to the formation of several new county medical societies since the last meeting, and to the action of the censors of the fourth district in a case of appeal. Drs. Whitmarsh of London, J. W. Voorhies and Joseph Parrish of New Jersey, M. Baker of California, Gruwell of Iowa, and W. B. Mowry of Pennsylvania, were elected members by invitation.

On motion of Dr. S. M. Ross, a committee was appointed to indicate the opinion of the State Society upon the subject of increased fees for post-mortem examination ordered by county authorities, a local county law having fixed the fee at the low amount of ten dollars, when thirty dollars would have been a fairer compensation.

The motion gave rise to considerable discussion, and Drs. Ross, E. A. Wood, and Pollock were appointed the committee.

Dr. Horatio C. Wood offered a resolution, which was adopted, appointing a committee of three [Drs. Wood, Dunglison, and Drysdale] to memorialize the U. S. Senators from Pennsylvania, and to request the county societies to institute such measures as may be necessary to urge the publication of the Subject Catalogue of the National Medical Library upon their representatives in Congress.

Dr. R. L. Sibbett then read the report of the Committee on Medical Legislation, stating that efforts had been made to enforce the law against incompetent practitioners, passed April, 1875; that this was not always practicable; that a judge in Franklin county had decided that the law has only a legal subject and a sanction, without a legal action, and is almost inoperative by reason of unskilful draughting; that additional legislation is necessary; the provisions of a new bill being referred to by him, which was intended to repeal and supplement that of last year. The report concluded with the expressed conviction of the committee, that the Legislature are yet unwilling that any standard of qualification should be fixed by law, in regard to those who shall hereafter commence the study of medicine, or that druggists or apothecaries should be restrained or prevented from giving medical and surgical advice.

In the evening session, Dr. Crawford Irwin, President of the Society, delivered the annual address, which was prefaced by a brief review of the progress of the country in population, &c., since the Declaration of Independence. He then discussed the question of "What is the Province of a Physician or Doctor?" considering it as an occupation, as a profession, and as an office.

On Wednesday morning Dr. R. Davis, of Wilkesbarre, read the Address in Obstetrics, referring especially to the subjects of placenta prævia, the employment of the forceps, etc. After electing Drs. Paine and Lawton of Maine, W. Elmer, Sr. of New Jersey, E. J. Kirksey of Georgia, J. Marion Sims of N. Y., and Kohler of Tenn., members by invitation, Dr. D. Hayes Agnew of Philadelphia read the Address in Surgery, a valuable practical paper on the subject.

On motion of Dr. Rahter of Harrisburg, the State Society listened to a statement of difficulties arising in the Dauphin Co. Medical Society, in connection with the resignation of the medical staff of the Harrisburg Hospital in 1873, which had occurred in consequence of the passage by the managers of the following resolution:

"*Whereas*, It has been stated that if homœopathic medicines be procured, attendance will be furnished gratuitously by a homœopathic physician: therefore,

"*Resolved*, That a case of homœopathic medicines be procured, at a cost not exceeding one hundred dollars, so that if any patients wish to be treated under that system it may be done by a physician of that school."

The Dauphin Co. Med. Society endorsed the course of the medical staff. The State Society passed resolutions sustaining this action; immediately after which Dr. Langfitt of Allegheny introduced a resolution in regard to the graduation of homœopathic students in regular medical colleges; but as this seemed to be a reflection on the course of those institutions, without specific facts being given, the resolutions were tabled. A resolution offered by Dr. Pollock, of Allegheny Co., worded as follows:—"No member of any County Medical Society shall admit into his office a student of medicine, until he presents a certificate from the Examining Committee, testifying that he has been duly examined, and has a good English education, and sufficient knowledge of Latin and Greek to enable him to pursue his studies with advantage,"—was referred to a committee of five, to report at the next meeting of the Society. Drs. Pollock, Stewart, Pursell, Ross, of Altoona; and Miller, of Huntingdon.

The Committee on Nominations then made the following report:—

President—Dr. R. B. Mowry.

Vice Presidents—Drs. George W. Reily, Amos Scip, Thomas Lyon, D. P. Miller.

Corresponding Secretary—Dr. Thomas M. Drysdale.

Permanent Secretary—Dr. Wm. B. Atkinson.

Treasurer—Benjamin Lee.

Recording Secretary—Dr. H. L. Orth.

Committee on Publication—Dr. Wm. B. Atkinson, J. G. Stetler, Benjamin Lee, T. M. Drysdale, James Tyson, Albert Fricke, H. L. Orth.

Delegates to the American Medical Association—Dr. F. C. Harrison, Union; Dr. M. S. Welsh, Vernango; Dr. G. B. Mitchell, Mifflin; Dr. A. M. Neyman, Butler; Dr. Wm. Corson, Montgomery; Dr. I. N. Pierson, Adams; Dr. Wm. Heisen, Allegheny; Dr. P. L. Reichard, Lehigh; Dr. James Coblentz, Berks; Dr. James Eby, Perry; Dr. I. N. Snively, Franklin; Dr. Wm. Anderson, Indiana; Dr. C. A. Rahter, Dauphin; Dr. L. Turnbull, Philadelphia; Dr. R. Davis, Luzerne; Dr. J. S. Crawford, Lycoming; Dr. B. Leaman, Lancaster; Dr. John G. Stetler, Philadelphia; Dr. W. I. Ainey, Susquehanna; Dr. R. J. Levis, Philadelphia; Dr. Joseph McElroy, Washington; Dr. I. I. Morrow, Mercer; Dr. W. B. Ulrich, Delaware; Dr. W. M. Reber, Columbia; Dr. Traill Green, Northampton.

Place of meeting, Harrisburg. Time of meeting, second Wednesday, June, 1877.

Delegates were then appointed to the New Jersey Medical Society, New York State Society, Ohio State Medical Society, Delaware State Medical Society, West Virginia State Medical Society, Medical and Chirurgical Faculty of Maryland, Connecticut Medical Society, and International Medical Congress.

Any vacancies in the list of delegates to the Inter-

national Medical Congress to be filled by the President and Secretary.

On motion of Dr. Cohen, the report was adopted, with the exception of the delegation to the International Congress from Philadelphia.

Drs. D. S. Booth, of Illinois, D. E. Byrd, Arkansas, B. S. Woodworth, Indiana, were made members by invitation.

Dr. H. Corson offered a resolution to publish a report made some years ago on infanticide by Dr. A. Nebinger, and not then published.

The Committee of Publication stated that if this were published, it would establish a bad precedent, as it had already been published by another body. The resolution to publish it in the next volume of *Transactions* was agreed to.

Dr. Curwen, of the Committee on Insane Criminals, reported that they had failed to obtain the necessary legislation; also reported on the subject of the Southeastern Insane Asylum and the Insane Poor, and the memorial was ordered to be published with the *Transactions*. Dr. Curwen was requested to prepare a further statement, to be issued at once, and also published in the *Transactions*.

Dr. John L. Atlee, of Lancaster, offered resolution in regard to death of Dr. Edward Wallace. On motion of Dr. Deysdale, the salary of the Permanent Secretary was fixed at three hundred dollars. Reports were then presented from the Treasurer, and the Committee on Publication, the Committee on Anæsthetics, etc.

The Committee on Post-mortem Fees then recommended the repeal of all special legislation upon fees for autopsies. Also, that the fees established by county medical societies be the standard of charges for professional services; and that a committee be appointed, of one physician from each censorial district of this commonwealth, who shall procure the proper legislation (if possible) for the purpose.

After giving notice of amendments to the By-Laws and Constitution, the usual votes of thanks and a short address by Dr. Mowry, President-elect, the Society adjourned to meet at Harrisburg, June, 1877.

NEW YORK MEDICAL JOURNAL ASSOCIATION.

Stated Meeting, May 19th, 1876.

DRS. FOSTER AND STURGIS, VICE-PRESIDENTS, IN THE CHAIR.

THE TOPICAL USE OF THIN BIBULOUS PAPER IN AFFECTIONS OF THE SKIN AND MUCOUS MEMBRANES.

DR. G. H. FOX read a brief paper which contained a description of the material and an account of the uses to which he had put thin bibulous paper as suggested in the above title. Two varieties of the paper were described: the French, or that used by dentists for absorbing the saliva while operating about the mouth; and the Japanese. The former was made of vegetable fibre containing an admixture of wool; could be easily reduced to a pulp by moisture, and was capable of absorbing at least five times its weight of water. Its powers of absorption, perhaps, were no greater than those of good lint, but it absorbed far more rapidly. The Japanese paper, when moistened, did not reduce to a pulp, but could be rolled into cylinders and then would resist a large amount of traction. It could, therefore, be rolled and made to enter sinuses, the urethra, etc., if desirable, and was sufficiently strong to permit its easy removal. Dr. Fox regarded the paper, more especially the French variety, as a cheap and convenient substitute for lint, cotton, or absorbent powders, and that it could be easily used in a goodly number of cases. It might be used for cleaning bleeding surfaces, and would make an excellent substitute for sponges, which are so liable to convey the germs of disease from one person to another. In the treatment of the exuding forms of skin disease it was not regarded as of sufficient value to be worthy of recommendation. Its greatest value had been seen in the treatment of venereal disease, particularly genital sores. It had, however, served a very good purpose in the treatment of eczema of the breast occurring while nursing. The breast was simply covered with the paper, and frequently changed. When rolled into pellets of varying size, it formed a most admirable means for bringing fluid caustic substances in exact contact with the surface to be cauterized, and that surface only; for example, the application of nitric acid to the surface of a chancroid. When the pellet had been used it could be thrown away, and transmission of the disease by means of instruments, etc., was readily avoided. It was said that the best dressing for venereal sores was that which kept the discharge most constantly absorbed. Lint and cotton might do that, but they were difficult to remove, and a powder would form a crust that would be objectionable. The spongy paper readily absorbed the discharge, and, if frequently renewed, would keep the sore and surrounding parts clean without washing. As compared with lint, the paper was regarded as equal in every respect, and in many respects superior, because it absorbed a larger quantity and more readily, was easily removed, and cost only about one-fifth as much. The thin bibulous paper might be medicated, and specimens were exhibited medicated with fifty per cent. solution of carbolic acid; with persulphate and perchloride of iron, when it might be substituted for styptic cotton; with fifteen per cent. ethereal solution of iodoform, not specially recommended however; with thymol, calingula, etc., etc.

The paper was discussed by Drs. O'Sullivan, Post, Farnham, Robertson, Piffard, Bulkley, Taylor, Pooley, Sturgis, and others.

The dermatologists believed that the paper might be serviceable in the treatment of zoster, where a scab was desired. The oculists thought it might be used with advantage for cleansing the surface in suppurative forms of eye disease. The surgeons regarded it as a valuable means for controlling epistaxis and many of the milder hemorrhages.

It was commended as a substitute for and an accessory to the napkin ordinarily worn for the purpose of absorbing the menstrual discharge, and its non-irritant properties recommended it as a substitute for the handkerchief in the more or less constant attention demanded by an ordinary nasal catarrh.

A vote of thanks was tendered to Dr. Fox, and the Association adjourned.

M. VLEMINCKX. — Some details of the demise of Mr. Vleminckx make it probable that embolism was the cause of his death. He had suffered for a long time from some cardiac trouble, and it is thought that some acute disease of the heart, perhaps an ulcerative endocarditis, had set in in consequence of the disturbed nutrition consequent on the disease immediately preceding it. There were circumscribed foci in the lungs.

Correspondence.

MEDICAL CENTENNIAL AFFAIRS.

(From our Special Correspondent.)

GOVERMENTAL CONTRIBUTIONS — HOSPITAL CARS—THE U. S. HOSPITAL STEAMBOAT—AMPUTATING INSTRUMENTS OF THE REVOLUTION MICRO-PHOTOGRAPHS RARE BOOKS—LETTERS—AMBULANCES—A BLOODY PICTURE.

THE models of hospital cars are on the scale of an inch to the foot, and are made of hard wood or brass, with the rools removable to permit the inspection of the interior. Assistant Surgeon G. A. Otis, U.S.A., has recently described the various modes of transportation adopted in the army during the war, in a "Report on a Plan for transporting wounded Soldiers by Railway in Time of War," etc. Washington, S. G. O., 1875. The model exhibited represent: 1. the surgeon's car of a hospital train of the Army of the Cumberland. 2. The kitchen car of a hospital train of the same Army. 3. The form of car found most satisfactory for the transportation of sick and wounded in the same army. 4. A hospital car of the Army of the Potomac. 5. A freight car fitted up with litters for transporting sick and wounded.

The latter model is intended to represent the plan devised by Grund, a German master-machinist, and adjudged the most suitable for freight cars by the Prussian Commission of 1868. It consists "in supporting three ordinary field stretchers in the front, and three in the rear part of the freight car, twenty feet long, by means of transverse wooden bars, resting on semi-elliptical plate springs. The springs are spiked at one end to the flooring, to keep the bars stationary, while at the other end are rollers, to permit the yielding of the springs. The latter are surmounted by U pieces, or clips to receive the cross-bars. Four cross-beams and eight springs constitute the outfit requisite for the reception of six litters. Asst. Surg. Otis has recommended that, in any future war, the Quartermaster's Department of our army should be authorized to keep on hand a supply of these semi-elliptical springs. Trains going to the front with provisions, forage, or ammunition, should then each carry, suspended under the roof, a sufficient number of these springs, with the spikes required, to enable the car on its return, instead of going back empty, to carry comfortably, on beds improvised by means of the ordinary field stretchers, a number of sick or wounded corresponding to its size. He also suggests that these springs might be utilized in connection with field stretchers for the comfortable conveyance of the wounded in ordinary army wagons.

The model of the U. S. Hospital Steamboat D. A. January, recalls vivid reminiscences of her great usefulness during the war, 1861-5, upon the Western waters. She carried altogether 23,738 patients.

Among other articles on exhibition in this building are an amputating case used during the war of 1812; some amputating instruments employed by Dr. Benjamin Treadwell, on board of a man-of-war during the Revolution, &c. The latter forcibly illustrates the improvement in surgical appliances since that day, the amputating knives being sickle-shaped, and the spring lancet having a very antiquated and bulky appearance. Each window of the hospital is embellished with beautiful transparent micro-photographs, by Dr. Woodward, about sixty in all, while specimens of his ability and industry in this direction abound in numerous portfolios. The walls of the wards also contain similar illustrations, and Dr. Yarrow is also preparing a series of microscopic objects for examination and exhibition hereafter. We have no hesitation in expressing our belief that the U. S. Government, and notably our distinguished Surgeon-General, have done more for the encouragement of this cultivated taste in the Army Medical Staff than any other department or officials in any other country. The illustration of the apparent identity of shape of the blood-corpuscles of man and the dog, when magnified 4,350 diameters, is very suggestive, and particularly interesting to the medical profession.

Portfolios of photographs, of uniform size, of title or other pages, of rare books in the National Medical Library, at Washington, are also exhibited here. From a statement accompanying them, prepared by Dr. J. S. Billings, to whom the credit of collecting this great national treasury of medical literature is mainly due, we learn that the object is to show what has been accomplished in the attempt made by this department to form a collection of medical literature, which should meet the demands of the physicians of the United States. Many of the books are yellow with age, and all the yellow spots or stains appear in the photographs as dark or black spots. The photographs are arranged in three series: 1st. Those taken from early printed books, the so-called "Incunabula," and from other works, which are rare, at least in this country; 2d. Those relating to surgery, and especially to military surgery; and 3d. Rare books and pamphlets connected with American medical history. We shall hereafter have occasion to refer again to this interesting feature. There is a photograph of a specimen page of the oldest manuscript in the library, dated 1349, the "Lilium Medicum" of Bernard de Gordon; and of pages of the "Libellus de Egritudinibus infantum" of Paul Bagellardus, 1472, the first printed monograph on diseases of children: and of Benevenutus Grassus, Ferrara, 1475, the first printed monograph on diseases of the eye.

Of litters, ambulances, &c., there are numerous illustrations and specimens, both within the building and on its exterior, including Dr. McElderry's litter, allowing the patient to lie lengthwise on the horse, as employed in the Modoc campaign; the American field knapsack for the surgeon, much less roughly made than the Russian one which is alongside of it; the Tompkins' wheel litter; the new army medical pannier, which is very complete in its outfit, and superseding, by its greater lightness, the old form, consisting of two tin boxes; the ambulances devised by Hagner, Rucker, Ekin, and others, and the experimental ambulance, in accordance with the suggestions of a board assembled for that purpose; the convenient U. S. medicine wagon of J. Perot & Co.; that of Autenreith, etc. Drs. Otis and Huntington, U.S.A., have devised a wagon for the conveyance of U. S. medical stores, for rapidly marching field parties, which require only one horse. There is also in the second story of this model hospital an exhibition of the artificial limbs of various manufacturers, which are supplied through the Surgeon-General's office.

There is on exhibition on the first floor a large portrait of Prof. Gross in the act of performing an amputation in the presence of his class, painted by Mr. Thos. Eakins, of this city. The picture has much merit, and the likeness is excellent; but the coloring is not pleasant, and the subject is so repulsive, the Professor's unnecessarily bloody hand being the conspicuous feature of the scene, that we are not surprised that, for this latter cause alone, it was refused a place in the Art Gallery by the Committee of Selection, to find a more appropriate niche in the Army Hospital. R. J. D.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from May 28th to June 3d, 1876.

SMITH, J. R., Surgeon. To represent the Army Medical Department at the annual meeting of the American Medical Association at Philadelphia, on June 5th. S. O. 103, A. G. O, May 26th, 1876.

WOODWARD, J. J., Asst. Surgeon. To represent the Army Medical Department at the annual meeting of the American Medical Association at Philadelphia, on June 5th. S. O. 103, c. s., A. G. O.

BILLINGS, J. S., Asst. Surgeon. To represent the Army Medical Department at the annual meeting of the American Medical Association at Philadelphia, on June 5th. S. O. 103, c. s., A. G. O.

WILLIAMS, J. W., Asst. Surgeon. In addition to his duties as Chief Medical Officer, to take charge of the Battery and Captain Baker's company, 6th Infantry. S. F. O., Headquarters, Department of Dakota (in the field), May 14th, 1876.

HUBBARD, V. B., Asst. Surgeon. To accompany battalions of 4th Artillery to and from Sitka, Alaska, and upon completion of this duty, to rejoin his station—Alcatraz Island, Cal. S. O. 66, Division of the Pacific, May 23d, 1876.

BROOKE, JNO., Asst. Surgeon. Assigned to duty at Columbia, S. C. S. O. 73, c. s., Department of the South.

KINSMAN, J. H., Asst. Surgeon. Granted leave of absence for one month. S. O. 70, Department of Dakota, May 24th, 1876.

BAILY, J. C., Surgeon. Assigned to duty as Post Surgeon at Newport Barracks, Ky. S. O. 73, Department of the South, May 29th, 1876.

TAYLOR, M. K., Asst. Surgeon. In addition to his duties as Post Surgeon, to perform those of attending Surgeon at these Headquarters. S. O. 93, Department of Texas, May 24th, 1876.

WHITE, R. H., Asst. Surgeon. Assigned to duty as Post Surgeon at Ringgold Barracks, Texas. S. O. 93, c. s., Department of Texas.

ELBREY, F. W., Asst. Surgeon. Assigned to duty as Post Surgeon at McPherson Barracks, Atlanta, Ga. S. O. 73, c. s., Department of the South.

JACKSON, D., Asst. Surgeon. Granted leave of absence for four months, with permission to go beyond sea. S. O. 103, A. G. O., May 26th, 1876.

FINLEY J. A., Asst. Surgeon. Leave of absence extended one month. S. O. 51, Military Division of the Missouri, May 31st, 1876.

REED W., Asst. Surgeon. Assigned to duty at Camp Lowell, O. T. S. O. 59, Department of Arizona, May 9th, 1876.

SPENCER W. G., Asst. Surgeon. Assigned to duty at Raleigh, N. C. S. O. 73, c. s., Department of the South.

Medical Items and News.

TRAUBE'S SUCCESSOR.—Among the candidates who are named to succeed Traube at the Charité in Berlin, are Professor Friedreich of Heidelberg, and Leyden of Strasburg. Professor Schiff, of Florence, is to be professor of Physiology at the Geneva School, in place of Brown-Séquard, who has declined. Vaucher is to have the chair of Obstetrics; Colnstein, of Gynecology; D'Espine of Internal Medicine; Prévost, of Materia Medica; and Gosse, of Medical Jurisprudence.

DECREES OF THE COURT OF APPEALS.—The French Court of Appeals delivered the following decision on March 31st, 1874: "A physician is guilty of swindling, who, by means of lying advertisements, vaunts his method of treating diseases, and publishes certificates which he has obtained fraudulently, and which certify falsely to cures of diseases declared incurable by other physicians."

Again, by a decision of the 25th of last March, an apothecary who, without the prescription of a physician, where the case was not of urgent necessity, sells a medicinal preparation, composed of several different ingredients, renders himself liable to prosecution for the illegal practice of medicine.—*Bordeaux Médical.*

MANHATTAN EYE AND EAR HOSPITAL.—There has been added a new department to the services of the Manhattan Eye and Ear Hospital, namely, that for nervous diseases. Prof. E. C. Seguin has been elected to fill it. This important step in the development of the hospital will tend to bring the specialties of the eye, ear, and throat, and diseases of the nervous system, into closer relations in the clinics of the institution, and insure a careful scrutiny of all cases and the greatest scientific accuracy in the investigation of those which seem to be marked by some peculiar neurosis.

CONNECTICUT MEDICAL SOCIETY.—At the annual meeting of this medical society, held in New Haven, May 24th and 25th, Dr. A. W. Barrows, of Hartford, was elected President; Dr. R. Hubbard, of Bridgeport, Vice-President; Dr. F. D. Edgerton, of Middletown, Treasurer; Dr. C. W. Chamberlain, of Hartford, Secretary.

ROCKLAND CO. MEDICAL SOCIETY.—At the annual meeting of the Medical Society of Rockland County, N. Y., held May 30th, 1876, the following gentlemen were elected officers for the ensuing year; viz.—President, Dr. J. J. Stephens, Tappantown; Vice-President, Dr. B. H. House, Rockland Lake; Secretary, Dr. William Govan, Stony Point; Treasurer and Librarian, Dr. Jacob Wigton, Spring Valley. *Censors*, Drs. J. O. Polhamus, J. Wigton, and J. Waring; Delegate to the State Medical Society, J. O. Polhamus.

UNIVERSITY OF MICHIGAN, AND THE RECOGNITION OF LECTURE TICKETS.—We are asked to make the announcement that official communications have been received during the present week by the Faculty of the old school of the University of Michigan, from Bellevue Hospital Medical College, and the College of Physicians and Surgeons, of N. Y. and the Long Island Hospital College of Brooklyn, announcing that they will accept the tickets of the University of Michigan, and recognize its graduates as heretofore.

MEDICO-LEGAL SOCIETY.—This society held its last meeting of the season on the evening of June 7th.

AIR-TIGHT VACCINE CASE.—The Case Record Company of Cincinnati have manufactured what appears to be a very useful vaccine case. It is so constructed that it is capable of excluding light, heat, and air. It consists of a tube of hard rubber open at each end and provided with lids which screw down closely, and by means of india-rubber packing render the tube absolutely air-tight. Near the lower end of the tube is a perforated diaphragm dividing the tube in two compartments, in one of which (the lower) is a piece of freshly burnt lime in cotton. The upper compartment is for the vaccine crusts, quills or ivory points. It is claimed that by this means crusts and quills can be kept for months in a perfect state of preservation, and be sent thousands of miles by land or sea.

ENGLISH DEBATE ON SYPHILIS.—We shall continue our review of this subject in our next issue.

Reports of Societies.

AMERICAN MEDICAL ASSOCIATION.

TWENTY-SEVENTH ANNUAL MEETING.

PHILADELPHIA, June 6, 7, 8, 1875.

TUESDAY, JUNE 6—FIRST DAY.

THE Association met at Horticultural Hall, Philadelphia, Tuesday, June 7, and was called to order at eleven A.M. by Dr. Wm. Pepper, Chairman of the Committee of Arrangements. A prayer was then offered by the Rev. Dr. Beadle, after which Dr. W. K. Bowling, of Kentucky, introduced the President-elect, Dr. J. Marion Sims, of New York. The latter was supported by the following officers of the Association: Vice-Presidents, Drs. Samuel Lilly, of New Jersey; Ninian Pinckney, U. S. N., and S. D. Scelye, of Alabama; Dr. W. B. Atkinson, Secretary, and Dr. R. J. Dunglison, Assistant Secretary.

DR. PEPPER, on behalf of the Committee of Arrangements, delivered an address of welcome to the delegates, in which he referred to the attractive medical features of Philadelphia, its sanitary resources, its medical schools and organizations, concluding with a resolution inviting the following gentlemen to seats upon the platform: Surgeon-General William Roth, 12th Corps (Royal Saxon) German Army, and staff, viz., Assistant Surgeon Hans Heymann, 12th Corps (Royal Saxon) German Army, and Dr. Max Brille, Dresden, Germany. Members by invitation: Dr. Wywoodzoff, of St. Petersburg, of the Russian Commission; Le Docteur Gaffray, representative of the Paris Press to the Exposition; and Surgeon-General J. K. Barnes, U. S Army.

The reading of the roll of registered delegates was dispensed with, after some discussion, when the Secretary read a letter from Dr. William O. Baldwin, late President of the Association, regretting his inability to be present.

ADDRESS OF THE PRESIDENT—HISTORICAL REMINISCENCES—MEDICAL EDUCATION—THE CODE OF ETHICS AND MEDICAL PATENTS—STATE MEDICINE—THE PREVENTION OF PROSTITUTION.

The President, DR. J. MARION SIMS, of New York, then read his inaugural address.

After congratulating the delegates on the privilege of meeting in Philadelphia, in the Centennial year, and joining in the Centennial celebrations, the speaker said that they were standing on hallowed ground,—hallowed because the birth-place of a nation. A century was a brief period in the history of nations, but in that time we had increased from 3,000,000 to more than 40,000 000 of people, and had made our mark in science and letters. Although the organization of the Association was conceived in New York, its actual birth-place was in Philadelphia, twenty nine years ago, its first scientific meeting being in Baltimore in 1848. Formed mainly for the purpose of improving the medical educational interests of America, it had exerted some influence in the direction intended. Although it had failed to meet the ardent expectations of its projectors, it had nevertheless vindicated its claims to the rank of the representative medical body of the country. It was not, however, due to any want of disposition to effect reforms in medical education that not more was effected. In fact it had engaged the attention of the Association at every meeting since its formation, and volumes had been written on the subject. Dr. William O. Baldwin, of Alabama, President of the Association in 1869, in his inaugural address had ably set forth the defects of the present method of medical education, and had proposed as a remedy the establishment of a great national university, under Government auspices, at the capital. If the large sum necessary for such a university could be obtained from the Government, its graduates would doubtless rank with those of the best foreign universities. He had felt greatly interested in Dr. Baldwin's scheme, and had been anxious to see it carried out. To this end he had consulted some of the wisest and ablest educationists in the country, and had also taken counsel with some of the great political leaders of the day; but he regretted to say that he had found so little sympathy with the project, that he had been unwillingly forced to let the subject rest in abeyance for the time being. The Harvard method, with a salaried Faculty wholly independent of fees from students, was in his opinion the only plan by which a medical degree of any real value could be gained. Five or six hundred thousand dollars given to the Medical Department of the University of New York, or to either of the schools of New York or Philadelphia, properly invested, would yield an annual income sufficient to endow the professorships in said school. This would make the professors independent, and they would not be compelled to graduate young men merely for the sake of the numbers graduated, irrespective of qualification. The University of Virginia was, perhaps, the best training-school in the country, but unfortunately its want of hospital advantages crippled its practical teaching.

In speaking of the practical application of the provisions of the Code of Ethics, he doubted if the latter were wholly up to the present requirements. For instance, he questioned the wisdom of preventing medical patents. He asked why any man should be debarred from taking out a patent for a useful invention, merely because he happened to be a physician. Did the profession at large, or did the public, derive any benefit by the robbery of the inventor? None whatever. He was simply compelled to give his invention, his time and labor, to enrich the instrument-maker.

Again, the Code of Ethics was violated every day, either wilfully or ignorantly, not only by the rank and file, but by men high in the profession; men who were considered leaders, advanced thinkers and workers. How many of those present prescribed chlorodyne, McMunn's elixir of opium, Henry's calcined magnesia, and the Tolu anodyne? Yet they were secret remedies. The prescription of all such remedies was a flagrant violation of their Code of Ethics. But they seemed to condone the act, because usage and interest justified it.

The subject of State medicine was next touched upon as one of the greatest importance, and he remarked that the address of Dr. Bowditch, foreshadowing the practicability of inaugurating a movement of the establishment of a National Health Bureau, commended itself to the attention of the members so far as the initiatory formation of State Boards of health was concerned.

In conclusion, he alluded to the vexed question of legislation against syphilis and prostitution, condemning the legalization of the latter, and advising all the matters connected with the spread of the disease to be handed over to the Health Boards.

MISCELLANEOUS BUSINESS.

After a vote of thanks had been tendered for the

address, Dr. Pepper then announced that the Medical Building, directly behind the Judges' Hall, in the Landsdowne Ravine, would be used as a place of rendezvous for physicians visiting the Centennial.

The times and places of meeting of the sections were next announced.

Dr. Toner, of Washington, moved that ten o'clock on Wednesday be set apart for the reading of the Address on Surgery.

Dr. Toner called upon the Secretary to read the list of the reports to be presented, which was done. A motion was then made to adjourn until three o'clock, and at the same time an effort was made to change the place of meeting to some other hall, but without success. The meeting then adjourned to nine o'clock on Wednesday.

EVENING ENTERTAINMENT.

During the evening the members accepted the invitation of the Committee of Arrangements to a grand promenade concert and supper at Horticultural Hall. The attendance was large and the occasion enjoyable to all.

WEDNESDAY, JUNE 7—SECOND DAY.

COMMITTEE ON NOMINATIONS.

The meeting was called to order by the president pursuant to previous adjournment.

The following Committee on Nominations was appointed:

Alabama, L. B. Sulze; Arkansas, George T. Hood; California, W. Baker; Connecticut, A. Woodward; Delaware, W. Marshall; District of Columbia, J. Elliott; Florida, G. W. Betton; Georgia, J. P. Logan; Indiana, L. Humphrey; Illinois, T. D. Washburne; Iowa, W. Watson; Kentucky, H. M. Skillman; Kansas, C. V. Mattson; Michigan, A. S. Heaton; Massachusetts, A. B. Hall; Minnesota, E. C. Cross; Maryland, Thomas F. Latimer; Maine, A. B. Snow; Missouri, John T. Hodgen; Mississippi, William Campton; New Hampshire, J. L. Swett; New York, N. C. Husted; New Jersey, S. Lilly; North Carolina, E. Grissom; Ohio, W. J. Scott; Pennsylvania, Traill Green; Rhode Island, L. C. Butler; South Carolina, James McIntosh; Tennessee, John H. Callender; Texas, E. Darnell; Vermont, W. D. Holton; Virginia, J. S. Wellford; West Virginia, J. C. Hupp; Wisconsin, H. P. Strong; U. S. Army, J. R. Smith; U. S. Navy, A. L. Gihon.

The Judicial Council reported that they had decided that the delegates from the Arkansas State Medical Society were entitled to recognition.

NATURAL PURIFIERS—WATER SUPPLY AND SEWERAGE.

Dr. R. C. Kedzie, of Lansing, Mich., read a paper with the above title. He contended that the conditions of water and air were the main if not the only ones upon which the discussion of his subject rested, but the purifier *par excellence* was oxygen.

In conclusion the gentleman offered the following resolutions, which were adopted:

Resolved, That it is the first duty of States and municipalities—first in importance, and first in the order of time—to make a sanitary survey of the water supply to preserve it against all unnecessary and avoidable contamination.

Resolved, That no municipality should introduce a water system without at the same time providing a corresponding and extensive sewer system.

Doctors Wilhelm Hiorth and H. G. Holst, Medical Directors, Christiania, Sweden, were made members by invitation.

CENTENNIAL SURGERY.

Dr. A. Garcelon, of Maine, read an address on the Progress of Surgery during the past century. He remarked that in 1776 this country was so sparsely settled, and only two cities having a population of over 20,000 inhabitants, that but few men of high scientific attainments could find employment for their skill. Under such circumstances ignorance and empiricism prevailed. A half century later we had made but little progress. The establishment of medical schools and hospitals, and the publication of medical journals, followed the commencement of the present century, and the war of 1812 imparted to them an additional stimulus. Since 1800 the number of these had increased with great rapidity, and the schools now numbered not less than one hundred, besides a large number of preparatory schools. Although many of the graduates of these institutions ranked as the peers of those of any age or country, and as practical operative surgeons they have no known superiors, it was quite evident that the present system of college instruction, if continued, would effectually undermine such a reputation. The lax laws in reference to graduation were next alluded to, and a greater restriction of graduating privileges was earnestly urged.

UNIFORMITY OF MEDICAL OBSERVATION AND NATIONAL MEDICAL CONGRESS.

Dr. Edward Seguin, N. Y., made the following report:

For several years, the American Medical Association has given its support to a measure of great interest for those who have at heart the advance of physic, namely, the establishment of uniform means of observation, and of medical records, for the physicians of all countries. This action of the American Medical Association has been expressed by the adoption of successive resolutions, and by the sending of delegates charged with the mission of advocating this reform:—in 1873, to the British Medical Association, meeting in London; and to the French Association for the Advancement of the Sciences, meeting at Lyons. In 1874, to the British Medical Association, meeting at Norwich; and to the French Association for the Advancement of Sciences, meeting at Lille. In 1875, to the International Medical Congress, meeting at Bruxelles. In 1876 (next September), the same congress will meet in this very place; and now the American Medical Association is called to decide what position it will assume in this matter.

Will it recede from its former position, and leave the task to second-hand promoters, or will it continue its initiative before the International Council? This is not only a question of pride for the Association; it is also one of justice due to the American physicians at large. If the constitution and by-laws of this Association prescribe an annual transfer of its meetings from one part to another of this vast country, it is to give us opportunities to study and express the wants of the whole profession. Of these wants, none has been found more deeply felt than the one of partaking, as givers and receivers, in the discoveries of our art. But this want is not ours alone, it is universal; and the American Medical Association will deserve the thanks of all for having planned, and carried into execution, the most important instrument of internationalization of the medical progress.

Therefore the Association resolves to charge its delegates of former years to continue to advocate the uniformity of means of observation before the various

medical societies, and particularly at the next International Medical Congress, and report next year what success they will have met.

Doctors Seguin and Bowditch were appointed additional delegates to the International Congress.

REPORTS OF TREASURER, PUBLICATION AND LIBRARY COMMITTEES.

The report of the Treasurer showed that there was an unexpended balance of $4,577.07 in his hand to date.

The report of the Committee of Publication stated that of the volume of the *Transactions* for 1875, nine hundred and fifty copies were printed, at an aggregate expense of $2,000. Of these, 883 copies have been distributed to members, 28 to medical journals and societies, leaving 39 on hand.

The report of the Librarian stated that during the past year there had been added to the library 124 distinct titles, exclusive of yearly volumes of transactions of societies, reports of hospitals and boards of health, and volumes of medical journals, where these have been previously catalogued as distinct titles. This addition makes the library consist at present of 630 distinct titles, which comprehend 1,514 volumes, including pamphlets.

The report of DR. C. C. HOWARD, delegate to the Brussels International Medical Congress, held in September last, was presented, and referred to the Committee on Publication.

A sketch, prepared by PROF. HAILES, of the life of Dr. Armsby, of Albany, N. Y., was, on motion, referred to the Committee on Publication.

The meeting then adjourned until 9.30 A.M. on Thursday.

The afternoon was occupied in the meeting of the different sections.

In the evening a lecture was delivered by PROF. GEORGE F. BARKER, M.D., of the University of Pennsylvania, on the "World of the Seen and the Unseen." After explaining some of the phenomena connected with optical delusions, and showing how scientific investigation was passing into a field where the senses were absolutely insufficient to search, the lecturer gave a number of illustrations, showing the methods of investigation into matters beyond the reach of the senses, as sound and light, many of which were very beautiful and elicited great applause.

THURSDAY, JUNE 8—THIRD DAY.

Horticultural Hall having proved inadequate to the requirements of the meeting, Kiralfy's Alhambra Palace was selected for this morning's session. The meeting for this day was accordingly called at that place, and commenced, pursuant to previous adjournment, at 9.30 A.M., President Dr. J. Marion Sims in the Chair.

REGISTRATION AND MEMBERSHIP.

On motion, the resolution of the day before, that all persons whose names are at present on the roll shall be voted members, was reconsidered, and it was agreed, after some discussion, that the roll of members, amounting to some 730 names, be called. In accordance with this desire the Secretary began calling the roll, and continued to do so until ten o'clock, when the hour arrived for the reading of the

ADDRESS ON OBSTETRICS, by DR. S. C. BUSEY, of Washington, D. C.

On the conclusion of the reading, DR. J. L. ATLEE moved that the address be referred to the Committee on Publication, for publication, and discussed at the next meeting of the section on Obstetrics. Adopted.

The effort was then again made to do away with the reading of the roll, but unsuccessfully. The motion occasioned considerable discussion.

MICHIGAN STATE SOCIETY AND DELEGATESHIP.

On the reading of the roll, at the name of a delegate from the State Society of Michigan, the delegate was objected to, as coming from a society against which charges were pending. At this juncture the report of the Judicial Council, signed by Dr. Benham, Chairman, recommending that the delegates from Michigan State Society be received, was presented. The report was applauded, and the reading of the roll was continued.

MEMBERS IN ABSENTIO.

At the name of Dr. Thomas J. Griffiths, of Louisville, an objection was made that he was not or had not been present, and the Secretary was requested to strike his name from the roll if the objection should be found, on inquiry, to be well founded.

FEMALE REPRESENTATION.

On the reading of the name of Sarah Hackett Stevens, representing the Illinois State Society, DR. BRODIE, of Detroit, moved that that and all such names be referred to the Judicial Council. A motion that this resolution be laid upon the table was carried by a large vote, amid considerable applause.

The President asked if the vote was intended to recognize her right to a seat, when loud cries of "Yes," and cheers, emphatically answered the question.

DR. TONER, of Washington, moved that the roll as read be confirmed, with the exception of the objections taken.

THE QUESTION OF PATENTS IN MEDICINE.

A resolution providing that it was not derogatory in any physician to take out a patent for a surgical instrument of any kind, was referred to the Judicial Council.

THE MCDOWELL MEMORIAL FUND.

DR. KELLER, of Kentucky, on behalf of the trustees of the fund for amonument to the late Dr. McDowell, of Kentucky, reported a recommendation for an increase of one dollar each year in membership dues, the amount thus raised to go to said fund.

DR. TONER stated that the resolution so recommending would have to lay over one year, under the rules. He hoped, however, that the rules would be waived for this purpose by unanimous consent.

Objection was raised, and a motion to lay the resolution on the table was agreed to.

DR. TONER moved that $1,000 be appropriated out of the funds of the Association for the McDowell fund.

DR. HOWARD moved the point of order that it was a rule of the Association that no new business should be transacted except on the first and fourth days of the session of the Association, and hoped the rules would not be departed from. The Chair decided the order well taken, and the motion of Dr. Toner was declared out of order.

DR. SIMS said he was as anxious as any one to secure the money asked for, but after conversation with gentlemen around him he was satisfied the subject could not be discussed to-day. The Association would have to defer action until to-morrow.

DR. HENRY A. MARTIN, of Boston, moved that a committee be appointed by the Chairman to take into consideration the subject of bovine vaccination as compared with the usual arm to arm practice, to report

at the next annual meeting. The motion was adopted, after which the Association adjourned at 9.30 A.M. on Friday.

AFTERNOON AND EVENING.

The sessions held their usual meeting in the afternoon and completed the business before them.

The evening was spent on the part of the members in responding to invitations to the receptions of the following Philadelphian physicians and surgeons: Drs. D. Hayes Agnew, J. Solis Cohen, Louis A. Duhring, H. Lenox Hodge, John H. Packard, William H. Pancoast, William Pepper, and Ellwood Wilson.

FRIDAY, JUNE 9—FOURTH DAY.

The closing session of the Association was held in Horticultural Hall, and was called to order by the President at 9.30 A.M.

A charge against the State Society of Illinois was referred to the Judicial Council.

THE GRADUATION OF "IRREGULAR" PERSONS.

DR. TONER, of Washington, offered the following, which was unanimously adopted:

Resolved, That members of the medical profession who in any way aid or abet the graduation of medical students in irregular or exclusive systems of medicine, are deemed thereby to violate the spirit of the ethics of the American Medical Association.

STATE BOARDS OF HEALTH IN EXISTENCE.

DR. W. B. ATKINSON, the Secretary, presented a report which stated that in obedience to the resolution adopted at the session of 1875, he reports that in reply to his inquiries he is informed that Boards of Health exist in Alabama, California, Georgia, Massachusetts, Michigan, Minnesota, Virginia, and Wisconsin. He had written to the Governors of Delaware, Indiana, Iowa, Nebraska, New Jersey, New York, South Carolina, Texas, and Vermont with almost negative results.

CATALOGUE OF NATIONAL LIBRARY.

DR. H. C. WOOD, of Philadelphia, offered the following, which was adopted:

Resolved, That a committee of three be appointed by the Chair to obtain from Congress an appropriation for the publication of the subject catalogue of the National Library, and that the State Societies are requested to take such action as may be deemed fit to further said object.

OFFICERS ELECTED FOR 1877.

The Nominating Committee next presented the following report through their Chairman, which was duly adopted:

President—Dr. Henry J. Bowditch, of Massachusetts.

Vice Presidents—Dr. N. J. Pittman, of North Carolina; Dr. Franklin Staples, of Minnesota; Dr. Joseph R. Smith, of U. S. Army; Dr. Samuel C. Busey, of Washington, D. C.

Treasurer—Dr. Casper Wister, of Pennsylvania.

Librarian—Dr. William Lee, of District of Columbia.

Committee on Library—Dr. Johnson Eliot, of District of Columbia.

Assistant Secretary—Dr. J. H. Hollister, of Illinois.

Committee of Arrangements—Drs. N. S. Davis, J. W. Freer, H. A. Johnson, T. D. Fitch, H. W. Jones, Joseph P. Ross, Leslie Curtis.

Committee of Publication—Dr. W. B. Atkinson, chairman; Dr. T. M. Drysdall, Albert Fricke, Samuel D. Gross, Casper Wistar, Richard J. Dunglison, all of Pennsylvania; and Dr. Williams, of District of Columbia.

Next place of meeting—Chicago, Ill.

Time of meeting—First Tuesday in June, 1877.

Judicial Council—Drs. N. S. Davis, of Illinois; E. L. Howard, of Maryland; W. O. Baldwin, of Alabama; H. W. Dean, of New York; A. N. Talley, of South Carolina; J. P. Logan, of Georgia; and D. W. Stormont, of Kansas, in place of the seven whose terms expire at this meeting. The rest of the present Council continue.

Committee on Prize Essays—Dr. N. S. Davis, Illinois, chairman; Edmund Andrews, E. Ingalls, Moses Gunn, E. P. Cook, all of Illinois.

Special Committee on Influence of Climate in Pulmonary Diseases in Florida—Dr. E. T. Sabal, continued.

DELEGATES TO INTERNATIONAL MEDICAL CONGRESS.

Delegates to the International Medical Congress to be held September 4th, 1876, at Philadelphia: Drs. H. I. Bowditch, Massachusetts; E. Seguin, New York; Thomas L. Maddon, Iowa; J. S. Welford, Virginia; A. Dunlap, Ohio; John T. Hedgen, Mo.; Joseph Carson, Pa.; John C. Dalton, N. Y.; W. O. Baldwin, Ala.; D. W. Yandell, Ky.; N. S. Davis, Ill.; Austin Flint, Sr., N. Y.; T. G. Richardson, La.; W. F. Westmoreland, Ga.; A. M. Pollock, Pa.; Frank Hastings Hamilton, N. Y.; G. M. Bemiss, La.; L. A. Dugas, Ga.; Francis Bacon, Conn.; Hunter McGuire, Va.; A. G. Shortleff, Cal.; E. M. Moore, N. Y.; O. W. Holmes, Mass.; G. A. Otis, U. S. Army; F. E. Gunnell, U. S. Navy; E. C. Harwood, of New York.

SALARY OF THE PERMANENT SECRETARY.

On the motion of DR. J. L. ATLEE, of Lancaster, the salary of Dr. W. B. Atkinson, the permanent secretary, was made $1,000 for the past year.

THE NECESSITY FOR STATE BOARDS OF HEALTH.

DR. BELL, of Iowa, offered the following, which was adopted:

Resolved, That there be appointed a committee of three persons, members of this Association, in each of those States where there has been no action taken for the establishment of Boards of Health, to urge upon those States the necessity of the establishment of such Boards.

A LIST OF REPUTABLE MEDICAL COLLEGES ASKED FOR.

A communication was read from the Centennial Commissioners from Victoria, asking information as to the list of medical colleges in good standing in this country. A motion was made to refer it to the Judicial Council.

DR. BUSEY said the Judicial Council did not have the right to determine the standing of any college.

DR. FROTHINGHAM, of Michigan, said the quarrels about the colleges were a disgrace to the profession.

On motion of DR. TONER, the whole matter was laid on the table.

CLOSING ADDRESSES.

The newly-elected President, Dr. H. I. Bowditch, of Massachusetts, was then conducted to the chair, and DR. SIMS, the retiring President, delivered his farewell address. He said the work transacted during the past three days would exhibit to science a record of progress greater than ever before. At this meeting many familiar faces had been missed. Francis Gurney Smith, who had served them long and faithfully, was abroad to recuperate his shattered health.

The absence of so many of our Southern brethren was not due to any lack of interest in the proceedings. He thanked God that the day of strife had been passed, and passed forever. Where there had been bitterness and hate, now there was kindness and affection. What higher proof could there be of this than the election of a man educated at the South? At this time Massachusetts and South Carolina can join hands. (Dr. Sims then clasped the hand of the newly-elected President, Dr. Bowditch, the act being received with shouts of applause.)

Dr. Bowditch then addressed the Association, and said the place had sought him and not he the place. He deemed it a special honor to occupy the position in this Centennial year. In conclusion, he returned his sincere thanks.

Dr. GRISSOM, of North Carolina, thanked Dr. Sims for his remarks.

THE UNITED STATES PHARMACOPŒIA.

DR. E. R. SQUIBB, of Brooklyn, N. Y., remarked upon the practicability of revising the Pharmacopœia, after which he offered the following, which were adopted:

Whereas, The usual time for a decennial revision of the United States Pharmacopœia is drawing near; and

Whereas, The plan of revision and publication in force since 1820 may not now be the best that could be devised; therefore, be it

Resolved, That the American Medical Association take the whole subject of the National Pharmacopœia into consideration for a revision of its management, and for the present time, with especial reference to the following questions:

First. Whether the present plan of decennial revision and publication be practically sufficient for the needs of the Materia Medica and Pharmacy of the present time, and, if not sufficient, whether a plan could be devised which might offer probable advantages enough to justify an attempt to disturb the present one.

Second. Whether this Association be the proper custodian in this country of the interests involved in the National Pharmacopœia; and if it is the proper source of the National Codex, whom can it invite to co-operate with it in the work?

Third. If it be a work for this Association, in what way can its details be wisely undertaken with any prospect of material improvement upon the present plan?

Resolved, That in order to facilitate mature and general deliberation upon so important a subject, the final discussion of these resolutions be laid over at least one year; and that the matter be recommended to the President of the Association for consideration in his annual address for the meeting of 1877.

On motion, the thanks of the Association were returned to the Messrs. Kiralfy, proprietors of the Alhambra Theatre, for the loan of their beautiful building on Thursday.

The Association then adjourned *sine die*.

NEW YORK COUNTY MEDICAL SOCIETY.

Stated Meeting, May 22, 1876.

DR. H. B. SANDS, PRESIDENT, IN THE CHAIR.

ON A LOST ART IN SURGERY.

DR. A. B. CROSBY, in an interesting paper upon the above subject, was inclined to the opinion that man was a dirty animal, and if by means of water he improved upon his condition in that respect, he deserved commendation therefor. Man might be in respectable health in spite of filth, but *cleanliness* was the *sine qua non* of the successful surgeon, for filth in a wound meant poison, and poison meant death. The doctor believed that cleanliness in its highest sense was almost unknown in the metropolitan hospitals of the world, hence a *lost art in surgery*, and to indicate how it was to be restored was the object of the paper.

Dr. Crosby gave a brief account of the first pavilion hospital built during the late war, and erected under his supervision in the summer of 1861. He received for its first occupants the wounded from the battle of Ball's Bluff. The doctor, at the time of its erection, was entirely ignorant of the action that had been taken by the Sanitary Commission, and the building was occupied before their action was announced. In that hospital the sum of the treatment was absolute cleanliness; cleanliness with reference to the floors of the wards, the body and bed linen of the patients, and the bodies of the patients were also sponged with warm water very frequently. All the wounds were treated openly; all offensive wounds were treated with antiseptics; and no wound was brought together until the surface was covered with fresh healthy granulations. Absolute cleanliness, nutritious food, and pure air formed the tripod upon which the hospital rested, and to those the excellent results were mainly attributed. "Fortunately," said the doctor, "our requisitions for drugs remained unfilled," and the medical supplies consisted chiefly of opium, whiskey, and a few pounds of copperas, which was obtained at a country store, and was pulverized and administered mixed with molasses. Of all cases treated, only ten per cent terminated fatally.

Dr. Crosby next referred to the terrible mortality at one time seen in the wards of one of the divisions in Bellevue Hospital; gave an account of the disinfecting process* instituted and executed by Prof. Doremus; and cited the results obtained since the disinfection, the wards being occupied by surgical cases under the care of Dr. James R. Wood. Since the disinfection no cases of erysipelas, gangrene, ulcers, or burns had been permitted to enter the wards; and if, by mistake, a case of either of those affections had gained entrance, or had developed in the wards it was at once removed, and the bed thoroughly cleansed before being occupied by another patient. Sponges were discarded; each patient had his own bottles and brushes, and brushes were used but once; instruments and the hands of the attendants were washed in carbolized water before passing from one patient to another, etc., etc. In short, absolute cleanliness and continued disinfection had prevailed; and the result had been that pyæmia had not been seen, only one or two cases of erysipelas had occurred, and those had been in cancerous cases; and Dr. Crosby had treated successfully, in the same wards, compound comminuted fractures, with extensive laceration of the soft parts.

"Sepsis," said the doctor, "has not gained a habitat in these wards since disinfection and cleanliness have been absolutely enforced."

A similar train of facts was brought forward with reference to the Long Island College Hospital. In that institution clean hands, clean wounds, clean

* A detailed account of the process of disinfection, carried out by Prof. Doremus, may be found under the head of remarks made by Dr. Lordyce Barker, in the discussion of Dr. W. T. Lusk's paper "On the Genesis of an Epidemic of Puerperal Fever," and published in the number of the MEDICAL RECORD for October 23, 1875. An abstract of Dr. Lusk's paper can be found in the same number of the RECORD.

sponges and clean everything had driven the enemy out; and the chlorinated liquor of soda had become a standing monument over the grave of the schizomycete.

The doctor maintained that sepsis in a hospital was a crime, that cleanliness would prevent its extension, and disinfection would drive it from its stronghold; and that the facts recited plead with mute eloquence for the restoration of the lost art. Every possible connection from one wound to another, however, must be cut off, or the original evil would crop out.

Perhaps the most important feature of the paper was its bearing upon the question whether metropolitan hospitals which have been occupied for many years could be cleansed and rendered as safe as new structures? The pavilion plan has received general recognition; and with such recognition has come, at least, a tacit condemnation, for hospital purposes, of those structures which consist of several series of rooms, one above the other, and enclosed by brick or stone walls. Now, if such buildings, which have become infected, can be disinfected—which have been poisoned, can have that poison dislodged—an immense amount of money and hard labor could be saved. Dr. Crosby was of the opinion that all such poisoned wards might be entirely and perfectly disinfected, if recourse was had to proper measures.

The paper was discussed by Drs. Ludlum, Janeway, Sell, and Sands. At the close of the discussion, Dr. Janeway exhibited a leucocythæmic spleen, having measurements next to the largest upon his records. It was removed from the body of the man (Case I.) whose history was given in the paper from Dr. Janeway, lately published in the RECORD, measured fourteen inches longitudinally, by nine inches transversely, and was four inches thick and weighed seven and one-half pounds. The liver of the same man weighed seven pounds and contained spots of leukæmic formations. The left kidney was atrophied from pressure, and had quite a sulcus made by the spleen. The sp. gr. of the blood was 1036. Farther analysis had not been completed.

NEW YORK MEDICAL JOURNAL ASSOCIATION.

Stated Meeting, May 26, 1876.

DR. E. G. LORING, PRESIDENT, IN THE CHAIR.

ON SOME POINTS IN THE ETIOLOGY OF HEREDITARY SYPHILIS.

DR. F. R. STURGIS, in a concise and brief paper upon the above subject, presented a criticism upon the opinion still entertained by a large part of the medical profession, that the ovum in utero may become infected with syphilis through the semen, without the transmission of syphilis to the mother, either by the father or by the fœtus.

Dr. Sturgis was of the opinion that those who still adhered to this doctrine entered the discussion in the face of three disadvantages.

1. They were obliged to prove positively the presence of syphilis in the father and child.

2. The non-existence of the disease in the mother, past, present, and future.

3. To explain certain anomalous cases and conditions which did not perplex those who held to contrary opinions, for they had only to prove that the mother and child were healthy.

In criticising the opinion stated, the doctor asked the question, "Why is it unlikely that syphilis should exempt the mother and attack only the ovum?"

Infection by the natural excretions of the body, viz.: the sweat, saliva, tears, milk, etc., had been exploded as impossible, and yet the semen, according to the theory advanced, was capable of transmitting syphilis to a fœtus that might remain in utero until full term, without danger to the mother; but as soon as born, became a centre of contagion for all non-syphilitic persons who might be so unfortunate as to have the blood or secretions from mucous patches of the child brought in contact with their absorbents; the mother, however, escaping.

The doctor believed that such doctrine set aside endosmosis and exosmosis of the syphilitic virus, and, if true, gave rise to an important question, namely, How was the absorption of the virus in cases of acquired syphilis to be explained?

When the doctrine was studied from the hereditary point of view, it was found that syphilitic mothers gave birth to syphilitic babies in instances where the father was healthy; and if the virus had not transuded through the walls of the maternal blood-vessels, when and how did the child become infected? Dr. Sturgis criticised quite extensively the cases reported by M. Kassowitz, of Vienna, who is the latest writer in support of the theory enunciated. The records of the K. K. Fündlehaus covered 400 cases; and in 122 of those, the condition of the mother had been reported as unknown. The term "unknown" was objected to, and the record shown to be decidedly opposed to the experience of Oewre of Christiania, for instance, who had reported 100 cases, and had not been obliged to give the condition, relating to syphilis, of any mother as unknown. The question upon which Dr. Sturgis's criticisms turned, was whether syphilis was conveyed to the ovum through the semen; and it was found, after examining some of Kassowitz's cases, that the conclusion that it had been, was founded partly upon the fact of the occurrence of several miscarriages, without the presence of syphilitic symptoms on the part of the mother. Interesting cases from Caspary and Langston Parker were also recited; and from them all, the doctor arrived at the conclusion that the mother's good health, in instances where she had given birth to syphilitic children, had been *only* apparent and *not real*.

Dr. Sturgis then turned to the other side of the question, where syphilitic fathers begat healthy children, so long as the mothers remained healthy. The evidence upon that point was regarded as straightforward, and although not original with, was brought out prominently by, Cullerier in 1854. Allusion was then made to cases bearing upon that side of the question, and reported by Notta, Charrier, Diday, Mireur and Oewre. In addition, Dr. Sturgis presented the records of three cases which had fallen under his own observation, and in which the evidence seemed conclusive, that mother and children remained uninfected if only the father was syphilitic; *i.e.*, that they escaped infection through the semen. Dr. Sturgis, however, regarded the question as knotty and difficult of solution, although important.

The paper being open for discussion, Dr. F. N. Otis remarked that there were many elements of doubt in all those instances reported where syphilis had been transmitted from father to child without the intervention of the disease in the mother. Those elements were so numerous, that he could not but think that many mistakes had been made, and it was to be regretted that there was no more definite method of obtaining absolute information concerning the inoculability of the seminal secretion. Until absolute results from inocu-

lation could be had, the seminal fluid being introduced into healthy persons, we should be justified in claiming the benefit of the doubt. Dr. Otis farther remarked that he was a believer in the cessation of the inoculability of the syphilitic poison. For example, a man who had passed through the active stage of syphilis, and was suffering from what are commonly called syphilitic sequelæ, perhaps at the end of four or five years, and following a thorough treatment, could not transmit the disease in any way. The mucous erosions which were sometimes seen, and which resembled very closely syphilitic processes, the doctor believed to be due to other causes than syphilis; for instance, indigestion, excessive use of tobacco, etc. With reference to the communication of syphilis from the sequelæ of the disease, Dr. Otis related a peculiar case, which illustrated the difficulty sometimes met with in obtaining reliable evidence. A man who had had the initial lesion of syphilis, followed by secondary eruptions, married a healthy woman, who gave birth to a child, which was healthy and remained so, as far as syphilis was concerned. The man had a morbid feeling that he should communicate syphilis to his wife. Time went on, and at the end of five or six years after the original chancre, the wife was brought to the doctor with what subsequently proved to be a syphilitic tubercle upon the thigh, and soon after mucous patches appeared in the mouth.

The social position of both husband and wife was, to all appearances, entirely beyond suspicion, and the case became exceedingly perplexing to the doctor. How was the presence of the syphilitic lesions in the woman to be explained? The doctor had an interview with the woman and told her his suspicions, and also, that her husband felt convinced that he was the cause of her troubles, whereupon she claimed that her husband was a model of purity, and at the same time acknowledged that she had had connection with an old lover while off upon a yachting excursion.

In closing, Dr. Otis remarked that he had never seen syphilis communicated four or five years subsequent to the active manifestation of the disease, and always doubted the reliability of the history of such reported cases.

Dr. Quackenboss regarded the transmission of syphilis as positive in one respect, viz., if a woman was syphilitic, her children would certainly be; and he was equally certain that a syphilitic father would beget healthy children in about ninety out of a hundred instances.

The doctor related a curious case, and one not easily explained.

A perfectly healthy woman married and gave birth to a healthy child; subsequently the husband gave her chancres, and the wife obtained a divorce. She was treated, and, apparently, became perfectly well; in due time she was married to a healthy man, became impregnated, and gave birth to a child unmistakably syphilitic.

Where had the poison been during the seven or eight years subsequent to the active manifestation of the disease, which finally showed itself in a distinctly syphilitic infant?

The paper was also discussed by Drs. McIlvaine, Bulkley, and Tauszky.

Telegraph Wire Extemporized for Field Surgery.—In an article with the above title, Surgeon-Major J. H. Porter (*British Med. Jour.*, May 27) describes a very ingenious method of constructing splints from telegraph wire.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, May 18th, 1876.

Dr. S. S. Purple, President, in the Chair.

ON FATTY DEGENERATION OF THE PLACENTA AS A CAUSE OF DEATH IN THE FŒTUS.

Dr. Charles A. Leale read an interesting paper upon the above subject, in which he presented certain clinical records with the view of exciting discussion concerning the proper measures to be adopted to prevent the woman from being delivered of a dead child. Fatty degeneration was regarded as the result of a defect, and not disease of the nutrient process. Such defect might be developed in connection with syphilis, phthisis pulmonalis, scrofula, apoplexy, and other conditions, and give rise secondarily to fatty degeneration. The Doctor read the histories of cases in which he had found the following changes, which had evidently given rise to such disturbances in the process of nutrition as to cause the death of the fœtus, or reduce it to the lowest grade of vitality consistent with the possibility of prolonging its life. Fatty degeneration coincident with syphilitic sperm, the mother being healthy; simple fatty degeneration following placentitis caused by blow upon abdomen; fibrinous deposits in three placentæ from a mother who had cavities in both lungs, and the father had had morbus coxarius; tuberculous placenta from a mother with cavities in both lungs; syphilitic fatty degeneration in a case in which several miscarriages had occurred within six years; apoplexy and calcareous degeneration in a healthy mother who gave birth to a child weighing 11¼ lbs. The Doctor related a case in which cancer of the cervix was present, but its growth had been retarded by the use of strong nitric acid, and the woman became pregnant. Labor was uncomplicated, the child was healthy, and no changes were found in the placenta. The cancerous growth became active six months after parturition. Dr. Leale also gave a detailed history of a case in which successive abortions had been succeeded by the delivery of a living child in consequence of labor prematurely induced.

Premature labor had been advised by Dr. Fordyce Barker as a measure to be adopted for securing the delivery of a living child; and the symptoms of alarming prostration on the part of the mother, in that particular instance, together with the feebleness of the fœtal heart, were the indications which decided the time when Dr. Leale should execute the plan recommended. The child was exceedingly feeble when born, but its life was saved by dint of perseverance in the most careful and tender nursing. The placenta was found so far advanced in fatty degeneration as to be more than two-thirds useless, there being no doubt in this instance that the life of the child would have been sacrificed if it had been permitted to go the full term of utero-gestation. The conclusions arrived at by the Doctor concerning the subject under consideration were mainly as follows:—

Fatty degeneration of the placenta was a cause of death in the fœtus more commonly than was generally supposed; its access might be insidious and its progress slow

The causes were uterine and ovarine anomalies, insufficient vitality of the ovule, disease of the ovule, insufficient vital force in sperm, disease of sperm, emotional causes, or shock causing paralysis or incomplete detachment of placenta, etc.

The varieties were tuberculous calcareous degeneration with fibrinous deposits, anæmia with atrophy, simple fatty degeneration, degeneration from apo-

plexy, scrofula, syphilis, and waxy degeneration associated with leucocythæmia.

As a measure for securing the delivery of a living child in cases in which fatty degeneration of the placenta was suspected, and constitutional treatment had failed or was not indicated, where the life of the mother or the child was endangered by delay, Dr. Leale recommended the induction of premature labor at about the thirty-sixth week of utero-gestation, in accordance with the suggestion made by Dr. Barker in the case to which allusion had been made.

The paper being open for discussion, Dr. Isaac E. Taylor remarked that the subject was one in which he had been interested for many years, and while it was true that the placenta might be the subject of congestion, inflammation, apoplexy, calcareous and fibrinous deposits, and fatty changes, the view that fatty degeneration was uniformly the cause of death in the fœtus was not generally accepted by the profession. For the child might become the seat of disease dependent upon constitutional vices of the parents, one or both, as well as the placenta, and such disease might be the cause of the death of the child rather than the changes in the placenta at the same time present. Fatty degeneration of the placenta Dr. Taylor regarded as a very common condition affecting the maternal or fœtal side, or intermediate portions, or all three together, and might be developed as a primary change in the placenta, or as secondary to constitutional disturbances. He regarded some of the cases reported by Dr. Leale as those in which the child had died in utero, and that the placental changes were secondary. Dr. Taylor related a case then under observation in which it was evident that the child had been dead ten days and yet the placental souffle could be distinctly heard. Fourteen days had been regarded as sufficient time to allow changes to take place which would arrest the souffle after the death of the fœtus. He was of the opinion, therefore, that in very many instances the retrograde changes which were found in the placenta were normal, having taken place subsequent to the death of the child, and had nothing to do with the sacrifice of its life. There were cases, undoubtedly, in which the changes that had taken place in the placenta, had directly contributed to such sacrifice, but it was not to be regarded as an easy matter to decide with reference to the measures to be adopted for the prevention of such results, especially as regarded the induction of premature labor.

Dr. Peaslee remarked that changes affecting the placenta might occur either upon the maternal or upon the fœtal side, and that it was important to determine upon which side the change had commenced. If, for example, the mother was tuberculous, and gave birth to children prematurely, and tubercles were present in the placenta, it might be reasonably inferred that the trouble was upon the maternal side entirely. If there were evidences of placentitis, it was vastly more probable that it commenced upon the maternal than upon the fœtal side, although it was not impossible for it to begin upon the fœtal; and to be the cause of fatty degeneration, it might originate upon either side. It should not be supposed, because a dead child was born in connection with a fatty placenta, that such placenta was the cause of the death of the child, for it might have been just the reverse: the child having died, the placenta became fatty. The fatty degeneration being due to diminution in the circulation, which might have its origin either upon the maternal or fœtal side, it became important in every case to determine upon which side it commenced. For, if it began upon the fœtal side it was regarded as extremely difficult to do anything to evade the disastrous consequence. We might cause the mother to inhale more oxygen, but the efficacy of the measure would be very doubtful. On the other hand, if anything could be done to improve the circulation of the mother when the change in the placenta had its origin upon the maternal side, we might perhaps succeed in saving the life of the child. But there was another question. It was supposed, for example, that a woman had had a series of miscarriages the first perhaps at the end of the third month, the second at the end of the fourth month, the third at the end of the fifth month, etc.; in such a case the doctor was of the opinion that the trouble was to be found upon the part of the fœtus, for the reason that the ovum itself was probably deceased. If the ovum—and the placenta was regarded as nothing more than a part of the ovum—became impregnated with diseased semen, it might or it might not remain alive; but allowing that in the course of time it died, the question then arose: Did it become as a matter of course true that the difficulty began upon the mother's side, or upon the fœtal side? Why did the mother develop an ovum which was cast off in one instance at three months, in another at four months? etc. What was to be inferred? Not necessarily that she was in a different condition with each succeeding pregnancy, but rather that there was some different condition in the ovum itself, or in the semen by which it was fecundated. The doctor was of the opinion that, in every case where such an experience had been developed, the difficulty commenced in the ovum, and that inasmuch as it could not be accounted for by subsequent influences upon fecundation, it must be referred to the semen, or that the father, who has had syphilis, was getting farther and farther from its effect; consequently the fœtus retained its vitality longer and longer with each pregnancy, and after a while lived to eight or nine months. Just then Dr. Peaslee raised the query whether it was a fact that a woman could be delivered of a child which had died in utero prematurely by reason of syphilis, without having the disease herself. The doctor remarked that he should in every instance in which successive abortions occurred each time at a little later period in utero-gestation, accuse the father of having had syphilis. In such cases much could be done to prevent the occurrence of the miscarriages by treating the father for syphilis, and the main idea was to get it out of the husband's system as soon as possible. At the same time it was well to give the mother assurance that she might at some future date have a living child.

With regard to cancerous placenta occurring with cancer of the uterus he had never known an instance, and he did not suppose that it would occur upon the part of the mother, although she might have cancer of the cervix preceding her pregnancy. For, the cervix might be affected by cancerous disease and the body of the uterus remain unaffected; and that was the rule. Reference was then made to three cases of cancer of the cervix in which the women did well during their confinement; there was no disease of the placenta, but the children were all very small

Dr. Joel Foster asked Dr. Peaslee whether he would induce premature labor in cases where it was quite evident that fatty degeneration of the placenta was present, having its commencement with the mother?

Dr. Peaslee replied that he should hesitate with regard to the performance of the operation; that he would be influenced by the condition of the fœtus and be ready to interfere at any time if it became necessary.

Dr. Mundé was of the opinion that the induction of premature labor at the end of the 36th week, as a general rule in cases of supposed fatty degeneration of the placenta, was not justifiable. The plan would be especially unjustifiable if resorted to for the purpose of saving a child while it was under syphilitic influences in utero. In such cases the anti-syphilitic treatment would do all that was necessary. Dr. Mundé was of the opinion that medical men were liable to attribute too much importance, in many cases at least, to the condition of fatty degeneration present in the placenta at the time of the confinement. For example, a child was born and presented a shrivelled appearance, the placenta had a pale look, was soft and flabby, and it was commonly said that it had undergone fatty degeneration. When, however, it was examined microscopically, nothing more was found than might be expected in placentæ in general, for normal fatty change commenced to take place at about the eighth month, and in some cases it became much more marked than in others without necessarily affecting the fœtus. It was not to be concluded because a placenta looked fatty that it was in an abnormal condition.

Dr. Peaslee supposed two cases and raised a question. First, suppose a woman has clearly had syphilis, had a miscarriage at the third, fourth or fifth month, and the placenta had undergone fatty degeneration.

Second, a woman without trace of syphilis had miscarriages as in the first instance, and there was fatty placenta, but in addition the husband had been known to have had syphilis.

Now, did it make any difference with regard to the treatment? Should anti-syphilitic treatment of the mother be resorted to only in the first instance, or should it be resorted to at all events?

If in the last instance a mother without syphilis gave birth to a child prematurely, and there was fatty placenta, the Doctor meant to be understood as saying that probably the child died from syphilis from the father, and not because of the fatty degeneration of the placenta. On the other hand, if she had had syphilis, and the husband not at all; whether the fatty degeneration of the placenta was caused by the death of the fœtus, or whether the syphilitic affection of the mother caused the fatty placenta, and causing the death of the fœtus the case was exactly reversed; then there would be reason for adopting the anti syphilitic treatment of the mother.

At that point, Dr. Peaslee raised another question: Had any one known of an instance where anti-syphilitic treatment had arrested a series of miscarriages occurring in a woman who had not had any signs of syphilis? If any such cases were known, he would explain them upon the ground that the anti-syphilitic treatment had acted directly through the mother upon a fœtus having syphilis.

Dr. Taylor mentioned a case in which the father was syphilitic and the mother perfectly healthy. The mother had a series of abortions at the third, fourth, fifth months, etc., and the husband died. The widow married a perfectly healthy man, and the first of her second stock of children was syphilitic, but the second and third, after the mother had been subjected to anti-syphilitic treatment, were healthy. Dr. Taylor was of the opinion that anti-syphilitic treatment should be adopted in cases in which abortion after abortion had occurred, and although it might not be successful in preventing its occurrence in all cases, in a certain number the results obtained would be most satisfactory.

Dr. Hanks recommended that anti-syphilitic treatment be adopted for both husband and wife in cases where repeated abortions had occurred, independent of displacement or other local cause.

Dr. Mundé regarded this question with reference to the effect produced upon the fœtus by remedies acting through the mother as yet *sub judice*.

Dr. Leale stated that in nearly all of his mentioned cases, the degeneration of the placentæ must have occurred prior to the death of the child, as demonstrated by diseased placentæ and the birth of living children.

Dr. Leale raised a question: A healthy woman married a syphilitic man whose sperm gave all the appearances of healthy semen when examined with the microscope, and yet conception did not take place. The husband died, the woman married again, and under such circumstances had the woman ever conceived? Had any such case been known in which conception had taken place?

On motion, the Academy adjourned.

The Coca or Cuca Leaf and its Effects.—The alleged use of this plant by Mr. Weston in his great pedestrian feats, has brought the subject before the medical profession of England, and Mr. Robert Christison and Mr. G. F. Dowdeswell have furnished some interesting facts on the properties and action of the leaf. The early history of Peru, says Mr. Christison, informs us that Cuca was used in Peru at the time of its conquest by the Spaniards. Pöppig, a German naturalist who lived in Peru for five years, after observing the habit of chewing the Cuca leaves by the inhabitants, came to the conclusion that its use is as seductive and injurious to the health, mind, and morals, as drinking or opium eating. Its victims lie in the open fields dreaming beautiful dreams, remaining out all night indifferent to cold or rains. In the end, however, the stomach gives way, the face becomes haggard, and the victim dies of all sorts of maladies. Other authorities think that the accounts given by Pöppig are much exaggerated. Dr. von Tschudi, in his visit to Peru, found it relieved the difficult breathing which is felt in ascending eminences. He thought that the moderate use of Cuca might be conducive to health. Without it, the poorly-fed Peruvians Indians would be incapacitated from performing their labor. The plant from which the leaves are obtained thrives best in the elevated forests of the Andes. In time it is covered with delicate white flowers, which are succeeded by red berries. The leaves can be stripped from the plant three times a year, and are at once thoroughly dried. When the packages of Cuca are opened, they emit a powerful tea-like odor. Mr. Christison has tried the effects of the leaves upon himself. He has taken long and fatiguing walks, living at the same time after his usual manner; then he has repeated the walks for even greater distances, and when overcome with fatigue, at some resting-place, he has chewed thoroughly, and swallowed eighty grains of Cuca. No real effects were observed until he went out of doors and resumed his rapid walking; then all sense of weariness disappeared, and he could walk, not only with ease but elasticity. At the end of the walk the pulse was 90; and in two hours fell to 72. At dinner-time there was neither feeling of hunger nor thirst, after abstaining from food for nine hours; but upon dinner appearing, ample justice was done to the meal. No unpleasant effects were felt the next day. Mr. Dowdeswell, in an article in the *Lancet* for April 29th, 1876, has the same idea as to the great and wonderful powers of endurance gained by its use.—*British Medical Journal*, April 29th, 1876.

THE ENGLISH DEBATE ON SYPHILIS.

IV.

In contrast with the admirable contributions of Sir Wm. Jenner, the remarks of Dr. Moxon are noticeable for their tedious prolixity and their sophistical character. We must express both our surprise and disappointment at this effort of a man, who, by his writings upon visceral syphilis, has heretofore commanded our highest respect. In fifty-six observations of visceral syphilis, he had found the average period of life to have been thirty-seven years, and his experience had taught him that in such cases the prognosis was not good, as the future of such patients was a short one. He differed from Mr. Hutchinson's view as to the non-specific nature of tertiary lesions, and considers that the necessity of mercury for a total cure of them proves them to be related to the secondaries. He emphasized the admission of the orator that the want of symmetry of tertiaries was really due to the condition of abundance; and considered that this, in truth, conceded the relation of both classes of lesions. While he agreed with Sir Wm. Jenner that the lesions of typhoid fever were very rarely symmetrical, he did not consider that the comparison offered by Sir James Paget, that such sequelæ of this disease as the suppuration of one rib or of phlebitis of one vein, applied at all to the distribution of tertiary syphilitic lesions. He believed that these latter lesions were often symmetrical, and cited instances of such, the most noticeable of which was that of a gumma involving each root of the vagus. He alluded to the fact that such diseases as pityriasis versicolor and trichiniasis, well known to be unconnected with blood taint, were frequently symmetrical. He further differed with Mr. Hutchinson as to the theory of the possible relation of the secondary and tertiary lesions, which we have explained in a previous number, and advanced the hypothesis that perhaps the latter attacked tissues which had not been affected by the former. In support of this, he ventured an unsatisfactory line of argument; and misapplied, in his comparison, certain well-known facts. Indeed, we hardly think he was sincere in this part of his remarks; as they convey the impression that he thought Mr. Hutchinson's theory, to say the least, untenable, if not ridiculous; and that he might, by way of pleasantry, propound one equally absurd. We must, however, credit Dr. Moxon with a happy and apposite expression in calling syphilis "a fever diluted by time."

The remarks of Mr. Thos. Smith, who opened the debate at the fourth meeting, were of a personal character and contain no noticeable point. He regards syphilis as a blood disease, and its tertiary lesions as evidences of such, thinks that secondary supplies is not very symmetrical; that the tertiary form was not always unsymmetrical in its manifestations, and did not admit that the risk of contagion ceased long before that of hereditary transmission. The simile traced by this gentleman between the course of gout and syphilis need only be mentioned as being badly taken, and not by any means conclusively proven. This being alluded to, later on by Mr. Simon, Mr. Smith said he wished merely to contrast gout with syphilis.

Sir Wm. Gull thought that if syphilis were classed with the specific fevers it should be conceded that it was not like the rest of them, limited by time. He regarded gummata as specific lesions, and that a general condition of the system was always present with them. He did not care to open the question of blood diseases, but stated his belief, that as there was no tissue in which syphilis might not produce its manifestations, it was, therefore, "a flesh and blood disease." This expression of Sir William is certainly significant and pertinent, and shows that he, as well as Sir William Jenner, look further than the majority of those concerned in the debate, in not being satisfied with the explanation of the nature of the disease on exclusively humoral doctrines. Sir William thought that syphilitic symptoms might continue throughout life, and be found in the hair, the complexion, and the odor of the sweat. The last symptom certainly appears to us to be a novel one, as caused by syphilis, yet it was spoken of by this distinguished authority as having been recognized by him, as he says he had under his care a man supposed to be suffering from tuberculosis, who "smelt of syphilis." We would commend to our readers the study of this peculiar odor, as it is a symptom which, if quickly and positively recognized, may be of much assistance in cases of doubt. It is to be regretted that we have not fuller information as to its qualities and characteristics. As might be expected, the remarks of Mr. Simon gave evidence of a profound knowledge of general and special pathology. He thought that it was impossible to draw an abrupt line between the secondary and tertiary stages of syphilis, and that we were not warranted in considering the disease as

no longer one of the blood, because the lesions cease to be symmetrical. This condition of asymmetry was probably due to a diminution in the quantity of the contagium, and of course the power was then also weakened. And the offspring of such a person might not be infected; still he would not say because a man had gummata, that he could not beget syphilitic children; nor because his lesions were unsymmetrical that he was no longer capable of transmitting the disease to his wife. His remarks upon the nature of sequelæ are striking. He says: "He could not understand such a thing as an active sequela in pathology. A passive sequela, such as a cicatrix, he could understand; but a renewed active growth was surely not, strictly speaking, a sequela. It implied, if anything, that the cause of the formation was still in operation." According to his experience, syphilis did not produce or modify other diseases. He neither rejected nor accepted Mr. Hutchinson's view of the origin of tertiary lesions, and hoped that the question could be studied in future whenever opportunity offered. He thought that much benefit might result in the determination of the ultimate results of syphilis by investigations into the family histories, and was undecided as to whether syphilis manifested itself in the third generation.

We might almost pass in silence the remarks of Mr. John Wood, as they were not of much importance. He evidently considers the two forms of sore as due to one virus. He did not consider tertiary lesions as sequelæ, thought that we could not draw a line of distinction between the two stages of syphilis, and that too much stress had been laid upon the asymmetry of late lesions by the orator. He alluded to the fact, in an inquiring way, of the mild course of syphilis in races among whom the disease had existed for years, and its severe effects when introduced into virgin soil. There is but little of interest in the brief remarks of the next speaker, Surgeon Robinson. This gentleman, in thirty years' experience in the Guards, nearly every man of whom had syphilis, rarely saw evidences of hereditary syphilis in their offspring, which condition he attributed to the early and thorough mercurial treatment which they are subjected to under strict surveillance.

Mr. E. Vonning called upon Mr. Hutchinson to explain more fully his position as to the question of dualism. He looked upon the soft sore as being placed in a category by itself. To this view Dr. Farquharson expressed his concurrence, and he further agreed with Mr. Hutchinson as regards the resemblance between syphilis and the exanthemata, and also as to the frequency of mild secondary lesions being followed by severe tertiaries. He admitted a syphilitic form of phthisis. The remarks of the next speaker, Dr. Greenfield, showed an intimate acquaintance with the histological pathology of syphilis supplemented by sound knowledge of its clinical history. His histological results are similar to those of previous observers. In their earliest stages syphilitic new growths consist of lymphoid tissue, mainly composed of round cells, developed chiefly in the outer coat or perivascular space of minute blood-vessels. The growth was at first highly vascular, and was succeeded by the development of an embryonic tissue. The peculiarity of the process was the invasion of the inner coat of the arteries supplying the growth, as so well shown recently by Heubner. This lesion of the inner coat caused or led to thrombosis and degeneration. Subsequently the growth was supplied by new vessels again. This process had been seen by Greenfield in the kidney, and he had also found gummata in the brain in secondary syphilis. He looked upon all syphilitic growths as due to the same cause, and direct expressions of the syphilitic action, and thought that the resemblance claimed between syphilis and the exanthemata was partial only; and in a concise and clear manner indicated the pathological differences in the courses of the two classes of disease. He inquired whether Mr. Hutchinson believed that every case of pegged teeth or of interstitial keratitis was one of congenital syphilis, as he believed that in some the condition might be due simply to an inherited tendency to imperfect development, or early decay of the more highly developed forms of connective tissue, which were the expression of the exhaustion of the power of connective-tissue formation. As showing the influence of the parent's condition on such development in the child, he instanced the occurrence of cretinism in children of goitrous parents during their residence in affected districts. He concludes his otherwise very able remarks by the suggestion that the evidence of the heredity of syphilis was accompanied by the date of occurrence of the specific eruption, which suggested inoculation at the time of birth or at the separation of the placenta. We look with surprise at such views from a man otherwise so sound in his knowledge of syphilis. It was our wish and hope to have concluded this analysis on this occasion; but such is impossible, as much yet remains to be considered—notably the extended reply of Mr. Hutchinson.

AMERICAN MEDICAL ASSOCIATION.

THE recent meeting of the American Medical Association was a somewhat unusual one, not only in reference to the importance of the subjects which were brought forward for discussion, but in the large attendance of delegates, and the general interest manifested in the proceedings. We present a full report in another column, and shall take the opportunity, at a future time, of discussing at length some of the more important questions which were presented at the meeting.

ST. LOUIS MEDICAL RECORD.—Dr. Wm. B. Hazard succeeds Dr. W. A. Hardaway as editor.

Correspondence.

THE "UNITY OR DUALITY OF SYPHILIS."

To the Editor of The Medical Record.

Sir:—I, for one of your readers, was much pleased to notice in your editorial on the English Debate upon the Pathology of Syphilis, contained in the issue of the Record for May 20th, your criticism of Mr. Hutchinson's dictum: "I think we may say of dualism that it is dead," etc., etc.; but it appears to me that you have failed to make a point, which has strangely escaped notice, viz., that, in spite of this statement, Mr. Hutchinson, as shown by his other writings and even by the full sentence of his which you quote, is himself a dualist of the first water.

Pray, what is the duality that has been contended for for the last twenty-odd years? Is it possible that it ever entered the mind of man that so-called dualists were advocating "duality" in the strict sense of the term? That they believed in two kinds of syphilitic virus? The mere asking of these questions would have been worthy of ridicule before the reading of Mr. Hutchinson's paper!

No, sir! The "duality of syphilis" was always a misnomer, and has always been recognized as such. It was adopted simply as a convenient mode of expression, at a time when new ideas were advanced, and little thought was given as to the most appropriate name by which these views should be known, and still less thought was entertained that any name adopted would ever be used in their attack or in their defence. *The term was adopted, not to signify a duality in syphilis, but a duality in what had been known as syphilis, and in what had been called by that name.*

Dualists have never recognized more than one *syphilitic* virus; they have simply maintained that there exists, independent of the syphilitic virus, another contagious principle giving rise to a local sore, known as the chancroid. This is exactly the position held by Mr. Hutchinson when he enunciates the "simpler creed which attributes the soft chancre to contagion with inflammatory products produced by syphilis, but not as a general rule containing its germs;" for here he recognizes the absence of the virus of syphilis, and assigns to the products of inflammation the evolution of the soft chancre (chancroid.)

It may be objected that Mr. Hutchinson has limited this power of "inflammatory products" to those "produced by syphilis;" but this limitation, if intended by its author, is incorrect, since, as is well known to every student, sores, with all the characteristics of the chancroid, have been produced by the inoculation of inflammatory products other than those of syphilis.

The only difference between Mr. Hutchinson's view and the one which has been entertained by the dualistic school, so far as I can see, lies in this:

Dualists have commonly maintained that the chancroid is dependent upon a distinct specific virus, incapable of spontaneous generation. Mr. Hutchinson believes that it is dependent upon inflammatory products, and hence that if every chancroid now existing in the world were exterminated, new chancroids would arise.

I confess that this view of Mr. Hutchinson—this modification, as it may be termed, of the view held by many dualists—has strong arguments in its favor, and may be looked upon as a step in advance. It, moreover, suggests an interesting analogy with the history of gonorrhœa during the last fifty years—a disease lopped off from what had been known as syphilis by Ricord, subsequently supposed to be dependent upon a virus of its own, now known to be a simple inflammation of certain mucous membranes. But whether the chancroid has a virus of its own or not, if it be recognized as due to a *cause distinct from that of syphilis*, then the position of the far-seeing, illustrious Bassereau has been established, for that was all that he claimed; he was wise enough to rest here without indulging in speculations; the terms "unity" and "duality" are not of his invention.

I cannot but regard Mr. Hutchinson's quiet burial of dualism as unfortunate, for I believe it will be found to have greater vitality than ever as years roll by, and it is a pity that it should be obliged to read its own obituary.

His well-deserved reputation, his great versatility of talent, his labor and zeal in the advancement of medicine and surgery, give to the words of Mr. Hutchinson unusual weight. By his announcement that "dualism is dead" many will be led to believe that we stand now in syphilography where we stood thirty years ago. For myself, I believe that "dualism" still lives, and that Mr. Hutchinson is, in fact, one of its most advanced apostles.

Yours truly, F. J. Bumstead.

24 East Thirty-eighth street, May 30, 1876.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from June 4th to June 10th, 1876.

Bache, D., Surgeon. To report to the Commanding General, Department of California, for assignmen to duty. S. O. 112, A. G. O. June 7th, 1876.

Hartouff, A., Asst. Surgeon. To proceed with companies at Fort Laramie to Fort Fetterman, Wyoming Territory, and accompany expedition against hostile Sioux. S. O. 68, Department of the Platte, June 2, 1876.

Brewer, J. W., Asst. Surgeon. Assigned to temporary duty as Post Surgeon at Fort Sanders, Wyoming Territory. S. O. 63, Department of the Platte, May 26th, 1876.

Tilton, H. R. Asst. Surgeon. Ordered before Army Medical Board, New York City, for examination for promotion, and on its completion return to his station. S.O. 112, c. s., A. G. O.

Whitehead, W. E., Asst. Surgeon. To report to the Commanding General, Department of the Missouri, for assignment to duty. S. O. 112, c. s., A. G. O.

Styer, Chas., Asst. Surgeon. Assigned to duty at Fort Porter, New York. S. O. 100, Division of the Atlantic, May 31st, 1876.

King, J. H. T., Asst. Surgeon. To report to the Commanding General, Department of Texas, for assignment to duty. S. O. 112, c. s., A. G. O.

Corson, J. K., Asst. Surgeon. Assigned to duty at Plattsburg Barracks, New York. S. O. 100, c. s., Division of the Atlantic.

Patzki, J. H., Asst. Surgeon. To proceed with troops from Fort Fred. Steele to Fort Fetterman, Wyoming Territory, and accompany expedition against hostile Sioux. S. O. 68, c. s., Department of the Platte.

Woodruff, E., Asst. Surgeon. Granted leave of

absence for one month. S. O. 102, c. s., Division of the Atlantic.

Ewen, C., Asst. Surgeon. Assigned to duty at Fort Hamilton, N. Y. H. S. O. 100, c. s., Division of the Atlantic.

Medical Items and News.

Contagious Diseases.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending June 10, 1876.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.

June 10.....	0	5	50	3	45	53	20

American Gynecological Society.—A number of the prominent gynecologists of the United States met at the Academy of Medicine, in this city, on June 3d last, and organized a "National Society for the Promotion of Knowledge in all that relates to the Diseases of Women and Obstetrics," to be called the "American Gynecological Society." The invitation for organization was accepted by the following thirty-nine physicians, the majority of whom were present: Fordyce Barker, T. G. Thomas, J. Marion Sims, E. R. Peaslee, T. A. Emmet, E. Noeggerath, W. T. Lusk, I. E. Taylor, Paul F. Mundé, New York City; John Byrne, J. C. Skene, Brooklyn; Jas. D. Trask, Astoria, N. Y.; J. P. White, Buffalo, N. Y.; Ely Van de Warker, Syracuse, N. Y.; Chas. E. Buckingham, Geo. H. Bixby, Wm. L. Richardson, Geo. F. Lyman, —— Sinclair, James R. Chadwick, D. Humphreys Storer, Boston; W. L. Atlee, Wm. Goodell, Albert H. Smith, R. A. F. Penrose, Ellerslie Wallace, T. M. Drysdale, J. V. Ingham, Philadelphia; E. W. Jenks, Detroit; W. H. Byford, Chicago; Theophilus Parvin, Indianapolis; George J. Engelmann, St. Louis; J. C. Reeve, Dayton, Ohio; Robert Battey, Rome, Ga.; Henry F. Campbell, Augusta, Ga.; Jos. Taber Johnson, S. C. Busey, Washington, D. C.; Wm. T. Howard Wilson, Baltimore.

The following gentlemen were elected officers for the present year: President, Dr. Fordyce Barker; Vice-Presidents, Drs. W. L. Atlee and W. H. Byford; Secretary, Dr. James R. Chadwick; Treasurer, Dr. Paul F. Mundé; Councillors, Drs. J. Marion Sims, Geo. F. Lyman, Wm. Goodell, T. Parvin.

The meetings are to be held annually. The first will take place in this city, on Wednesday, Sept. 13th.

Medical Advertising.—A most unprofessional method of advertising has recently come to our notice. A medical gentleman of this city has not only permitted the report of an operation for trephining to be published in one of the daily papers, with that exaggeration of its importance which is usual on such occasions, but has evidently offered more than the usual facilities to the reporter. After a detailed description of an ordinary operation, and its remarkable effect upon the sufferer, the account concludes as follows:

"Through the kindness of Dr. ——, the reporter was present on Wednesday last, when he dressed the wound. Upon removing the bandages a pulsating mass of brain substance, about the size and shape of an ordinary lemon, was discovered. The little patient sat perfectly still while the doctor applied the dressings, and did not seem to suffer any pain whatever. Around the base of the tumor the healing process is going on favorably, and the wound is gradually contracting, so that should the tumor slough away, and no unfavorable symptoms set in, the chances for the child's ultimate recovery are very strong."

This medical gentleman is a member of the medical society of this county. If there is any desire on the part of this organization to enforce its discipline, the present opportunity is one which should not be overlooked.

New York Academy of Medicine.—At a Stated Meeting of the New York Academy of Medicine, held June 1st, 1876, Drs. J. W. S. Arnold and Z. Swift Webb were elected Resident Fellows. Dr. Gouverneur M. Smith, on behalf of the family, presented a large portrait of the late Dr. Alfred Underhill, formerly Vice-President of the Academy.

Nurse-Training Establishments.—There are now in operation four schools for training nurses, two in New York, one in Boston, and one in New Haven. A fifth has been projected in connection with the Johns Hopkins Hospital at Baltimore.

Michigan State Medical Society and Homœopathy.—The editor of *The Canada Lancet*, in condemning the recent action of the Michigan State Medical Society regarding the question of Homœopathy in the University of Michigan, says: "What has the Society, or the members of the Faculty at Ann Arbor, to fear from the homœopathists and a small following of students, which is sure to become less every year? Nothing whatever. No; let them rather stand manfully at their post of duty; let them have faith in their own profession; let them be true to themselves and to those under their instruction, and let time, 'the arbiter of all things,' be judge of the result." In our opinion the editor is right. He is far enough from the centre of the fight to be beyond the mere prejudices of either side.

The Plague.—Since the 1st of January until the 21st of April, three hundred and sixty-five deaths have been reported at Hillah, and six hundred and forty at Bagdad. Although the number of cases in these two localities is decreasing, the disease is gradually spreading itself over a wide area of surrounding country, giving much cause for alarm.

Sir William Fergusson, of London, is suffering severely from symptoms indicating emphysema of the lung and hypertrophy of the heart, complicated with albuminuria.

Poisoned by Mistake.—A case of death by cyanide of potassium, which was dispensed by the druggist for acetate of potash, is reported as occurring at Rock Ferry, near Liverpool. The bottle containing the cyanide came from the wholesale house labelled "Acetate."

Cheap Doctors.—It has been for some time the practice, in the north of London particularly, for English surgeons and apothecaries to treat patients at private dispensaries for a shilling a week. As might be supposed, there is a good deal of opposition to "the shilling-a-week system" by those who desire to practice

their profession honorably. A correspondent in the *Students' Journal and Hospital Gazette* very significantly says: "What between the shilling-a-week doctors and he who systematically gives gratuitous advice, general practitioners who will not adopt such means to attract patients stand but a sorry chance to get any practice."

Medical Journals in Columbus, Ohio.—Two new medical journals have made their appearance in Columbus, Ohio: *The Ohio Medical and Surgical Journal* (bi-monthly), edited by J. H. Pooley, Prof. of Surgery in the Starling Medical College; and *The Ohio Medical Recorder* (monthly), edited by J. W. Hamilton, Professor of Surgery, and J. F. Baldwin, Professor of Physiology, in the Columbus Medical College. With two medical journals, each managed by professors in different colleges, Columbus cannot fail to keep up its reputation as one of the many medical centres in the West. Both periodicals present a creditable appearance, and contain very readable articles. The circumstance of the simultaneous issue of the first numbers proves that the profession there have suddenly awakened to the necessity of "supplying a want which," until this time, "has long been felt."

Septicæmia from an Operation.—Dr. Wilson, a surgeon of Devenport (Eng.), recently died from the effects of blood-poisoning, caused by a wound received during an operation. His elder brother, it is stated, died from a precisely similar cause in the same town three years ago.

Sir Henry Thompson, of London, has been promoted by the King of the Belgians to the rank of the Commander of the Order of Leopold, of which he previously held the rank of Knight.

A New Test for Alcohol.—Dr. Edmund Davy, at a recent meeting of the Royal Irish Academy, described a new test for alcohol:—One part by weight of molybdic acid added to ten parts by weight of sulphuric acid forms a mixture, a drop of which, added to a solution containing alcohol, instantly detects it by producing a blue discoloration.

The Vivisection Question in England.—The Royal Commission recently appointed to report upon the subject of vivisection in England, have framed a bill with the following provisions:

1. The experiment must be performed with a view only to the advancement by new discovery of knowledge which will be useful for saving or prolonging human life or alleviating human suffering; and 2, The experiment must be performed in a registered place; and 3, The experiment must be performed by a person holding such license from one of her Majesty's Principal Secretaries of State, in this Act referred to as the Secretary of State, as in this Act mentioned; and 4, The animal must, during the whole of the experiment, be under the influence of some anæsthetic of sufficient power to prevent the animal feeling pain; and 5, The animal must, if the pain is likely to continue after the effect of the anæsthetic has ceased, or if any serious injury has been inflicted on the animal, be killed before it recovers from the influence of the anæsthetic which has been administered; and 6, The experiment shall not be performed as an illustration of lectures in medical schools, hospitals, colleges or elsewhere; and 7, The experiment shall not be performed for the purpose of attaining manual skill. The exceptions to be considered are very few, and are those which refer to the impossibility of making an experiment successful and consequently useful without violating the letter of the law, which impossibility is to be certified to by the operator. The penalty for the first offence is fixed at £50, and for the second at £100, or imprisonment not exceeding three months. The bill is under discussion in the House of Lords, and the General Medical Council has appointed a committee to report upon the subject with a view to oppose legislation if found necessary.

Impure Ice and Intestinal Disorder.—Dr. A. H. Nichols, of Boston (*Seventh Annual Report of the Massachusetts State Board of Health*), gives a very interesting account of an outbreak of an intestinal disorder in a large hotel at Rye Beach, N. H., due to the contamination of the drinking-water by ice cut from a foul and stagnant pond in the neighborhood.

Dr. John O. Stone, a distinguished practitioner of this city, died suddenly June 6th, in the sixty-fifth year of his age. He was graduated in 1836 from the Medical School of Harvard College; visited Europe, and on his return was appointed a surgeon to Bellevue Hospital. In 1866 Governor Fenton appointed him a member of the Metropolitan Health Board of this city, his colleagues being Drs. Swinburne, Willard Parker, James Stone, and Mr. Jackson S. Schultz, who was President of the Board which had supervision of the Metropolitan District, comprising New York, Kings, Westchester, and Richmond counties, and part of Queens county. He retained his office until the Board was abolished in April, 1870. He was an exceedingly active and prominent worker in his position, and aided greatly in the introduction and carrying out of valuable sanitary measures, especially those relating to the ventilation and cleanliness of tenement-houses.

Sudden Death of Dr. J. V. P. Quackenbush, of Albany, N. Y.—John Van Pelt Quackenbush, of Albany, died suddenly June 8, 1876, at the age of fifty-seven years. He had been suffering for some time with symptoms of Bright's kidney and aneurism of the arch of the aorta, and was so much worn down in consequence that he temporarily relinquished his practice to spend the winter in the South. He returned to Albany in April, and feelingso mewhat stronger, resumed his practice. At noon of the day of his death he started in his buggy to make his professional calls, and when but a short distance from his office he suddenly exclaimed to his nephew, who was driving by his side, "Take care, John!" and immediately afterwards expired. Dr. Quackenbush was born in Albany, June 3, 1819, and was a descendant of one of the oldest Dutch settlers of that city. After receiving his baccalaureate degree from Williams College, he entered the Albany Medical College, graduating from that institution in 1842. Two years later he united himself with the Albany County Medical Society, of which, up to the time of his death, he was an honored and efficient member.

A careful student and indefatigable worker, he soon took a high rank among his brethren, and it was not long before he attained the object of his early ambition, the Chair of Obstetrics in the Albany Medical College. This position he held for a number of years, with great acceptability to the students and his confrères. In 1852 he was chosen President of the County Medical Society, a position which he filled with the ability and zeal for which he was noted. In 1868 he was elected President of the State Medical Society, the duties of which were executed by him in an equally acceptable and creditable manner. Another important public position held by him was that of Surgeon-General of the State under Gov. Seymour during the war of the rebellion.

He married Elizabeth Wright, daughter of Hon

Deodatus Wright. They had one child, Louisa, who was married to Lieutenant Davis of the United States Army, about a year ago, and who resides in Washington. Mrs. Quackenbush survives her husband.

At the time of his death, besides the professorship of obstetrics in the Albany Medical College, he held the positions of Attending Physician to the Albany City and St. Peter's Hospitals. For the past twenty years he has been a member and officer of the Second Reformed Church. He was regular in his attendance at divine worship and was a practical and consistent Christian. The immediate cause of his death is supposed to have been the bursting of the aneurism. Dr. Quackenbush possessed an eminently social disposition, which, combined with his remarkable cordiality, his lively humor, his high integrity, and his professional accomplishments, caused him to be loved and respected by all who enjoyed the privilege of his acquaintance. As a speaker he was eloquent and persuasive, and on more than one occasion his voice turned the tide of angry debate and secured a vote in favor of his side of the argument.

The Albany County Society, on hearing of his death, called a meeting at the Common Council Chamber. Dr. C. A. Robertson, after some introductory and eulogistic remarks, offered the following resolutions, which were unanimously adopted:

Whereas, This society has heard with surprise and profound regret that Dr. John V. P. Quackenbush, one of its most esteemed and influential members, has been suddenly cut off by death; therefore,

Resolved, That while we deplore the loss of a physician of his eminent knowledge and skill as a public calamity, we likewise painfully lament his decease as that of a kind-hearted associate, a discreet and valuable counsellor, and an honored gentleman.

Resolved, That we attend his funeral in a body, and that we wear the usual badge of mourning.

Resolved, That we deeply sympathize with his bereaved family and relatives, and that a copy of these resolutions be transmitted to his family by the secretary of the society, and also be published in the daily papers.

Remarks were also made upon the character and worth of the deceased by Drs. J. S. Freeman, Vanderveer, Bigelow, J. L. Babcock, and W. H. Bailey, after which resolutions were adopted to attend the funeral in a body.

Association of American Medical Editors.—The third annual meeting of this association was held at Philadelphia on the evening of June 6, 1876. The annual address was delivered by Dr. A. N. Bell, the President of the Association, the subject being "The Relation of the Medical Editors to the Medical Profession of the United States." In the course of his remarks he expressed the opinion that the present methods of medical instruction were so deficient that, far from advancing the interests of the profession, they were eminently calculated to promote downright quackery. To sustain this view, he quoted from announcements of medical colleges to show that the process of cramming in most of the institutions gave the student but a mere smattering of the subject gone over in the various lectures. Inasmuch as modern medicine had expanded beyond the bounds of any individual comprehension, subdivision in its study had become no less essential for its cultivation than for its practice. The specialties of a few years ago had become departments, and the attempt on the part of the professors and teachers to continue to explain the whole of the sciences now embraced in medicine to students within the brief space of time commonly allowed, had not only resulted in utter failure, but in the degradation of the profession. Referring to the report of the Commissioner of Education of the United States, he stated that the total number of schools of medicine, dentistry, and pharmacy reported to that officer for 1874, was 99; the number of instructors, 1,121; students, 9,095. Of these 9,095 students reported, 733 only were shown to have received a degree in letters or science (omitting any account of 59, out of the whole 99 institutions, which had failed to make any report on this point); and five expressly stated that in their classes there were no college graduates. The total number of volumes in the libraries of these schools, so far as appears from their reports, was only 66,611; from 44 there was no response to questions under this head, and one distinctly reported that it had none.

In conclusion, he said that medical editors had no need to wait for ceremony in the discussion of the question. Their liberty and their duty was to expose existing abuses, and, if possible, render them so odious as to make their reform a necessity.

At the close of the address a discussion was entered into in the interest of reform in medical schools. Dr. Parvin, of Indianapolis, offered a resolution expressive of approval of the preliminary course and the graded course of three years, with the stated examinations as carried out in some of the colleges, which was adopted.

The following officers were elected for the ensuing year: President, Horatio C. Wood, M.D., editor of *Philadelphia Medical Times;* Vice-President, W. H. Byford, M. D., editor of *Chicago Medical Examiner*, of Chicago; Permanent Secretary, Frank H. Davis, M.D., of Chicago.

Medical Associations in Sweden.—There are five distinct medical organizations in Sweden, which are in active and prosperous condition. The most important of these is the Medical Society of Stockholm, which meets once a week, has a large and influential membership, among which may be counted the faculty of the Caroline Medico-Chirurgical Institute. Professor E. Odmansson is the President. This association publishes not only its transactions, but also *The Hygeia*, which for a long time has been the only medical journal of the country. The Medical Society of Upsala, with Professor P. Hedenius as President, consists chiefly of the members of the faculty of the University of that place. This association, which is quite an active one, publishes its transactions in bimonthly parts. The Military Medical and Surgical Society, whose head-quarters are at Stockholm, was formed last year, and has Dr. Edholm as President. It has commenced publishing a Journal of Military Surgery, which is largely made up of the transactions of the association. The Medical Association of Gothenburg has a good and influential membership, but publishes neither journal nor transactions. The President is Dr. E. Salén, of Gothenburg. The Royal College of Health, at Stockholm, is considered to be the highest medical authority of Sweden, and has the entire medical faculty of the country under its control.

Compulsory Vaccination.—The Registrar-General of Scotland urges that the vaccination act should be amended so as to reduce the period of six months, during which an infant must be vaccinated, to four months.

Hôtel Dieu.—The new Hospital of Hôtel Dieu will probably be opened early next year.

Transverse Fracture of Patella from direct Violence.—Dr. J. H. Crawford, of Wiscasset, Maine, writes: "Noticing a case of direct fracture of the patella chronicled in reports of practice of Bellevue, I would wish to state that I have had a somewhat similar one. Miss Julia, of Metuchen, N. J., while stepping from a platform to the railroad track, slipped and fell, striking her right knee against the rail. She was conducted home, and when I saw her, the same day, I found transverse fracture of patella, with considerable displacement. I used a stimulating lotion, and the following day drew the fragments of bone together, retaining them with strips of adhesive plaster, enclosing the whole leg at oblique angle, retaining it in this position for six weeks, at the expiration of which time I commenced free motion of joint with satisfactory results. At the expiration of nine weeks the patient, for the first time since the fracture, stood on her leg, and finally had a comparatively perfect union, with free use of joint as before the fracture.

Treatment of Diphtheria.—Dr. S. H. Moore, of Syracuse, N. Y., claims considerable success in the treatment of diphtheria by the internal administration of iodine. He uses the following:

℞. Tinct. iodini ..... ʒ iv.
Sacch. alb. ..... ʒ iij.
Aquæ ..... ʒ iv.
M. Cap. ʒ i. q. ½ hor.

He writes: "I had during January and February thirteen cases, and in all of them I pursued the same plan of treatment. All the cases turned out successful, not one dying. The effect of the iodine seemed to prevent the formation of the membrane. It also prevented the swelling of the glands of the throat, and seemed to stimulate the patients, as in no one of the cases cited was there the great loss of strength that we usually find in diphtheria. The above formula is pleasant to the taste and can be retained on the most delicate stomach. The mixture at first is of the color of iodine, but during from six to twelve hours becomes almost as transparent as water."

Some Forms of Dyspepsia.—Number 16 of the *Series of American Clinical Lectures* contains an excellent article on "Some Forms of Dyspepsia," by Dr. Francis Delafield, of this city.

Chloral in Labor.—M. Polaillon maintained, at a recent meeting of the Société de Médecine, of Paris, that chloral was of use in merely combating irregular contractions, and that in general, instead of allaying pain and permitting delivery, it only relieved suffering by arresting labor.

Proportion of Medical Men to Population in England.—In the English army there is one surgeon to every 202 men, in the general population only one medical practitioner to every 1,276 men, women, and children. At the census of 1871 the number of physicians and surgeons was 14,684, under-graduates and assistants 3,116. In this country there is on the average about one physician to 500 patients, and yet we are told that there is abundance of room for the annual crop of graduates.

Drugging of Animals.—A bill has been presented to the English Parliament making it a penal offence on the part of grooms to administer poisonous drugs to horses without the knowledge of their masters. This will tend to break up a long-established and pernicious practice in Great Britain.

Epidemics of Typhoid.—The epidemics of this fever, occurring in different parts of Great Britain, are found to be due to polluted drinking-water, and its admixture with milk.

The late Dr. Parkes.—At a meeting of Army Medical Officers, held at Netley, it was decided that a memorial portrait of the deceased be hung in the mess-room of the school.

Compulsory Information of Infectious Diseases.—The Medical Society of Huddersfield (Eng.) have voted that "It is oppressive, unnecessary, and unjust that it should be made a penal offence for a medical man to fail to report the existence of infection."

Charrière.—Joseph Frederick Charrière, the founder of the great Parisian manufactory of surgical instruments, died recently of cerebral hemorrhage, in the 74th year of his age. He was born in the Canton of Fribourg, in Switzerland, went to Paris at the age of twelve, and six years later became the head of a small surgical instrument business. He began at once to attend the clinics and the operations at the various hospitals regularly, and by his skill, industry and evident desire to please, soon attracted the attention and won for himself the esteem and friendship of the prominent surgeons of the time, among others, Dupuytren, who was ever after his firm friend and counsellor. His business grew rapidly, and, instead of the forty workmen whom he employed in 1833, when he moved his factory to the *rue de l'Ecole de Médecine*, his house now gives employment to two hundred. His fame as an instrument-maker spread to all quarters of the globe, and since 1833 his instruments have taken the first prizes in countless expositions, both national and international. In 1851 he was judged worthy of the highest award at the Exposition of London, but was deprived of his prize by the narrow-mindedness of the English jury. On returning to Paris, he was recompensed for this injustice by the Cross of Officer of the Legion of Honor, which was conferred on him by the French government. M. Charrière was in his branch the foremost artist in Europe. To him we owe the present perfection of many of our most useful instruments, and, in fact, to his inventive genius are we indebted for many of the instruments themselves. He was also the first to construct the two-bladed lithotome, and without him the lithotrite might be still a dream. He was the first to substitute steel for iron in the manufacture of the instruments used in operations on the bladder. Scores of instruments that are now in daily use were improved, made lighter, stronger, more compact, and more portable by him; and for these improvements as much as for his inventions, the medical profession owe him undying thanks. Through them, not only has the skill of the surgeon been increased, but he has actually been enabled to attempt and perform hitherto impossible operations, while at the same time the sufferings of the patients and the risks of surgical intervention were greatly diminished. The work of this man was great, and its traces will long be met with. His pupils are to be found in every country, and the models of his instruments, after forty years of use, have undergone but a few unimportant modifications. He deserves to be classed with the saints of the surgical calendar, and his name should be inscribed beneath those of Lisfranc, Dupuytren, Velpeau, Malgaigne, Nélaton, Récamier, and a host of others who have honored him with their friendship and their advice.—*Progrès Médical.*

Reports of Societies.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, June 1, 1876.

DR. S. S. PURPLE, *President, in the Chair.*

ON INCISION AND DISCISSION OF THE CERVIX UTERI.

DR. E. R. PEASLEE read an exhaustive paper upon the above subject, in which he referred to the operation of incision as performed by Simpson, discission as performed by Sims, the operation which he himself performed, and the immediate and remote effect following the three varieties.

By *incision* was meant simply cutting into the substance of the cervix, while by *discission* was meant severing the cervix, or cutting through it entirely.

Dr. Peaslee employed the general term *trachelotomy*, and under that head considered the methods, the uses, the abuses, and the true value of the operation, and then explained his own method, which he believed not to be liable to the objections applicable to the operation as originated by Simpson and Sims.

As long as trachelotomy must be recognized in the treatment of stenosis of the cervix uteri, the least objectionable method, of course, should be preferred. The two methods authoritatively practised were: 1, Simpson's, or deep incision of the cervix; 2, Sims', or discission of the cervix; and 3, he added the superficial incision of the cervix, or his own operation.

First, with reference to

SIMPSON'S OPERATION:

Prof. Simpson, believing that the stenosis was most commonly found at the internal os, devised a metrotome, with which he made incisions for its removal. Dr. Greenhalgh subsequently devised an instrument for the same purpose, which was regarded as more perfect than Simpson's, because it cut more symmetrically, but at the same time cut more extensively, which was decidedly objectionable. Simpson's operation became very common, but Greenhalgh's instrument had generally been preferred. Indeed the operation became so common that, at last, it had been resorted to where no stricture was present.

The doctor then proceeded to consider the immediate and remote effects of the incision of the cervix uteri, and it was maintained that by the operation the shape, size and normal relations of the cavity of the cervix to the cavity of the body were at once changed. In some cases fatal, and, in many, profuse hemorrhage had occurred; in others pelvic cellulitis and septic peritonitis had been developed, which had proved fatal. Dr. Peaslee was surprised that such results had not followed the operation far more frequently. For, by the use of Greenhalgh's instrument, when the small incision was made, the wall of the cervix was cut more than one-half through upon both sides, while the large incision went so near through into the peritoneal cavity, that the least inclination of the uterus or the instrument, or a less thickness of the cervical wall than normal, would permit the blade to cut entirely through with the greatest ease.

In all cases in which the operation has been fully resorted to, the form and size of the entire uterine cavity, both corporeal and cervical portion, had been entirely changed, and instead of being of the shape of a flattened hour-glass, the constricted point at the internal os, it has been made bottle-shaped, with the bottom of the bottle knocked out.

Such a cavity might receive menstrual fluid from above, and seminal fluid from below, but it could not retain either. According to Sims, said Dr. Peaslee, the operation cuts altogether too extensively, but the same objection, it was maintained, also held good against Dr. Sims' operation. The immediate dangers, therefore, were hemorrhage, pelvic cellulitis, and septic peritonitis. No statistics concerning the immediate effects had been published, as they should have been.

Dr. Peaslee then noted Barnes' objection to Greenhalgh's instrument, and also cited the history of a case in which Simpson had performed his operation for the cure of sterility, when stenosis or displacement was not present, and a nearly fatal hemorrhage ensued.

But the remote effects of the operation were not to be overlooked. Admitting that dysmenorrhœa was dependent upon stenosis, what could be expected in the way of utero-gestation with a uterus that had thus been maimed? The seminal fluid could not be retained, and should conception accidentally take place, gestation would be brought to an end prematurely. The operation was seldom followed by conception, the doctor maintained; but when it did occur, abortion was the rule. And if closure of the wound occurred, the woman was not so well off as before the operation, because more or less induration would follow and might increase, and although the dysmenorrhœa might be relieved, the probability of conception and utero-gestation to the end of term was diminished. Sims had objected to the operation because eversion of the labia uteri followed; but it was claimed that the same objection held good against his own operation.

With reference to the uses of the deep incision, it could not be recommended for sterility, since it often prevented conception and favored abortion. It, however, relieved, and might cure dysmenorrhœa, if dependent upon obstruction, though the tendency, if the wound closed, was to increase the very condition for the relief of which the operation was performed.

Dr. Peaslee rejected the operation for the relief of dysmenorrhœa even when depending on stenosis, and condemned the metrotome of Greenhalgh altogether. Simpson's instrument might be useful for making incisions in the cervix to aid the removal of uterine fibroids, but under no other circumstances would he recommend it.

SIMS' OPERATION.

2. Attention was next turned to *discission* of the cervix uteri, or SIMS' OPERATION. It was first practised in January, 1857, and consisted in completely severing with scissors the wall of the cervix, upon both sides, up to the vaginal junction, after which a narrow-bladed knife was introduced into the cavity of the uterus, and the internal os divided, as thought necessary, and the opening through the canal enlarged, which had remained intact after using the scissors. Dr. Peaslee argued that by Sims' operation the cervix was annihilated for all practical purposes, and that the shape and size and value of the uterine cavity was usually destroyed. The immediate effects, therefore, of the operation, were change in the form and size of the uterine canal, frequently alarming hemorrhage, sometimes pelvic cellulitis, and septic peritonitis, which was almost invariably fatal when it occurred. The fact that the cervix was severed completely to the vaginal junction rendered the operation more dangerous, as far as hemorrhage was concerned, than Simpson's. Dr. Peaslee had known of four cases in which fatal hemorrhage followed Sims' operation, and believed that cellulitis and peritonitis were much more likely to follow Sims'

than Simpson's, because of the greater surface afforded for the absorption of any septic material. The doctor believed that, if all the fatal cases which had followed the operation had been published, the list would be startling, and it would hardly seem necessary to state that the life of the patient should not be thus jeopardized without the greatest necessity. Yet the history of two cases was selected in which the operation had been performed; but why, Dr. Peaslee was unable to tell. For, in the first instance, the woman was a maiden lady over fifty years of age, had never had dysmenorrhœa, and it was scarcely possible that it could have been done for the relief of sterility. In the second case, there was no dysmenorrhœa or constriction of the cervical canal, and it could hardly have been done for the relief of sterility, because the woman had been married only five months.

Such facts could be explained only upon the ground of a MANIA which practitioners sometimes had for performing special operations. The change produced by Sims' operation it was believed would usually relieve the dysmenorrhœa if dependent upon constriction, but it would probably prevent conception, and, if impregnation should take place, abortion would almost certainly follow. Dr. Peaslee maintained that, when such complete incisions through the cervical wall were made, they should be treated the same as rupture of the cervix in parturition, and closed as soon as possible. It was remarked that discission had been performed for the cure of flexions of the uterus, but such an operation for such a purpose was regarded as something like dividing the sphincter ani muscle for the sake of affording relief to a constriction in the sigmoid flexure of the colon. Such an operation could do nothing for the relief of a flexion except to relieve the congestion, and that would be much more safely accomplished by the application of a half dozen leeches.

Dr. Peaslee referred to the sagittal incision recommended by Sims for anteflexion, and endorsed by Barnes. It was performed by dragging the posterior wall of the cervix as low down as possible, and then slitting it up to the vaginal junction, after which a narrow knife was passed into the canal and an incision made, so as to bring the cut exactly in a line with the axis of the cavity of the uterus.

If that could accomplish all it promised, there was a better way to bring it about, said Dr. Peaslee; and then added that the operation in anteflexion was impossible; never had been and never could be performed. There was also an insurmountable objection to the performance of the operation for displacement; since, even if it could be accomplished, it ignored the very first indication in the treatment of all displacements, viz., to restore the uterus to its normal position. An incision made in the manner referred to, for the purpose of replacing a uterus, first of all left it in its malposition. But the operation did not effect what had been proposed, because in that condition of the uterus its performance was absolutely impossible. For the axis of the cavity of the cervix met the axis of the cavity of the body at an angle of 165°, and a continuation of the line of the axis of the cavity of the body would bring it through the cervical wall nearly to the vaginal junction when the uterus was in its normal position.

Now let the body of the uterus fall forward a little, and it was found that the line of the incision, being a continuation of the axis of the cavity of the body, went through into the peritoneal cavity. In the second and third degrees of anteflexion the line would not enter the vagina at all; but, on the contrary, in the third degree at least, would fall pretty well towards the woman's umbilicus.

In all cases of *flexion* or *curvature* of the cervix the operation could be performed, but that was an entirely different state of affairs, and for their relief the operation was a proper one. It should, therefore, be restricted to such cases of curvature and flexion, and never attempted in cases of anteflexion; for, in the latter condition, it never had been and never could be performed.

Dr. Peaslee then referred to the diagrams which had appeared in nearly every work published upon diseases of women within the past ten years, and had passed unchallenged. (They can be found in the last edition of Thomas's work on Diseases of Women, at pages 412 and 413.) From his study of the operation, he had come to regard them as visionary and fallacious.

With regard, then, to discission as a means of cure for sterility and dysmenorrhœa, Dr. Peaslee rejected it; and farther, knew of no condition in which it could be recommended, unless it was employed to assist in the removal of fibroids; and then the unilateral incision was, as a rule, all that was required. No statistics regarding the success of Sims' operation for the cure of sterility alone had been published.

1. Deep incision and complete discission of the cervix uteri were attended by certain immediate dangers, and were productive of certain remote consequences prejudicial to the child-bearing function of the woman. Of those there were profuse, perhaps fatal, hemorrhage, pelvic cellulitis, septic peritonitis, sterility and abortion.

2. Those risks and effects were all due to the extensive division of the walls of the cervix, and the consequent enlargement of its cavity; and with the sole compensation of relieving the symptoms or curing dysmenorrhœa, if dependent upon stenosis.

The question then arose, could such extensive division be so far avoided as to avoid these risks and at the same time remove the condition that predisposed to sterility and dysmenorrhœa?

To answer the question properly, it became necessary to study the calibre of the cervical canal, and determine the size necessary to relieve the dysmenorrhœa and favor conception.

It was laid down that the normal cervical canal in the *imparous* woman was one-seventh of an inch in diameter at the internal os, and one-fifth of an inch in diameter at the external os. The larger size of the external os had reference to conception, and had no special influence against dysmenorrhœa, since the menstrual fluid after passing through the internal os could be conveyed to the vagina without difficulty through a canal of the same size.

In the *parous* woman, the internal os remained nearly twice as large as in the imparous, and was about one-fifth of an inch in diameter, while the external os was increased in size in nearly the same ratio, and was three-tenths of an inch in diameter.

If, therefore, an internal and external os existed of these sizes, the woman would be insured against sterility and dysmenorrhœa. Now, to obtain that size required an incision only $\frac{1}{35}$ of an inch in each direction at the internal os and $\frac{1}{70}$ of an inch at the external os, to convert the ora of the virgin into the ora of the parous woman. Practically, it was believed to be well in some cases to make the incision deeper, but if there was no congestion, the depth of the incision noted was regarded as sufficient. Now, to secure the required calibre of the cervical canal and internal os, Dr. Peaslee, in cases where the stenosis was slight and the cervical canal soft and pliable, had been in the habit of employing a series of steel conical dilators. But about ten years ago he had devised a measure which was more prompt

and less painful than dilatation, and less dangerous than either Simpson's or Sims' operation. The operation consisted in making a superficial incision; it had for its direct object the removal of the stenosis of the cervical canal, and nothing else, and the rules which governed its adoption were embraced in the following propositions:

First, with reference to the *internal os*.

1. If a sound $\frac{1}{8}$ of an inch in diameter passed easily, there was no stenosis, hence no incision was required. One-fifth of an inch in diameter was the size of Dr. Peaslee's largest conical dilator and his large sound.

2. If a sound $\frac{1}{8}$ of an inch in diameter passes, there was no absolute necessity for an incision to relieve the stenosis. But there might be stenosis for the passage of fluid, though not for the passage of a sound; and under such circumstances an incision might be required.

3. If a sound $\frac{1}{8}$ of an inch in diameter passed, and gave no evidence of stenosis, no incision was required.

4. If a sound $\frac{1}{8}$ of an inch in diameter could not be passed, there was present either stenosis, or, what was more probable, one of the flexions. Prove, therefore, in every case, before operating for stenosis, that the obstruction at the internal os, to the free passage of the sound, one-eighth of an inch in diameter, or more, was not due to flexion.

Second, with reference to the external os.

5. If a sound $\frac{1}{8}$ of an inch in diameter could be passed, there was no stenosis. But if there was congestion of the lining membrane of the cervical canal, there might be stenosis, practically with reference to conception, and an operation might be required.

6. If the external os admitted a sound only $\frac{1}{8}$ of an inch in diameter, there was probably stenosis with regard to conception, and an operation might be necessary.

7. In case the operation was performed, it was important to retain the fusiform shape of the cervical canal as far as possible.

Dr. Peaslee then showed his metrotome for the performance of the operation he described.

The incision should be carried only to such an extent as would give the precise average relations of size found in the cervical canal of the parous woman. In cases complicated by congestion, a larger opening might be required, and the limits might extend beyond $\frac{1}{8}$ of an inch in diameter, for the internal os, and perhaps to $\frac{1}{4}$ of an inch for the external os. Dr. Peaslee's operation then consisted mainly in making a *superficial* incision in the cervical canal, sometimes not extending through the mucous membrane, and sometimes a trifle more, as already indicated. It should be performed at least four days after or six days before the catamenial period; and, by preference, the small blade of Dr. Peaslee's instrument should be used, for the calibre of the canal could be easily increased with the dilators, and by so doing the liability of union of the wound was diminished. No anæsthetic would be required, and the amount of hemorrhage seldom exceeded two drachms. He had never known of pelvic cellulitis or peritonitis following the operation, because the medullary portion of the cervix had not been disturbed. His observations were based upon about 300 operations. The woman should be kept in bed for two or three days, and not permitted to walk for a week.

Sometimes it might be necessary to repeat the operation; but, in all the cases where he had been obliged to repeat it, Simpson's or Sims' operation had previously been performed, and the incision had closed. In such cases, the cicatricial tissue was so firm, that repetition of the incision usually became necessary. Nor had the operation been followed by sterility or miscarriages, as had the other operations, and it had very often cured the sterility, and the dysmenorrhœa of stenosis. It was, therefore, an operation that proposed all the advantages of the others, and without their dangers. In conclusion, Dr. Peaslee suggested that both Simpson's and Sims' operations should be rejected for the treatment of sterility and dysmenorrhœa, and that some better method should be employed, of which, perhaps, his own was merely a forerunner.

In the discussion which followed the reading of Dr. Peaslee's paper,

Dr. Fordyce Barker remarked that he believed it to be high time that the subject under consideration was discussed, and that the opinions and practices of the leading gynæcologists of the city should be known and understood. He argued that it would doubtless relieve the profession from some reproach, and vindicate it from a dangerous under-current of belief, that the leading practitioners of the city of New York regarded slitting open the cervix uteri as the grand panacea for all uterine disease, not only for the cure of local troubles, but formed a therapeutical measure for the cure of hysterics, nymphomania and all allied maladies.

In certain cases, doubtless, the operation was required, but as a general thing it was not necessary. About twenty years ago Simpson presented a hysterotome to Dr. Barker, and the first two operations he performed were followed by conception, and the children were carried to term. The next twelve cases were cured of the dysmenorrhœa, but the sterility remained. Since that time the doctor had closely watched professional opinion with reference to the operation, and had also seen patients in an extremely dangerous condition from loss of blood following the operation; and his experience enabled him to verify the correctness of some of the statements made by Dr. Peaslee with reference to the unnecessary performance of the operation.

The operation should never be performed except for stenosis, either congenital or acquired. Acquired stenosis might come from displacement; but there were many cases of displacement which were not attended by either sterility or dysmenorrhœa. Many such patients, however, had been treated for displacement, when no treatment whatever had been necessary. The doctor then related a case, and the woman had had three or four miscarriages since the performance of the operation. Dr. Barker remarked, in conclusion, that he had not performed the operation in a single instance in all his hospital practice, but that he had occasionally performed it in private practice.

Dr. Emmet coincided with the general doctrine advanced in the paper, and also in the remarks made by Dr. Barker, adhering, however, to the view that the operation of discission was proper in cases of flexure and curvature of the cervix.

Dr. Pallen was inclined to the opinion that the operation was justifiable, and much more frequently called for than one might be led to infer from the paper by Dr. Peaslee.

Indiana State Medical Society. The twenty-sixth annual meeting of this Society was held at Indianapolis, May 16th and 17th. The following officers were elected for the coming year: Dr. S. S. Boyd, President; Dr. E. D. Laughlin, Vice President, and Dr. G. V. Wolven, Secretary. In the course of the meeting a resolution was adopted to the effect that no paper be published in any medical journal before its appearance in the Transactions, which we believe is a great mistake.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, May 10th, 1876.

DR. C. K. BRIDDON, PRESIDENT, IN THE CHAIR.

PERIOSTEAL TUMOR OF THE ORBIT.

DR. H. KNAPP exhibited two specimens, taken partly ante- and partly post-mortem, from a patient who had been under his care for the previous three or four months. The patient, a male, aged thirty-six years, who was emaciated and pale, stated that during the war he became affected with syphilis, since which time he was never healthy. There was a stellate scar upon his forehead and a depression in the bone upon the right side of the head, and altogether he presented a cachectic appearance. Two years ago his right eyeball began to protrude, and a year ago his sight began to fail. Then the upper lid commenced to swell at the inner part of the orbit, and finally a tumor began to make its appearance at that point.

In that condition he consulted Dr. K. The exophthalmus was so considerable that the eyeball was almost dislocated forward, and it was only with the greatest difficulty that the lids could be closed. Considerable chemosis present. Pupil movable when other eye closed. Media clear. Fundus showed typical appearance of choked disc. On the inner side of orbit was a soft, uneven, somewhat nodular tumor. Eyeball moved upward and outward, but not inward. The patient complained of considerable pain. Dr. K. advised the removal of the tumor and the preservation of the globe. To this the patient consented. An opening was made through the inner part of the upper lid, the conjunctiva incised, and the tumor exposed. It was found to occupy nearly the whole of the orbit. The globe was easily pushed aside. The inner rectus was detached, and soon afterwards the optic nerve was cut across at the apex of the orbital pyramid. The tumor was found to have sprung from the periosteum, and was removed by scalpel and gouge as cleanly as possible down to the bone. The antrum was open, but seemed to be clean. It could not be made certain that the tumor did not extend into the infra-orbital fissure. At the completion of the operation the ball was replaced, the lids stitched, and an examination made. The whole inner side of the eyeball was insensible. On ophthalmoscopic examination there were found a certain number of retinal veins still filled, notwithstanding that the posterior ciliary arteries were cut in the division of the optic nerve. After the operation the patient did well enough for two or three days, when he complained of headache and obstinate vomiting, which symptoms continued until his death, on the thirteenth day. The examination of urine during life showed only the least trace of albumen. On the third day after the operation an ulcer developed itself on outer half of the cornea. This was quite a remarkable circumstance, inasmuch as the outer half of the eye was sensitive and the inner half not. The inner half of the cornea was perfectly clear, and through it the examinations could be made. The ulcer spread by the fifth day so as to involve the lower part of the cornea, and finally perforated the same on the twelfth day. The fundus oculi showed a somewhat whitish red appearance. Upon the third or fourth day new retinal vessels made their appearance, that is to say, the old retinal vessels were filled again. About the eighth day there was a good deal of retinal venous hyperæmia, and the background began to be reddish again.

Dr. Heitzmann assisted at the post-mortem examination. The brain was normal. The orbit, with contents, were removed from the cranial cavity. Optic chiasm was normal—no evidences of meningitis anywhere. The liver contained a small fibrous gumma, as did also one of the testicles. The spleen was lardaceous. The kidneys very much enlarged and the seats of acute croupous inflammation. The latter was evidently the cause of death.

The microscopic examination of the eye showed that the tumor sprang from the periosteum of the orbit and entered somewhat into the lower orbital fissure The tumor was of a sarcomatous character, and was in connection with the sheath of the optic nerve only at the apex of the orbital pyramid, and at that point the nerve was compressed. The bundles of nerve fibres were filled with sarcoma cells, while the inter-vesicular substance was free from them. This appearance continued not only through the whole extent of the nerve, but also into the cribriform membrane into the eye, filling the intra-ocular end of the optic nerve, and there producing the symptoms of choked disc.

SALPINGITIS, WITH ANOMALOUS SYMPTOMS.

DR. ROBERT NEWMAN exhibited the uterus and fallopian tubes removed from a virgin, aged thirty-two years. During the summer of 1874 she caught "cold," and was attacked with menorrhagia, from which she suffered continuously for fifteen months, during all the time being without treatment. She then consulted Dr. Newman, who tried every means to check the hemorrhage, dilating the uterus with sponge-tents, etc., but without avail. Finally a single application of acetate of zinc and glycerine proved effectual. After the hemorrhage ceased she had transient œdema, first of one lower extremity and then of the other. Her anæmia continued, and she showed no sensible signs of improvement. Dr. Fordyce Barker was called in consultation, but nothing new was discovered in her condition, and the treatment of chlorate of potash, iron, and quinine was continued. She continued to grow weaker, and without any other symptoms finally died.

At the autopsy Douglas' sac was filled with matter, but there were no adhesions, and the intestines were perfectly free. The right fallopian tube was occluded, and its extremity was distended by a cyst the size of a small hen's egg. This occlusion was supposed by Dr. Newman to be the result of inflammation, while the cyst was filled by the accumulation of inflammatory effusions and of menstrual discharges. The kidneys were healthy. The left lung showed that the immediate cause of death had been pulmonary œdema.

LESIONS IN COLLES' FRACTURE OF RADIUS.

DR. E. MASON presented the wrist-joints of a boy, aged twelve years, who had died of fracture of the base of the skull two hours after the receipt of the injury. Both wrists were the seat of Colles' fracture, and the specimens were of interest as showing the peculiarities of the lesion in a recent case. Both radii were fractured, and one wrist looked as if there was also a dislocation of the ulna. The left wrist showed a diastasis of the radius with a comminuted fracture of the epiphysis. The right radius showed a diastasis, with very little displacement. There was no rupture of either of the posterior radio-ulnar ligaments, and there was very little displacement of the triangular ligament. There was no dislocation of the ulna.

FRACTURE OF NECK OF FEMUR AND FALSE JOINT.

Dr. Mason also exhibited the neck and upper portion of the femur removed from a patient who died in the Roosevelt Hospital. The patient was a large, fleshy single woman, sixty years of age, admitted Jan-

uary 26th. She had fallen the day previous and had produced a fracture which was readily diagnosticated as intra-capsular. She was treated in the usual manner, but was seized with meningitis on the 14th March last, and died of the same on the 28th March. The post-mortem examination of the injured hip showed that the neck of the femur was almost entirely gone, and that there had been very little, if any, attempt at reparation. When she was admitted she informed the house-surgeon that twenty years before she had fallen on the other (right) hip and produced a fracture there, for which she was treated. On autopsical examination of this hip the following condition of things was discovered: The head of the bone was loose in the capsule. The neck of the femur had entirely disappeared, and a facet had been formed between the greater and the lesser tuberosity upon which the head of the bone played.

Dr. Mason also exhibited the head, neck, and portion of the shaft of the femur of a colored woman, aged 60 years, showing nature's effort to heal a fracture below the trochanter. The patient during the time of the treatment was suffering from dropsy, due to Bright's disease, and from bed-sores. With great care she recovered from the fracture, but died ten months after from perforation of the sigmoid flexure. The union of the bone was complete, and the usual buttresses existed between the angle of the shaft and neck.

He lastly exhibited a specimen, illustrating the reparative power of nature in uniting a fracture under difficulties. It was a femur removed from a woman aged seventy, who died of pluro-pneumonia forty days from the time of the reception of an oblique fracture.

TUBERCULOUS DISEASE OF TESTES—EJECTION OF PROSTATIC FLUID SIX MONTHS AFTER THEIR REMOVAL.

Dr. Leale completed the history of tuberculous disease of the testicles, specimens of which had been presented to the Society six years ago. The patient was then aged thirty-nine years, and received an injury of one of the testicles by the tilting of a chair upon which he was partially seated. The organ was driven up into the inguinal region, and it was with difficulty replaced in the scrotal sac two hours afterwards. It swelled rapidly, giving him a great deal of pain. He made use of household remedies for two weeks, when he consulted Dr. Leale. Despite of treatment the testicle gradually grew larger, and in the course of a few weeks the testicle of the opposite side became involved. Becoming very much emaciated, and the disease assuming a malignant character, one testicle was extirpated, followed in a few days by the removal of the opposite one. Dr. Delafield found that the glandular substance had been replaced by tuberculous material. The first testicle weighed a little over six ounces, and the second five. After the operation his general health improved and he grew quite strong.

At the time of the presentation of the specimens Dr. Flint asked the question whether there were any evidence of tuberculous disease in the lungs, stating that primary tubercular degeneration of the testicle was very rare. The answer was that there was no such disease of the lung as could be detected at that time.

Six months after the removal of the testicles the patient stated to Dr. Leale that he was able to eject semen during copulation. Dr. Leale expressing his doubts on the subject, the patient stated that he had taken occasion to withdraw, and had ocular demonstration of the fact. On this occasion about half an ounce of fluid was discharged, which was prostatic in character.

The patient had five children previous to the operation.

In relating the circumstance to the N. W. Medical Society, one of the gentlemen present stated that he owned a gelding in which he noticed the same condition one year after castration. After six months the power of ejecting the fluid failed in the patient, he continuing to grow fat and increase in strength. Being the trainer of Weston, the patient exerted himself beyond his powers of endurance, the result of which was exhaustion, followed by anasarca, from which he never recovered.

At the autopsy tubercles were discovered at the upper portion of each lung, and in the substance of the kidneys, liver, and spleen. The pancreas was almost entirely destroyed by the disease, and was adherent to the surrounding parts. Dr. Leale had no doubt that the deposits in the testicles were of a secondary character to those in the lungs, although the small amount of disease in the latter, and the absence of symptoms pointing to the same, made a diagnosis uncertain.

COPPER COIN IN INTESTINAL CANAL FOR SEVEN WEEKS—FINAL PASSAGE OF THE FOREIGN BODY PER ANUM.

Dr. Leale also presented a specimen, which was a copper coin 2⅝ inches in circumference which had been swallowed by a girl three and a half years old, and retained seven weeks in the alimentary canal. At first the foreign body was lodged in the upper part of the œsophagus, but in efforts at extraction with a probang it was pushed into the stomach. About four days after, Dr. Leale believed that he detected the coin in the right ilio-cœcal region. Here it remained for five weeks, giving rise to frequent attacks of pain and of violent tenesmus. At the end of this time the patient almost fainted while at stool. The mother thought that the penny had passed, but on examining the discharge found that she was mistaken. According to the mother's statement of the child's symptoms, and the seat of pain, the coin must have become lodged in the rectum, just above the sphincter. Finally, two weeks after, the foreign body was discharged in a hardened stool. It is unnecessary to state that during the time that the penny was supposed to have been lodged in the rectum Dr. Leale was not in attendance upon the case, and hence the child was unrelieved until the occurrence of the stool in question.

Dr. Mason remarked that it was not unusual for geldings and oxen to discharge prostatic fluid six months after castration, and that eunuchs were sometimes enabled to do the same thing. In most cases of castration the penis was apt to grow disproportionately large.

EXSECTION OF WRIST-JOINT FOR CARIES.

Dr. Briddon presented carious bones removed by the operation of exsection of the wrist joint. The following was a history of the case:

Wm. G. Harrison entered the Presbyterian Hospital (service of Dr. Briddon), April 19th, 1876. He is thirty-nine years old, a deaf-mute, married, cooper by occupation, and a man of temperate habits.

Previous history.—A tumor made its appearance on the back of his right hand three years ago. It was painless, and grew slowly, and was probably ganglionic in character, as he states that in October, 1875, attempts were unsuccessfully made to rupture it. It was subsequently removed by a cutting operation, and whilst recovering from the effects of this he fell and sprained his wrist; this was followed by swelling of the hand and forearm, which necessitated the use of incisions, which discharged for a long time. Patient

then entered a hospital, where he remained from Oct. 28th, 1875, until April 16th, 1876, when amputation was proposed and rejected.

Present condition.—General health good; his right hand is swollen, fingers extended, stiff, and incapable of motion; concavity of palm effaced, and on its surface are the openings of two fistulous tracks that communicate with carious bone; there is very slight motion at the wrist-joint, none at the metacarpo-phalangeal and phalangeal articulations; all the anatomical points are masked by hard brawny infiltration. Believing, with Professor Lister of Edinburgh, that any partial removal of the bones involved would only lead to progressive destruction of the remainder, the operation devised and advised by that gentleman was proposed and accepted by the patient.

Operation, April 27, 1876, in presence of the Staff and Class.—An incision was commenced over the middle of the back of the second metacarpal bone; it was carried upward in a line with that bone to the carpo-metacarpal articulation, and then midway between tendons of thumb and index as high as the inferior border of the radius; the tendons of the thumb were drawn outwards, those of the common extensor inwards, the knife being kept in close contact with the bones. Then an incision was made on the inner border of the hand, reaching from two inches above the styloid process of the ulna to the middle of the metacarpal bone of the little finger; these incisions permitted all the soft parts to be separated from the bones on both palmar and dorsal surfaces, and gave abundant room for completing the subsequent steps of the operation, and in this dissection it was found that the os magnum had disappeared entirely, and that the contiguous bones were carious and more or less fused by anchylosis. All the carpal bones, the basis of the metacarpal, the inferior articulating surfaces of the radius and ulna, were removed; the cartilages of the latter were intact; but, in consonance with the views of Lister, they were all carefully removed. No tendons were injured save those inserted into the carpal bones themselves, and after removal of Esmarch's bandage, which had been used during the operation, it was not found necessary to apply a single ligature.

Dressing.—A long dossil of lint was allowed to traverse the centre of the cavity; a few interrupted sutures at either extremity of the incisions, and a straight splint.

28th.—There has been but very inconsiderable oozing, which was controlled by elevation of the limb. Swelling slight, reaction moderate, and general condition good.

29th.—Two yards of lamp wick were placed in a vessel containing weak solution of carbolic acid suspended over the limb; one end of this wick was carried through the wound from side to side, and thence over the edge of the bed so as to insure effectual irrigation of the part, and the parts were enveloped in a solution of the same. These precautions were deemed more advisable, inasmuch as erysipelas had developed in a patient in the same ward who had been subjected to a rhinoplastic operation.

May 1st.—Patient is in excellent condition; traumatic fever has entirely subsided; his tongue is clean and appetite is good; locally everything looks promising; there is very little swelling, and the drainage is effectual.

May 10th.—Everything has done remarkably well; the limb, or rather forearm, is one inch shorter than its fellow, and the parts involved are consolidating; distance between truncated radius and ulna and metacarpal bones is about an inch and a quarter; a drainage tube traverses the part, and the limb is supported on a Palmar splint, reaching from the elbow to the ends of the fingers, with a hinge opposite metacarpo-phalangeal articulation, which permits the digital portion of the splint to be dropped to permit of passive movements.

A CASE OF MORBUS COXARIUS, SHOWING THE VALUE OF EARLY OPERATION.

Dr. A. B. Crosby presented the hip-joint of a patient who had died of hip disease, for the purpose of showing what nature would sometimes do for such cases.—Anchylosis had taken place, and the other evidences of the disease, having advanced to the third stage, were present. The result of a careful examination on the part of Drs. Sayre and Crosby created the opinion that the disease was practically cured, and excision was not advised. Notwithstanding, however, every effort to improve the general condition of the patient, he sank and died.

At the autopsy the anchylosis was found almost complete. The tissues surrounding the joint were apparently healthy, but there were two or three distinct openings communicating with it. One of these, on the outer and external portion of the joint, passed in front of the anterior inter-trochanteric line, the pus from which burrowed three or four inches downwards, discharging itself on the inside of the thigh. Another opening was found on the roof of the acetabulum, through which a great deal of pus had escaped, the greater part of the discharge finding its way into a pocket beneath the pubes capable of holding three or four ounces. In order to show the condition of the interior of the joint, a button of bone was removed from the anterior surface. On removing the plug and looking into the cavity of the joint, a portion of the carious head of the femur was seen, separated but firmly imprisoned. Here then was a case which, left to nature, ended in death, but which the removal of the dead bone would have cured.

In remarking upon the general treatment of morbus coxarius, Dr. Crosby said that the disease was the most manageable of any which the surgeon might be called upon to treat. The time when the operation should be performed was, in his opinion, as soon as the head of the bone had become carious.

Dr. Sayre stated that his experience had proved to his satisfaction that cases of hip disease, when left entirely to nature, resulted in shortened and deformed limbs, with more or less anchylosis.

SARCOMA OF THE LARYNX, PHARYNX, AND NARES—TRACHEOTOMY—DEATH.

Dr. Delafield presented the larynx, pharynx, and portion of the tongue removed post-mortem from a woman aged 67 years. She was admitted in Roosevelt Hospital, March 2d. Four months before, the cervical glands of right side commenced to enlarge; soon after which a small tumor made its appearance on the right side of the tongue, gradually extending over its base, and involving the whole of the pharynx and posterior nares as far as could be seen. Dr. Weir removed a portion of the growth on the 7th of March. During the administration of ether the patient came so near choking to death that tracheotomy was performed. She recovered from the operation, but on the 13th of March she was attacked with bronchitis, and died on the 24th.

At the autopsy it was found that the base of the tongue, the entire wall of the pharynx, the posterior nares, and part of the epiglottis, were involved in a

new growth, which also infiltrated itself into the soft tissues of the neck and cervical glands. The lungs were the seats of lobular hepatization of a gangrenous character, besides showing distinct gangrenous spots which were probably caused by the inspiration of gangrenous portions from the tumor of the mouth. Although presenting the clinical history of epithelial cancer, it contained no epithelial elements whatever. Its structure was sarcomatous and resembled that variety which have their origin in the lymphatic glands. Dr. D., in conclusion, stated that he had never seen a tumor of that structure growing exactly in that way in this region, nor did he know of any.

Dr. Heitzmann remarked that he had seen a similar case.

Dr. Robinson referred to the case of sarcomatous tumor of the larynx which he had already reported to the Society, and which was the only one of its kind on record.

Progress of Medical Science.

On the Accessibility of the Duodenum to Operation.—Dr. Braune has come to the conclusion that the so-called vertical part of the duodenum is accessible to operation from behind, to the entire avoidance of the peritoneum, which it is known only partially covers the anterior surface. The experiments and observations, which he details, were made upon bodies carefully hardened by chromic acid and alcohol injections, and by freezing. He states that, as a rule, the right kidney stands somewhat higher than the lower end of the perpendicular portion of the duodenum, and that the lower and inner wall of this portion is behind the peritoneal sac. He performs the operation on the cadaver as follows: The body, being turned face downwards, an incision is made from the region of the posterior superior spinous process of the ilium, above and close to the right of the median line, to above the twelfth rib. The muscles are divided successively until the sacro-lumbalis is reached. This being pulled aside toward the median line with hooks, the quadratus lumborum appears, and must be split through. Hugging the vertebral column, the lower border of the right kidney is made free, the twelfth intercostal nerve and artery are cut across, the ureter and inferior vena cava pressed to the inner side, and the kidney upwards. The intervening connective tissue being now separated with forceps, the wall of the duodenum on the median side can be recognized, when an incision about two inches long may be made in it.—*Archiv der Heilk.*, May 1, 1876.

Salicylic Acid and Oil of Thyme.—Dr. E. Bälz, of Leipsic, assistant to Prof. Wunderlich, emphasizes the following points regarding the administration of salicylic acid and the oil of thyme: The former, especially in women, may give rise to various symptoms referable to the nervous system, notably excitement and jactitation. It is a decided diuretic. Sweating may be absent, even when its anti-febrile action is most marked. It is no prophylactic against fever. Its effects are usually marked in acute articular rheumatism, though it may not prevent relapses. The salicylate of soda may be given hypodermically in solution, but its administration is very painful. The oil of thyme cannot take the place of salicylic acid, as it has the disadvantages of the latter and not its good qualities, and is also very expensive. Its febrifuge action is no more certain, in equal doses, than that of salicylic acid. On the other hand, its taste and smell are very distasteful to most persons. It tends to produce diarrhœa, and in sensitive persons disagreeable symptoms referable to the nervous system, similar to those of salicylic acid.—*Archiv der Heilk.*, May 1, 1786.

The Operative Treatment of Meteorism.—Prof. Fräntzel, of Berlin, in the *Charité Annalen* for 1874, discusses the subject of operative relief for meteorism, where it reaches such a degree as to be dangerous from diminished respiratory capacity, and from over-distention of the intestinal walls. He has practised puncturing the intestine with an exploring needle in ten cases, doing it from two to seven times in several of them. Of these cases, two died from peritonitis referable to the punctures, and one from laceration of the intestine, starting from the seat of puncture, and allowing the escape of fæces. He therefore concludes that this practice is not allowable, except in cases where peritonitis already exists.—*Centralbl. f. Chir.*, No. 17, 1876.

On Massage.—Dr. Von Mosengeil, of Bonn, at the close of an extended article on the Practice of Massage, gives this estimate of its availability in surgery. Its value must be recognized, though the best results will be obtained by the few who will bring to its use abundant time, patience, skill and strength. It is not adapted for every-day use by every physician, nor will it be much used in hospitals, from lack of time. Specialists, therefore, will probably get the most satisfactory results from it.—*Archiv f. Klin. Chirurg.*, xix. 4, 1876.

Cancer of the Testicle in an Infant.—A healthy child, eight months old, was recently brought to M. Depaul on account of a solid cylindrical tumor situated in the left side of the scrotum. It was continuous with the cord, and measured 1½ inches in length by ¾ inche in width. The skin was movable over the tumor, and there was no effusion into the tunica vaginalis. There was neither pain nor tenderness. Soon afterwards the skin of the scrotum became red and adherent to the tumor at one point, where later on an abscess opened spontaneously. Through the fistulous opening about one-third of the tumor escaped and formed a hernia. Castration was performed without an anæsthetic, when the child was ten months old. The operation was easily performed; the cord was rapidly divided by an écraseur, and there was neither primary nor secondary hemorrhage. Fifteen days after the operation the wound had almost entirely cicatrized. The tumor, immediately after the operation, presented a wrinkled appearance in the part involved in the hernia, but was smooth in the rest of its extent. On section it presented a yellowish white color, and a cancerous juice was obtained by scraping. Microscopical examination proved it to be a cancer, but of a mixed composition; in one part it was sarcomatous, while the greater part was scirrhous.—*La France Médicale*, May 13, 1876.

Gastrotomy.—The Record has already published a notice of M. Labbé's operation for the removal of a fork from the stomach of a man, but a few additional points may be interesting to our readers. The operation of gastrotomy has now been performed nine times for the removal of foreign bodies, and in all nine cases it has been successful. On the other hand, it has been performed nineteen times for cancer of the œsophagus, and three times for traumatic stricture of the œsophagus, and in all these cases ended fatally within a period varying from a few hours to twelve

days. In a great many of these cases there was no peritonitis, but probably in all the operation had been delayed until the patients were in the last stages of exhaustion and cachexia.

M. Labbé, previous to his operation, made many dissections to determine the point of election for the incisions. He found that the great curvature of the stomach never ascends higher than a transverse line drawn between the cartilages of the ninth ribs. The end of the cartilage of the ninth rib is situated immediately above the first depression that is met with on passing the finger downwards along the border of the false ribs. This depression is bounded below by the movable cartilage of the tenth rib, which gives rise to a peculiar crepitus when moved. Having settled these points, M. Labbé made his incision parallel to, and half an inch to the inside of the edge of the false ribs on the left side. The incision was 1¾ inches long, its lower extremity falling upon the transverse line between the cartilages of the two ninth ribs. The rectus muscle was not cut, and the stomach was opened at the junction of the cardiac and pyloric portions.—*Gazette Hebdomadaire de Méd. et de Chir.*, May 8.

Salicylic Acid in Acute Rheumatism.—Three articles appear in the *Boston Med. and Surg. Journal* upon this mode of treatment. Dr. Towle reports seven cases. In one, a man twenty-seven years of age, who had been suffering three weeks from acute rheumatism, salicylic acid was given in ten-grain wafers, every hour, until seven powders were administered. He then became so excited and delirious, with no improvement of the rheumatism, that the medicine was discontinued. In another case, the same dose was given every hour, until the patient had taken two drachms. After the seventh powder was taken, the swelling and pain had sensibly subsided. After the ninth dose there was a great deal of buzzing in the ears. Twenty-four hours after the commencement of the treatment, all the symptoms had disappeared, and active motion of the affected part caused no pain. The dose given in all his cases depended upon the age and general condition of the patient. From his experience he thinks that salicylic acid is of decided value in acute rheumatism; and the more acute the case, the more certain the success by using it in full doses. Dr. Huse gave to a man of thirty, the subject of repeated attacks of acute rheumatism, two grains of salicylic acid in sugar every hour for about twelve hours, when the pulse fell below 100 and the joints became more mobile. Two grains of the acid were then given every two hours. The treatment was continued until one drachm had been administered. Three days after the attack, the patient was walking the streets, the rheumatism having disappeared. Dr. Hodgkins reports a case of a young woman who had a severe attack of acute rheumatism in the left knee; where he commenced with five grains of the acid every two hours, which amount was repeated the next day every hour. On the fourth day she was well, and able to walk about without any stiffness or pain. There was no nausea, but when the dose was increased to five grains an hour there was some dizziness, profuse perspiration, and an increased flow of urine.—*The Boston Medical and Surgical Journal*, May 25, 1876.

A Rare Fracture of the Upper Extremity of the Tibia.—Mr. Duplay reports the following interesting case. A workman, aged 60, was injured by the sudden fall of a wall that was in process of demolition. On the next day the foot, leg, and lower third of the thigh were swollen, with considerable tension of the integuments, under which there was an enormous bloody infiltration. There was also effusion into the knee-joint. The leg was parallel to the plane of the bed and in a straight line with the thigh, but just beneath the patella there was a sudden depression, that looked as if it had been produced by a blow of a hatchet. The leg could be moved freely in both lateral directions, but without crepitus, and it could be elevated so as to form an angle with the thigh, but the depression still remained. Crepitus could only be obtained in front of the head of the fibula, where there was a small fragment of bone completely detached. The femur, patella, fibula, and articular ligaments were not injured. Extension failed to reduce the deformity, but a partial flexion brought the shaft of the tibia into proper position with the broken fragment. The limb was maintained in this semi-flexed position by means of a cuneiform pad and a few turns of bandage, but on the next day the dorsum of the foot was found to be cold and discolored, and the leg as far up as the knee covered with bullæ containing sero-sanguinolent fluid, and the dressings had to be removed. There was no pulsation in the posterior tibial artery. The leg was then put on a double inclined plane, and subsequently simply laid on its outer side on the bed; but nevertheless gangrene set in; and the patient died of pneumonia complicated by cerebral troubles on the thirteenth day after the accident.

The autopsy revealed old meningitis of the convexity, and extensive pneumonia. The leg was the seat of a vast gangrenous phlegmon, and the fractured ends of the bone were bathed in a bloody and purulent effusion, which extended into the knee-joint. The popliteal and anterior tibial veins were ruptured, and the popliteal artery compressed by the broken fragments of bone, and its lumen further obstructed by a fibrinous clot. The head of the tibia above the tubercle was broken into four fragments—a middle, an internal, and two external; the middle, which was also the largest fragment, comprising the insertions of the crucial ligaments. Several of the lines of fracture extended into the knee-joint. The femur, patella, and fibula were not injured.

This is certainly a rare variety of fracture, and surgical literature contains but few examples of analogous injuries. It was not produced by direct injury, for the integuments were not broken, and the patella, its ligaments and the condyles of the femur, were not injured, but probably by a sudden and forcible extension, so to speak by an effort at *anterior flexion*, in the course of which the large median fragment, containing the insertions of the crucial ligaments, was torn from the shaft of the tibia. The displacement backwards of the upper fragments was probably due to the weight of a stone falling on them at the moment of the injury.

In the treatment of similar injuries a position of semiflexion which will replace the tibia in the axis of the superior fragment will best fulfil the indications. It must be remembered, however, that all fractures of the upper extremity of the tibia unite but slowly and with difficulty, which is more marked the nearer the fracture approaches the joint, probably because the solution of continuity affects a spongy and very vascular tissue, and the effusion of blood between the fractured ends is always considerable.—*Le Progrès Médicale*, April 29th.

University of Michigan.—To the medical colleges of New York who have consented to receive the tickets of the University of Michigan, that of the University of the City of New York is to be added.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

THE ENGLISH DEBATE UPON THE PATHOLOGY OF SYPHILIS.

V.

Having presented in brief the essential points of the opening paper of the debate upon the Pathology of Syphilis, at the Pathological Society of London, as well as those of the remarks of the various speakers, it now only remains for us to consider the speech of the president of the society and the summing up of the orator, Mr. Jonathan Hutchinson. The remarks of the president, Mr. George Pollock, contained no noteworthy point, being rather a series of interrogatories addressed to the next speaker, rather than a presentation of facts. It is evident that, like that of many of the participants in the discussion, the gentleman's knowledge upon the subject is of a general and practical character, and that he has not paid especial attention to its study. He attributes very little importance to the division of the disease into stages, and is not certain as to the precise period at which its contagion ceases, though he thinks that hereditary transmission is possible in the tertiary stage. He alluded to the fact that surgical lesions of continuity often remained ununited owing to a tertiary syphilitic condition. He did not agree with Sir James Paget as to the sequelæ of fevers, and thinks that those of typhoid are of pyæmic nature and often symmetrical. After congratulating the society upon Mr. Hutchinson's paper and the debate, he called upon that gentleman for his reply. The latter reviewed the various leading points brought out in his opening, and pronounced himself in the most emphatic manner as a believer in the cryptogamic nature of syphilis. Seeing that previously he had not clearly formulated this view, the suddenness of the avowal is somewhat startling. It must be conceded that his course was either wise or lucky, for had this aspect of the question been developed as a feature of the opening, we are not certain where the debate, which was very long indeed, would have ended. Though his opinion is strongly expressed, it is evident that his ideas are by no means mature or clear. His view, that the existence of a syphilitic yeast or *contagium vivum*, as causing syphilis, offers the best and most rational explanation of the phenomena of the disease, is obviously open to the most serious criticism, and shows that he is almost exclusively wedded to the humoral doctrines of pathology, as applied to syphilis. He still thinks that the analogy between the course of syphilis and the exanthemata is well taken, not having been shaken by the remarks of some speakers, which, he says, dealt with opinions rather than facts. He reiterates the statement that, as a rule, syphilis, when uninfluenced by treatment, is tolerably orderly in its course, while that of the exanthems is far from being as regular as we are accustomed to think. We cannot here follow Mr. Hutchinson in his remarks as to the state of the blood as modified by the syphilitic germs, and shall only repeat more precisely the fact that he thinks that the principal processes take place in that fluid, and that the rôle played by the tissues in these diseases is only secondary. It is readily seen that this view opens the way to extended comment and analysis, such as indeed are precluded by the nature of this notice. It seems strange that, among so many eminent pathologists, the great import of Sir Wm. Jenner's suggestion, that syphilis is a *flesh and blood* disease, was not fully appreciated, and that the doctrines therein embodied did not seem to be familiar to them. It may here be suggested that if the doctrine of a ferment in syphilis is admitted, the analogy between it and the exanthemata must be, to a greater or less extent, conceded; but when it is urged that, perhaps, certain specific proliferative changes take place in the tissues themselves, and that from them, by the medium of the blood, the disease is perpetuated and communicated, the analogy, to say the least, is weakened, and a line of argument is established, which was, as we have shown, only hinted at by one or two speakers, and by Mr. Hutchinson rejected. Indeed we have reason for the suspicion that he did not appreciate the full significance of the train of facts embodied in Sir Wm. Jenner's suggestion. Thus it will be seen that, with this cardinal point unconsidered, nearly all the remarks were a practical concession of the analogy; hence that we are, at the end, exactly where we commenced. We very much regret this result, as the occasion was a rare one, and much could have been said as to the place of syphilis in nosology. It is true that some light has been thrown upon the nature of the sequelæ of certain blood diseases, but as to that of the tertiary lesions we have had little added, other than opinions; so that, in his reply, Mr. Hutchinson expresses his theory as to their simple nature, and as to their being tissue derivatives from pre-existing specific lesions, with more emphasis than he did in his introduc-

tory. In this connection we may say that we, for many reasons, wholly repudiate this hypothesis, for we look upon it as simply a theoretical expedient rendered necessary by the doctrine of ferments just considered. Passing now to practical questions, Mr. Hutchinson calls attention to the fact that contagion generally occurs within the first two years of the disease, and that various clinical facts go to show that the blood does not retain its infective properties but for a few years. He allows syphilitics to marry at the expiration of two years after the disappearance of the last syphilitic symptoms. Mr. Hutchinson makes clever use of the germ theory to explain late hereditary transmission of syphilis, by saying that, perhaps, the germs remain latent in the testes and ovaries for a longer period than in the blood. This shows the weakness of the humoral theory, as it is an unequivocal concession that the elements of the disease remain latent in the tissues themselves. It seems curious that an observer of his ability and a thinker of his powers should thus stultify himself to the import of facts which is clearly apparent, merely to preserve the symmetry of a theory. We shall not follow the argument of the orator as to the nature of infantile syphilis, as it is really a piece of special pleading in favor of his yeast theory, with an evident intent of throwing ridicule on the tissue theory, as expressed by Sir Wm. Jenner in the term "potentialities of development." It is very clear that Mr. Hutchinson is so far biased by his blood and yeast hypothesis that he cannot or will not admit any other view. The result is to very much impair the value of his summing up. Mr. Hutchinson's remarks upon the effect of a syphilitic fœtus upon the mother, are interesting, if not thoroughly orthodox in their teaching. He alluded to the fact, long ago spoken of by Colles, that women bearing syphilitic children were not by them infected, and stated that no exception had been brought forward. In explanation, he thinks that a modified form of syphilis is given to the woman, in which there is a protection to her from severe manifestations, and which is unattended with cutaneous lesions. He compares its nature to that of vaccination. It will be seen that this is a direct admission from him that the fœtus can infect (though in a qualified manner) the mother. But, further on, he declares himself a believer in the doctrine that syphilis may be derived from the father alone, while the mother escapes, and promises further information on this point. The rest of his reply was simply in answer to certain minor issues raised by the various speakers, and it contains nothing noteworthy or important. Those of our readers who have followed us in our brief presentation of this debate, will see that, while it has suggested many points, much has been left untouched, while some of the direct issues raised by the orator have been left in much the same state as before the debate. We have already exceeded our limits, and cannot now review critically the whole discussion, which was in many parts too long and wordy. We may, however, derive some benefit from its perusal, and we have the satisfaction of knowing that it can be rendered profitable to future debaters on this subject, in pointing out to them errors which they can avoid. In this connection we would remark that it can hardly be expected that a subject like syphilis, which, for its thorough discussion, requires special study and observation, can be very minutely handled by men who have only observed it in a general and practical way.

PATENT RIGHTS IN MEDICINE.

The allusion by the President of the American Medical Association to the subject of patent rights in medicine will doubtless tend to bring it before the profession for discussion. Although the principle upon which that provision of the Code is founded which makes it derogatory to the dignity of a medical man to hold a patent is an eminently proper one in spirit, it has long been felt that its strictly practical application has been more or less detrimental to the true interests of inventive genius. The mere fact that because the inventor of any particular apparatus is a medical man, he should receive no pecuniary benefit for his time, study, and labor, is certainly a very absurd method of proving the justice or utility of a law which makes such provisions. The primary object of all inventions directly or indirectly connected with the healing art is for the benefit of humanity, and so long as the object is attained the medical man should be remunerated by the consciousness of contributing his mite to the relief of suffering. He has no desire, neither has he the right, to withhold any of such benefits from his profession or his patients for mere pecuniary consideration; in other words, it is the duty as well as the privilege of every medical man to aid his professional brethren all he can, and not hamper them by any legal restrictions of royalty in the exercise of their functions. So far, the provisions of the Code should be considered absolute and beyond question.

The case is so different, however, with any invention which can also be used in other arts, that we see no reason why the medical man should be debarred from the exercise of the usual privileges of ordinary men. Because any given apparatus is used in medicine without restriction, there is no reason why, if it may be employed in the arts, the inventor should not receive all the pecuniary benefit which such a use might confer. Many inventions of this sort have been made by medical men for strictly medical purposes, and have afterwards been patented by outsiders for adaptation to other purposes. Certainly this is very unfair to the real inventor, and calls for some more reasonable interpretation of the spirit of the Code than at present appears to exist.

It is claimed by instrument-makers that no advantage is taken of inventors in their efforts to develop the

resources of our art, and that no more than the ordinary profit is made on new instruments or apparatus. This is as it should be, and so far as strictly medical or surgical appliances are concerned the inventor must be satisfied. When these instruments can be used or otherwise appropriated, and incomes can be derived from their sales, the inventor certainly has the right to protect his interests by a patent. Here, it strikes us, the line should be drawn, and the provisions of the Code should be so modified as to make it possible to distinguish between a strictly medical patent and the patenting of a medical invention to be employed for other than medical purposes.

THE NEW YORK ACADEMY OF MEDICINE.

WE call the attention of all interested in the prosperity of the New York Academy of Medicine to the remarks of Dr. Gouverneur M. Smith at a recent meeting of that body. This organization, with the commendable spirit of founding a home for the profession of New York, has secured to itself an elegant building, and has done everything which energy of purpose can effect and earnestness of good intention can direct to place it upon a substantial basis. So far its efforts have been attended with a flattering success, but the running expenses of the establishment, together with the present debt upon the building, are such as to call for pecuniary aid which shall lift it into a higher sphere of usefulness. When it is considered what a comparatively small sum is necessary to attain this laudable object, we are quite ready to believe that the appeal will not be made in vain. In no better way can the medical interests of this city be centralized, and its common professional good advanced.

Reviews and Notices of Books.

CLINICAL LECTURES ON DISEASES OF THE HEART AND AORTA. By GEORGE WILLIAM BALFOUR, M.D., St. And., F.R.C.P. Ed.; Physician to and Lecturer on Clinical Medicine in the Royal Infirmary, Edinburgh. Philadelphia: Lindsay & Blakiston, 1876.

THIS book contains the essence of Clinical Lectures delivered by Dr. Balfour, on cases of diseases of the heart and aorta that have fallen under his observation during the last eight years. In the seventeen lectures presented, 424 pages, the following subjects have been considered: The general diagnosis of cardiac diseases; incompetency of the aortic valves, with reference to the diagnostic significance of the murmurs, progress of the disease, prognosis and treatment; murmurs and other physical signs distinctive of mitral stenosis, curable and incurable; curable mitral regurgitation and its treatment; tricuspid regurgitation, curable and incurable; pulmonary murmurs and their signification; variation and vanishing of cardiac murmurs; intermittency and irregularity of the pulse, and palpitation; secondary results of cardiac disease; angina, and fatty heart; pericarditis, myocarditis, and hypertrophy, apart from valvular disease; remarks upon the action of digitalis, and the general therapeutics of cardiac disease; malposition of the aorta simulating aneurism; aneurism, and its treatment by iodide of potassium.

The general rules to be observed in making a diagnosis of cardiac disease are elaborately, and, for the most part, clearly stated under the head of peculiarities of the pulse, inspection, palpation, percussion, and auscultation. In this connection, the author states that "of all the signs of cardiac disease murmurs are those most usually confided in, yet they are really those of least value." This statement is based upon the fact, that endocardial are closely simulated by exocardial murmurs, and that real valvular murmurs may disappear either temporarily or permanently. To this the author admits of but a single exception, which has reference to the auricular-systolic, or the so-called pre-systolic mitral murmur. Every other murmur must be simply noted, and afterwards duly considered in connection with the probabilities, when the examiner makes up his estimate from evidence obtained by inspection, palpation and percussion. This is an important principle in physical diagnosis, and were it more generally recognized by the profession, it might be the means of lifting the great depression which has settled upon many patients who are supposed to be the subjects of grave cardiac disease. There is, however, a greater or less probability that any valvular murmur may be connected with actual cardiac disease, and this fact must always be borne in mind. For example, the author states that persistent accentuation of the pulmonary second sound, independent of pulmonary disease capable of producing congestion, is an invariable indication of cardiac valvular lesion.

With reference to the manner in which murmurs are produced, the author adopts the theory that they are due to the sonorous vibrations of fluid veins produced in the current of blood, but at the same time states that just how these sonorous veins are produced, and how they may be modified remains yet to be explained.

The author, while discussing the terms auricular-systolic and pre-systolic, as applied to the murmur indicative of mitral stenosis, refers to the writings of Drs. Leaming, Donaldson, and Flint, of this country, and combats the teaching of the first two gentlemen upon this point.

Dr. Balfour maintains that, although it may not be practically important whether the sound is produced when the auricle contracts or during the soundless portion of the systole of the ventricles, yet clearness and accuracy in teaching cannot be imparted without directing special attention to its rhythm. He believes that want of accuracy in this respect has led so experienced an observer "as Professor Flint to describe as pre-systolic, murmurs which must have been diastolic in rhythm." Dr. Balfour states unhesitatingly when a pre-systolic mitral murmur exists, contraction of the mitral orifice is invariably present, notwithstanding Prof. Flint has reported three cases in which there was present a pre-systolic murmur, and at death no lesion was found at the mitral opening, but lesions which gave rise to aortic insufficiency. The author claims that Prof. Flint has evidently erred in timing the rhythm of the murmurs in the cases he has reported; "for a murmur depending on aortic regurgitation is always diastolic, and therefore has a rhythm very different from a pre-systolic murmur. But even without timing these murmurs, they have each of them such a distinctly different character that no one perfectly acquainted with the pre-systolic murmur could ever mistake a diastolic aortic murmur for it." The latter portion of this statement is rather free-handed, and

we can scarcely understand how it is to be reconciled with the statement made by the author in another part of the volume, when he speaks of Prof. Flint as an observer "who has had much experience." In Chap. VI. the author refers to a curable mitral regurgitant murmur, associated with such diseases as typhus and enteric fevers, chorea, anæmia, chlorosis, etc. He also recognizes the existence of curable and incurable tricuspid regurgitant murmurs; and the most common cause, next to mitral stenosis, for these murmurs, is said to be bronchitis, acute and chronic.

While discussing angina pectoris, arsenic is recommended as the remedy most entitled to confidence as a prophylactic against cardiac neuralgia. To prevent irritation of the bowels, it should be combined with opium, or administered in smaller doses, as "it not infrequently happens that systems which are sensitive to the injurious action of drugs, are also sensitive to their curative action." For the relief of the attack, the author speaks with positiveness upon his estimate of the value of chloroform. It is maintained that there is no diseased condition of the heart which should deter the physician from the cautious use of this agent.

"The thing desired in angina pectoris," says the author, "is to free both cardiac muscle and cardiac plexus from the influence of the depressing agent, whatever it may be, which gives rise to the sub-paralysis on the one hand, and to the neuralgic pain on the other; and this can be done only by narcotizing the nervous centres, through which the reflex action takes place, and thus set the heart free." For this purpose chloroform is to be preferred above all agents, and is regarded as perfectly safe. He administers it from a smelling-bottle containing a piece of sponge.

Just how Mr. Balfour reconciles the following statement is somewhat mysterious even to Yankee ingenuity. He says: "Rheumatic pericarditis, worthy to be called so, is almost unknown to us;" and a little further on, "if we take cardiac pain, accompanied by slight, but still detectable effusion into the pericardium, or by friction about the base of the heart, accompanying acute rheumatism, as signs of rheumatic pericarditis, as they undoubtedly are, then I do not suppose that my percentage has been at all, if in any respect, less than that of my neighbor's."

The author believes that the nutrition of the cardiac muscle is increased by the action of digitalis, and that this is accomplished by increasing the force and duration of the heart's systole. He also claims that the iodide of potassium has the power to relieve the symptoms of aneurism in a most remarkable manner, independent of any other treatment whatever; but that its success, as a matter of course, will be materially promoted by adjuvant measures.

The author is perfectly certain that there is no remedial agent at the present time which can so surely give relief, so certainly prolong life in cases of aneurism, as the iodide of potassium. This work is illustrated, although the cuts are the least important feature. Taken as a whole, it is a book well worthy of being placed in the library of any physician.

LECTURES ON NURSING. By WILLIAM ROBERT SMITH, Resident Surgeon Royal Hants Co. Hospital. Phila. Lindsay & Blakiston. 1876. 12mo.

THIS little work comprises a course of lectures delivered to the Nursing Staff of the hospital, with which the author was connected. The subject is treated in a very comprehensive manner, for such as wish to become practically familiar with the duties pertaining either to medical or surgical nursing. For such it can be read with interest and studied with profit.

RARE AND CURIOUS MEDICAL WORKS—MEDICAL BUREAU OF THE NAVY—PHOTOGRAPHS OF U. S. NAVAL HOSPITALS—MEDICAL ASSOCIATIONS AND SIGHT SEEING.

PHILADELPHIA, June 17, 1876.

I CALLED attention in my last letter to the various literary treasures of which the Model Army Hospital, in its exhibit at the Centennial Exposition, gives a merely introductory glimpse. Perhaps no more favorable opportunity will be offered than the present for a detailed reference to the curious and rare attractions which are here illustrated photographically. While thus alluding to the albums containing photographic representations of title or other pages from many valuable books in the National Medical Library, collected by the Surgeon-General and his assistants, we at the same time give an insight into the contents of the library itself, which has not yet been as fairly and fully appreciated by the masses of the profession as its great merits entitle it to. The expensive catalogues, as published, are of course only distributed to a few, while the profession at large seems scarcely to realize the extent of the resources that are placed within their reach. Lovers of rare and curious old books will be gratified at an inspection of the sample pages, even though they be but photographic fac-similes, detailed in the following list, all of which form a portion of the exhibit of the Army Medical Department. In addition to those given in my last letter, I may mention the following as being among the most venerable in this wonderful collection. "Aggregator de Medicinæ Simplicibus of Jacob Dondus Paduanus." (Folio, probably printed at Strasburg by J. Mentelia, about 1470. The editio princeps. Valescus de Taranta "De epidimia et peste." (Probably printed at Argentorati about 1470.) "Liber de complexionibus, proprietatibus, electionibus operationibus que laxativarum. Practica de Medicinis particularium ægritudinum," by John, son of Mesua. Venice. 1471. "Manual of the practice of medicine, by Arnold de Villa Nova." (According to Brunet, it is printed with type used at Mantua in 1473.) "Regiment der jungen Kinder." (Augsburg in 1473.) "Pandects of Matthew Silvaticus." (Folio, probably printed at Strasburg about 1475.) Edito princeps of the "Summa conversationis et curationis" of William de Salicet. 1476. "Tractatus de Regimine Sanitatis" of Benedictus de Nursia. Bononia. 1477. "First edition of Celsus." Florence. 1478. "Canon of Avicenna," folio. Patavia. 1479. "Artzneibuch" of Ortolff von Beyrlant. Augsburg. 1479. "First edition of the works of Petrus Argelata or de la Cerlata." Edited by M. Moretus. Venice. 1480. (The initial letters are illuminated.) Anatomy of Mundinus. (Without page or date.) Regimen Sanitatis of the School of Salernum. With the Commentary of Arnold de Villa Nova. 1480. First edition of the "Liber de Medicina" of Averroes. Venice. 1482. Rare edition of the works of Mesua. Venice. 1484. Treatise on poisons of Petrus de Abano. 1487. "Practica" of Valescus de Tarranta. Lyons. 1478. First edition of the "Liber Theicrise" of Avenzohar. Venice. 1490. "Ortus Sanitatis" of Meydenbach. Moguntia. 1491. (The figures are colored.) The collection of medical tracts known as "Articella." Venice. 1493. Treatise on medicine of Arnold de Villa Nova. Ve-

nice. 1494. "Lilium Medicinæ" of Bernard de Gordon. Venice. 1496. Tractate on Syphilis, by Grunpeck de Burckhausen. (Probably printed at Augsburg. 1497.) Treatise on syphilis of John Widman. 1497. Treatise of Gaspar Torrella on syphilis. Rome, about 1498. Treatise of Jerome of Brunswick on epidemics and the pest. 1500. (Contains some very curious and spirited woodcuts.) Fasciculus of John de Ketham. Venice. 1500. Commencement of an anonymous treatise on the pest. (Prior to 1500 A.D.) "Practica nova medicine" of John de Concoregia. Venice. 1501. Treatise on anatomy by Mundinus. 1507. "De Swangern frawen und hebammen Rosegarten," by Eucharius Roeslyn. Argentorati. 1513. (The original edition. In Latin it is the "De partu hominus" of Eucharius Rhodion, and is translated into English by Raynalde under the title of "The Woman's Book.") Collection of medical tracts. Venice. 1508. Works of Albucasis. Augustæ-Vindelicorum. 1519. Treatise of Ulrich de Hutten on guiac and syphilis. Bononia. 1521. Aldine edition of Galen. Venice. 1525. "Secreta Secretorum" of Aristotle. 1528. Aldine edition of the Greek text of Paulus Ægineta. 1528. A pamphlet of four leaves on the sweating sickness. Printed by Anthony Peypus, the younger. 1529. Treatise of Bertholomeus, "De proprietatibus rerum." London, Thomas Berthelet. 1535. Collection of pamphlets on syphilis. Basel. 1536. Vesalius' "De humani corporis fabrica, libri septem." Basileae. 1543. First edition. (Plates engraved under the direction of Titian.) Copy of an autograph poem by Philip Melancthon, "De considerationc humani corporis." Written on the fly-leaf of the copy of the first edition of Vesalius' "De humani corporis." Treatise on medicine by Gonetius Pereira. 1558. (A very rare book.) The first medical journal printed in German; being a translation of the "Journal des nouvelles découvertes" of Nicolas de Blegny. 1680. "Zodiacus medico-gallicus." A reprint in Latin of the first French medical journal—the "Journal des nouvelles découvertes," by de Blegny. 1685. A volume containing many water-color drawings of monsters, with MS. descriptions.

In addition to the works already enumerated there are photographs of about fifty other treatises on surgery and American medical history in the National Library, which, from their rarity, also deserve to be mentioned. I am disposed to devote considerable space to this portion of the exhibit of the Army Medical Hospital, for the very reason that your readers may never have so opportune a guide to the contents of the Library as that which I now offer them, and because in the modest little corner assigned to these albums, the latter may be very readily overlooked by the casual visitor. Here may be seen photographs of pages from "The noble experyence of the vertuous handywarke of surgeri," a translation of the "Hantwerck" of Jerome of Brunswick. London. 1525. "Practica in arte chirurgica" of John de Vigo. Lyons. 1521. "Hantwerck der Cirurgien," by Jerome of Brunswick. Utrecht. 1535. Alphonsus Ferrius, "De Sclopetorum sive archibusorum vulneribus." Rome. 1552. "Feldtbuch der Wundtartzney," by Hans von Gersdorff, called Schylhans. Franckfurt, A. M. 1551. First edition of the "Dix livres de la chirurgio" of Ambrose Paré. Paris. 1561. Commencement of the "Historiall Expostulation against the Beastlye abusers, bothe of Chyrurgerie and Physicke," by John Halle. Printed with his translation of the "Chirurgia parva Lanfranci, lanfranke of Mylayne, his briefe. London, 1565. First edition of the Treatise on the pest, small-pox and measles, by Ambrose Paré. Paris. 1568. First edition of the "Deux livres de chirurgie" of Ambrose Paré. Paris. 1573. Portrait of Ambrose Paré. From the folio edition of his works in French. Paris. 1575. (The first edition.) Manual of Surgery of Schylander. Antwerp. 1577. "Officinne et Jardin de Chirurgie Militaire" of Le Lievre. Paris, 1583. "Certain works of Chirurgie compiled by Thomas Gale." London. 1586. English translation of "Arceus." London. 1588. "Cirugia Universale of Gio. Andrea della Croce." Venice. 1605. "Treatise on Gunshot wounds" of Francis Plazzoni. Venice. 1618. First edition of the "Treatise on the Movements of the Heart and Circulation of the Blood," by William Harvey. Franckfurt. 1628. "Hoplocrisma spongus, or a sponge to wipe away the *weapon-salve*," by William Foster. London. 1631. "Viaticum" of John Woodall. London. 1639. "Institucion of Chyrurgerie," by Thomas Gaille. London. 1567. "La Grande Chyrurgie" of Guy de Chauliac. Bordeaux. 1672. "Severall Chirurgicall Treatises," by Richard Wiseman. London. 1676. "Treatise on Surgery" of Matthew Godfried Purmann. Franckfurt und Leipzig. 1692. Treatise of Purmann, containing fifty cases of gunshot wounds. Franckfurt und Leipzig. 1721. First edition of the Treatise of Park on Excisions of the Joints. London. 1783. "Reflexions sur les playes," by C. F. Faudacq. Namur. 1735. "Treatise on wounds" of J. D. Schlichting. Amsterdam. 1748. "Traité des plaies d'armes a feu," by M. Desport. Paris. 1749. "Collection of observations in the Military Hospitals," by Richard de Hautesierck. Paris. 1766. (One of the most valuable works in connection with the history of Military Surgery in France, and very rare.) "Joyfull newes Out of the New-found Worlde," being a translation of "Monardus," by John Frampton. London. 1596. Thatcher's "Brief rule to guide the Common-People of New-England how to order themselves and theirs in the Small-pocks or Measles." Boston. 1677. (From an autotype reproduction of the original broadside sheet in the Library of the Massachusetts Historical Society.) "Principia Medicinæ" of Ossorio. Mexico. 1685. Inaugural Thesis of William Bull, of South Carolina, "De Colica Pictonum," Leyden. 1734. (Bull was the first American graduate of Medicine.) Treatise of William Douglass on "The Practical History of a New Epidemical Eruptive Miliary Fever with an Angina Ulcusculosa Which Prevailed in Boston, New England, in the years 1735 and 1736." Boston. 1736. Inaugural Dissertation of John Moultrie, of South Carolina, on the "Yellow Fever." Edinburgh. 1749. (Dr. Moultrie was the first American graduate at Edinburgh.) Essay on Inoculation, by Laughlin Maclean. Philadelphia. 1756. Inaugural Dissertations of John Morgan. "De puris confectione," Edinburgh. 1763. "On Medical Schools in America," by John Morgan. Philadelphia. 1765. Of Benjamin Rush, "De coctione ciborum in ventriculo." Edinburgh. 1768. Of James Tilton, one of the first graduating class at the Medical College of Philadelphia. Philadelphia. 1771. Of Jonathan Potts and of Jonathan Elmer of the same class. Inaugural Dissertation of Peter De Sales la Terriere, on "Puerperal Fever." Boston. 1789. (Being the first printed Medical Dissertation of the University of Cambridge.) First number of the Medical Transactions of the Massachusetts Medical Society. Boston. 1790. "Journal of the Practice of Medicine," etc., printed at New York about 1790 (?). Being a reprint of a portion of the "Military Medical Journal" of De Horne. A Pamphlet of "Certificates of the efficacy of Dr. Perkins' patent metallic instruments." Newburyport. 1796. Treatise of James Tilton on Military Hospitals. Wil-

mington. 1813. First volume of the Ohio Medical Repository. Cincinnati. 1827. (A very rare medical journal.) "Journal de la Société Médicale de la Nouvelle, Orleans." New Orleans. 1839. (The first medical periodical published in the South; very rare.) Confederate States Medical and Surgical Journal. Richmond. 1864. (The only medical journal published in the South at this date.)

The Medical Bureau of the Navy makes a very modest display in the south-eastern portion of the U. S. Government building, but sufficient to exhibit its resources for usefulness in peace and war. Medical Director Joseph Wilson is in charge, with whom is associated Passed Assistant Surgeon F. V. Greene. Here may be found several handsome show-cases filled with medical stores and supplies, drugs, instruments, stationery, bottles, plasters, medicine cups, medicine chests, surgeons' note and report books, etc., etc. The object has been to exhibit the necessary outfit in all these items for a ship of five hundred men. Included in the medical stores for this number are 147 different articles. The general surgical armamentarium includes a variety of splints, sponges in profusion, numerous operating cases, with an additional "general operation case" of imposing proportions, "expeditionary cases," batteries, instruments for treatment of affections of the eye and ear, and of the genito-urinary organs, an autopsy case, dental instruments, microscopes, and the various modern guides to diagnosis, such as the laryngoscope, ophthalmoscope, etc. The older or retired surgeons of the present day have lived long enough to remember how scantily the navy of their younger days was supplied with all these mechanical aids and ready servants of the practitioner, which the department now liberally and judiciously places in their possession.

Around the walls are large framed photographs of the various U. S. Naval Hospitals at Mare Island, California; Chelsea, Mass.; Norfolk, Brooklyn, Washington, Annapolis, and Philadelphia. Unlike their brother officers in more conspicuous branches of the service, the surgeons, however deserving or however active they may be, but rarely come to the surface for public praise or notoriety, and we do not wonder therefore that the walls are barren, so far as their adornment with the features of naval medical celebrities is concerned.

Among the other articles in this exhibit may be mentioned a bedstead with a woven wire mattress, giving the advantage of good ventilation, cleanliness, and elasticity. There are also a fan of four revolving blades turned by the hand, for ventilating the lower parts of a ship in hot weather; and an acrater for distilled water. Next to these is a model, $\frac{1}{32}$ the natural size, of the U. S. S. *Idaho*, as used as a hospital ship at Yokahama, Japan, devised by Surgeon A. L. Gihon of the navy; the middle deck being arranged towards the stern of the vessel with separate rooms for officers, the greater portion amidships being a large open ward with about thirty beds, water-closets and attendants' rooms being placed well forward. There is also a model of a cot for transporting wounded men, planned by Surgeon A. C. Gorgas, U.S.N., and so surrounded by canvas, rope handles, etc., that it may be readily lifted or lowered without inconvenience to the patient. This at present rests temporarily on an amputating table, which, by the folding of a leaf, may be converted into a writing table; a necessary combination, we doubt not, for economical purposes on shipboard, but one which would offer no tempting inducements for investment to a purchaser on *terra firma*.

Having recently passed through a practical experience of the mutual influence of medical gatherings and centennial expositions, we are disposed to urge our professional brethren, when the next centennial comes around, as come it must if we only give it a little time and wait for it with sufficient patience, not to attempt the combination again. The State Medical Society of Pennsylvania met here on May 31st; the American Medical Association June 6th. Before they came there were fabulous estimates of the numerical strength of each. The State Society would certainly bring five hundred to the city,—if for no other purpose, to visit the Centennial; the National Association, judging from letters and other documentary evidence in anticipation, would overflow all smaller halls of more perfect acoustic qualities, and pack Horticultral Hall to its utmost. When the eventful day of meeting came, the number of delegates and permanent members on the register in both conventions was but fifty per cent. of all previous calculations. The American Medical scarcely exceeded the aggregate of the 1872 meeting in Philadelphia; and of those who came, not half of the delegates were ever present at any one time. The Centennial Exposition proved too powerful a magnet. A procession of Knights Templars on Broad street, on the second and last day of its session, disturbed the equanimity of the State Society so grievously that the latter lost two hours while the delegates were gazing at the novel spectacle. Quite a number of the doctors paraded in the ranks, and for the time being found no attraction in any of the points of order or discussions that occupied the time of the Society. Not more than 125 or 150 were present at any moment at the State Society meeting, and yet on the third day, devoted to an excursion to the sea-shore, as if to show that they had come to the city for enjoyment, 325 delegates, and ladies accompanying them, participated in it. You can readily appreciate the demoralizing effect upon the American Medical Association when about four hundred—generally not more than three hundred—delegates found themselves in a hall which the committee of arrangements had wisely, as they thought, secured in anticipation of an incursion of fifteen hundred,—a hall which Proctor and Tyndall, and many other shining lights of the rostrum and the concert stage, had previously filled, with scarcely a murmur. The greater portion of the hall being empty, the audience restless and inattentive because they could not hear all that was said and done, many of the delegates departing Centennial-ward whenever a fair excuse in the shape of a lengthy paper was offered them. These and other similar drawbacks to complete success prevented the meeting of 1876 from being the perfectly happy consummation devoutly wished for by all those who had been so long working together to make it ever after a grateful Centennial souvenir.

R. J. D.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from June 11th to June 17th, 1876.

Jaquett, G. P., Asst. Surgeon. Granted leave of absence for four months. S. O. 115, A. G. O. June 9, 1876.

Byrne, C. B., Asst. Surgeon, Assigned to temporary duty at these Headquarters. S. O. 104, Department of Texas, June 8, 1876.

Semig, B. G., Asst. Surgeon. Granted leave of absence for one month, on Surgeon's certificate of disability, with permission to leave limits of the Department, and apply for an extension of two months. S. O. 70, Department of Arizona, June 2, 1876.

Medical Items and News.

Registration of Foreign Diplomas in England.—It has been decided by the Medical Council of England that foreign medical degrees are not registrable.

A New Medical School in Glasgow, Scotland.—A new medical school has been founded in Glasgow, Scotland, under the auspices of the Glasgow Royal Infirmary. Its first session will commence in November.

The English Vivisection Bill.—The restrictions provided in the bill are unanimously condemned by the Medical Council, but they, feeling that some legislation is called for, have determined to recommend the adoption of provisions which shall give free scope to the legitimate pursuit of biological study.

Midwives in Iceland.—A recent Danish law provides for the licensing and governmental support of midwives in Iceland. The salaries vary from fifteen to thirty dollars a year. These women must either have very little to do or else are very poorly paid.

A New Dental Hospital is about to be established in Dublin, after the plan of the London Dental Hospital.

The Illness of Dr. Gurdon Buck.—The many friends of this distinguished surgeon, who have been so anxious regarding his recovery from his severe illness, will be gratified to learn that his symptoms have taken a favorable turn, and that he is in a reasonably comfortable condition.

The National Educational Association will hold its sixteenth annual meeting in Baltimore, Md., on the 10th, 11th, and 12th days of July.

British Medical Service.—It appears that Dr. Rolleston, during the discussion on the New Warrant, before the Medical Council, took occasion to eulogize the medical service of the U. S. Army. In the course of his remarks he expressed the conviction that medical men were not "properly treated in any service except that of the United States, which had set an example in that respect to the whole civilized world." The London *Lancet*, in order to prove the contrary, quotes from our recent leading article on the comparison of the English with the American Service.

A New Appliance for Bloodless Operations.—Mr. H. L. Browne, surgeon to the West Bromwich Hospital, proposes in the *Lancet* for June 3d a very useful modification of Esmarch's bandage. A suitable rubber ring is rolled along the limb and over a plug placed on the main artery. This plug is provided with a groove upon its upper surface which receives the ring and keeps it from shifting. The rings are made of different sizes, as are also the plugs, although the latter are only used over the larger arteries. The apparatus may be used as an ordinary tourniquet, by stretching instead of rolling the ring over the limb and plug.

Dr. Joseph Carson has, on account of ill health, resigned his professorship of Materia Medica in the University of Pennsylvania. Dr. Horatio C. Wood will probably succeed him.

Rio Janeiro.—Yellow fever is epidemic at Rio Janeiro.

The Alcohol Question.—The municipal authorities of the large towns in Sweden, and first in Gottenberg, gave the whole liquor trade into the hands of certain societies composed only of the most respectable citizens. These societies buy wholesale the best—that is to say unadulterated—liquor, and are in every way responsible for its retail. No intoxicating liquors can be sold except by vendors whom they have chosen, and who follow regulations drawn up by the societies and pay the latter a certain sum annually for their privilege. The regulations require that no intoxicating liquors are to be sold any evening after ten o'clock, or between five o'clock Saturday evening and nine Sunday morning. Great care is also taken to have food and such unintoxicating beverages as coffee and tea placed before the customers wherever brandy is sold. All the profits accruing to the societies which have control of the liquor trade are devoted to public and charitable purposes and institutions.—*Philadelphia Medical Times.*

Georgia Medical Association.—The following officers were elected for the ensuing year: Dr. R. Battey, President; Drs. K. P. Moore and A. W. Calhoun, Vice-Presidents, and Dr. R. M. Smith, Censor.

New York Academy of Medicine.—At the final meeting for this season of the Academy, held at its building, 12 West Thirty-first street, Dr. Gouverneur M. Smith, when presenting a portrait of Dr. James Anderson, from Dr. James H. Anderson, in the course of his remarks spoke as follows in regard to the present condition of the Academy:

Mr. President: The duty has several times devolved upon me to read letters from donors to this Academy presenting portraits of its distinguished Fellows, and a similar pleasant duty is afforded me this evening. We have now owned and occupied this spacious and beautiful building a little more than a year. When the Committee of Ways and Means were busily engaged in raising funds for the purchase of a permanent home, the Committee felt assured that when the Academy possessed an appropriate edifice the medical profession of this city would be benefited thereby. Convenient rooms for the accumulation of portraits, of works of art, and of a library, and for meetings of this and of other associations, were thought to be essential in promoting medical science, medical unity, and the public welfare in this metropolis. This building has proved a pleasant nucleus for the profession. Hanging on our walls already are seven portraits of distinguished Fellows. The majority of these likenesses were painted expressly for presentation to this Society. To say nothing of the pecuniary value of these donations, what hallowed thoughts are awakened in our breasts on viewing the lineaments of our venerable and of our departed worthies.

Since our last meeting I have conferred with one of the most distinguished of our ex-presidents, and his portrait, it is hoped, will soon adorn our gallery. The family of one of our deceased members, a brilliant surgeon, will also furnish, it is hoped, an additional likeness. Your Committee will not relax its efforts until the portraits of all ex-presidents, and of other well-known and departed associates, are in the possession of the Society.

I am unauthorized to speak of the valuable contributions which have been made to our library, but at our meetings the accessions have been, from time to time, announced. Many of the volumes have been choice and rare. In this direction an accession of several thousands of dollars has been made to our property. Besides these portraits and volumes several select pieces of art have come into our possession since the occupancy of this building.

The Academy, however, is not as yet in a condition

to accomplish all its desires in the way of affording facilities to the profession, and as an individual member of the Committee of Ways and Means would venture to give a few thoughts relating to this matter. A debt of ten thousand dollars rests upon this building; our city taxes amount to over eight hundred dollars *per annum;* a volume of Transactions is being printed; a janitor has to be maintained; expenses for fuel and gas require a large outlay, and we need the services of an assistant librarian under a salary. Our dues are but ten dollars a year, and the desire is to decrease them as soon as possible. In a kindred society—the Bar Association—the dues, I am informed, are forty dollars annually. Now in order that the Academy can fully accomplish the liberal purposes for which it was designed, its members must make it an object of personal interest.

The Committee of Ways and Means have accomplished more already than the most sanguine predicted. Each Fellow, however, should regard himself *ex officio* a member of the Committee. Such of our number who have already subscribed to the building fund should endeavor to increase their subscriptions, and those who have as yet failed to do so, should without solicitation feel it a duty to contribute to the same object.

Our mortgage should be paid off at once, and steps be initiated to provide more liberally for the wants of the profession of the city than the Academy at present can afford.

The late Dr. John O. Stone, whose sudden death has just cast a gloom upon us, subscribed five hundred dollars towards the purchase of this building, and but a few days before his decease proposed to add another five hundred to his donation, provided a sum could be raised sufficient to liquidate our debt. Let us bear his dying thoughts in memory and derive counsel from them.

It is not speaking too enthusiastically to say that gifts of varied natures, amounting to thousands of dollars, will here find a place of deposit if the Academy places itself on a broader and firmer foundation. The Academy stands to-day in a better condition than it has ever before occupied, and, if true to its interests, its Fellows can now place it in the position which its founders, about thirty years ago, intended that it should occupy.

Death of Behier.—Another gap in the French Faculty of Medicine is occasioned by the death of Behier, who succumbed, after a long and painful illness, on the 8th instant, at the age of 63 years. To the very last, he was laboriously and incessantly engaged in professional pursuits. Among his published works are his *Traité de Pathologie Interne*, which, however, was never completed; and his *Leçons Cliniques*, in which are to be found special researches on erysipelas, stricture of the œsophagus, pneumonia, with special reference to its treatment by alcohol, maladies of puerperal women, etc. His name is also intimately associated with capillary thoracentesis, hypodermic injections, and transfusion of blood. He held the chair of Clinical Medicine at the Hôtel Dieu.

British Army Medical Service.—The new warrant for the Army Medical Service in Great Britain does not meet with much professional favor.

Office Hours.—The fashionable office hours in New York are between nine and twelve in the morning. This arrangement gives an opportunity for seeing urgent cases early in the day, as well as an early morning airing.

Swiss Universities.—In the three Swiss Universities of Zurich, Berne, and Basle, there were, during the Winter Semestre 1875—1876, according to the official registers, 831 students, who were divided as follows: Zurich, 330; Berne (including the veterinary school), 299; Basle, 202. Out of this number there were 175 foreigners, viz.: 54 Germans, 52 Russians, 24 Austrians, 15 Americans, 12 Greeks and Turks, 7 Englishmen, 4 Frenchmen, 2 Italians, 1 Belgian, 1 Spaniard, 1 Hollander, and 1 Asiatic. In Zurich and Berne there were 63 female students, only 2 of whom were Swiss. of the rest 39 were Russians, 8 Americans, 5 Austrians, 4 Germans, 3 Serbians, one was French, and one English. The educational staffs of the three Universities numbered 101 regular professors, 37 assistants, and 61 instructors (agrégés). There was consequently one teacher for every four students. According to the *Augsburg Gazette*, there is in the University of Berlin only one teacher for every ten students, in the University of Leipsic one for seventeen, and in that of Munich, one for eleven. The *Journal Officiel* from which these numbers are taken, does not give the proportions which exist between the teachers and the students in France. According to the *Progrès Médical*, this failure to give the figures for France, is evidence that they would be but little to the credit of the country.

The Murder of Dr. George Cook, of Brigham Hall Insane Asylum, N. Y.—Dr. George Cook, the Medical Superintendent of Brigham Hall, Canandaigua, was fatally stabbed in the neck by an insane patient on the morning of June 12th, dying the same evening. The patient was a farmer by the name of Benson, who had only been recently admitted, and was not considered dangerous. He seemed to have been impressed with the idea that people were trying to poison him, and that Dr. Cook was endeavoring to administer the poison. Yesterday morning the Doctor, in making his usual rounds among his patients, met Benson in his room or in one of the halls. Benson immediately struck the doctor in the face and neck with a knife. Help was soon at hand and physicians summoned, and strong hopes were entertained for a time that the wounds would not prove fatal. All that medical and surgical skill could devise was brought to bear in the case, but failed, and the Doctor died about five P.M. His age was about fifty years. Benson had evidently prepared the knife for the attack on the Doctor, as it was found to have been recently sharpened, and he had wound cloth or paper around the handle, so that he could retain a firm hold of the instrument of death.

Influence of Vaccination.—In the German army, vaccination and revaccination are obligatory. According to statistics collected by the German authorities, the German army, which numbered a million men during the war with France, lost only 286 men by variola, while the French army lost nearly 26,000 by that disease.

Duval (Vincent), laureate of the Institut in 1839, Director of the Orthopedic treatment in the civil hospitals of Paris, died at Neuilly on the 29th of April, 1876, at the age of 80 years. He founded the Orthopedic establishment of Chaillot, was the first in France to perform tenotomy of the tendo Achilles in the treatment of club-foot, and one of the first to practice subcutaneous tenotomy. He published several works on Orthopedics, on the use of the mineral waters of Plombières, etc., etc. Dr. Joulin described him as "*grand homme, grandes moustaches, et grand couleur.*" One of his sons is founder and director of the hydrotherapeutic establishment of the rue du Dome.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, July 1, 1876.

THE USE OF PROPRIETARY MEDICINES.

Considering the great opportunity afforded the late President of the American Medical Association for saying a good word for the profession, we are the more surprised at the manner in which he treated the subject of proprietary medicines in his recent address. No one doubts that physicians have long been prescribing patented medicinal preparations, but such a reprehensible practice cannot be viewed as an argument to prove that the part of the Code of Ethics which forbids it should be modified or abolished. The fault of wrong-doing rests not with the law which is intended to prevent it, but with the individual transgressing. As the case now stands, the profession has been humiliated before the world by the virtual admission that not infrequently it is compelled to call in the aid of quackery to cure disease. If this be a fact, how can we reconcile our pretentious advocacy of the claims of scientific medicine? The use of secret remedies is such a disgraceful reflection upon the resources of our art, that the best we can say for it is that the more the practice is hidden in the humiliation of our own incompetency the better for the profession at large. But what have we to say of the wide-spread publication of an opinion from a leader in the profession, and a president of the representative Medical Association of America, that quack remedies are so useful in the treatment of disease that we cannot do without them, and that in view of making principle consistent with practice, we should alter our Code?

We cannot believe that the profession will hold itself responsible for this error of judgment on the part of the President of the Association. In the name of that profession we cannot too strongly condemn the principle upon which the argument is founded, and cannot too radically express our mortification of the mistaken policy which gave it such untimely utterance.

As a question of principle we must take a firm stand against every innovation of quackery, notwithstanding it may be backed by the very priests at our altars. The provisions of the Code in regard to the use of patent nostrums are explicit enough to suit the good intentions of every practitioner, high or low; and as far as the principles are concerned are beyond criticism. If science cannot compete with quackery, humbug, and ignorant empiricism in finding remedies for disease, it is time that we enlarged our laboratories, improved our methods of analysis, and studied our materia medicas. What kind of a spectacle do we present to the world in regard to the use of proprietary medicines? We claim, as leaders in professional thought, to be masters of the science of medicine; as well qualified practitioners, to be capable of making every possible application of the resources of that science for the good of our patients; and yet we acknowledge that the veriest quack can blindly stumble upon a remedy which we are glad to use, although ignorant of its composition. We cannot believe that the profession is willing to stultify itself before the public by any such admission. In that view we wish to see the Code stand where it is. The principle upon which it is founded cannot be improved, and we should jealously guard against any infringement of its provisions, not only by the ordinary practitioner, but by the President of the Association himself.

It is our duty and privilege to use anything and everything in the shape of medication which may be of service to our patients. We should fulfil these conditions without recourse to proprietary medicines. Even granting that some quack may throw a valuable remedy in our way, we have the facilities for ascertaining its quality and composition; but failing to do so, we should not, as scientific men, use it at all; in other words, we have no right to prescribe any remedy the composition of which we are ignorant.

It is often said by physicians in regard to proprietary medicines: "I know that this compound is a good one, and I use it." This is well enough as far as it goes, but unless the prescriber takes pains to ascertain upon what the good effects of such a remedy depend, he ignores all the claims of scientific therapeutics and sinks into the hopeless imbecility of aimless empiricism. While we are willing to admit that this evil of striking at disease in the dark is secretly winked at by many physicians, it is nevertheless radically wrong, and should, far from being excused, be unqualifiedly condemned as a disgraceful method of dodging the sacred obligations which we owe to our patients, and of sacrificing the best interests of legitimate medicine.

As a rebuke to the sentiments of the President on this question, we notice a coincidence almost providential in its significance, in the rejection of one of the papers read before one of the sections of the Association because its author advocated the claims of a secret remedy. A similar action for a similar reason was taken upon a paper read before the State Medical Society at its recent meeting. This is as it should be,

and the unanimous vote of the members is a pretty clear indication of the drift of professional opinion. The proper interpretation of the latter will prove to the President of the Association that the profession would much rather raise the standard of professional morals to the high level of the requirements of the Code, than lower that level to suit the convenient requirements of those who are proper subjects for discipline.

THE MEDICAL COLLEGE CONVENTION.

The holding of a Convention of Medical Colleges proves the existence of a laudable intention on the part of practical educators of discussing some of the possibilities of reform in medical education. As will be seen from the account of the proceedings in another column, many important suggestions were made, and concerning many abuses of the college system a definite opinion was expressed. Notably in this connection, the short-term system, so ably advocated by Dr. Gaillard, received a well-deserved rebuke. From the tenor of resolutions presented by Prof. Curtis, it will be seen that we are not the only ones who believe that shortening the term of college study, even under the most favorable circumstances, is detrimental to the interests of the student, and should be openly criticised. The beneficiary system, which is carried to such perfection in the school of double diplomas, is also unqualifiedly condemned. The recommendation of a system of graded study is another of the indications that the Convention is keenly alive to the necessity of reforms so long urged by the profession.

THE ASSOCIATION OF AMERICAN SUPERINTENDENTS OF ASYLUMS FOR THE INSANE.

The meeting of the Association of American Superintendents of the Insane, recently held in Philadelphia, proved to be so interesting that we have given a full report of it.

The importance of a proper care and treatment of the insane need not be urged upon the general practitioner, neither is it necessary to state that the opinions of the members on these subjects are of the highest value. Each of the gentlemen composing this Association has charge of an asylum for lunatics, and is an alienist of high authority and extensive experience.

We are pleased to see that the Association was not backward in the expression of its opinion concerning the disgracefully crowded condition of the Philadelphia Almshouse for the Insane, and it is to be hoped that some good will come of it. It is unnecessary to allude in detail to the scientific work done by the Association, as the report will, we trust, be sufficient to vindicate our judgment as to its value.

THE MEDICAL SOCIETY OF THE STATE OF NEW YORK.

The Medical Society of the State of New York discussed during its meeting many questions connected with scientific and legislative medicine. The addresses of the President were exceedingly interesting and appropriate, and well sustained his reputation for scholarly attainments. The papers were on the whole good, and claimed the attention of the members. The subject of permanent membership was very thoroughly ventilated, and the society finally adopted the report of the committee. The advisability of revising the pharmacopœia was well entertained, and the suggestion that the matter lie over for another year was well considered. The resolution advising the establishment of independent examining boards for the colleges of the State met with the respectful reception which the importance of the movement demanded, but for lack of the necessary time for its discussion action was deferred until next year.

The publication of the Transactions has proved to be, pecuniarily speaking, a rather unprofitable undertaking. The fact that nine hundred volumes, half the original edition, are left upon the Society unsold, proves either that there is no great demand for the volume, or that the Committee of Publication and publishers failed to avail themselves of the ordinary facilities for advertising. The election of Dr. Squibb, of Brooklyn, as President for the ensuing year was eminently satisfactory to all.

Reports of Societies.

MEDICAL SOCIETY OF THE STATE OF NEW YORK.

SEVENTIETH ANNUAL MEETING.

JUNE 20.—FIRST DAY.—MORNING SESSION.

The Society met, pursuant to statute, in the Assembly Chamber, Albany, at 11 o'clock A.M., June 20th, 1876. The President, DR. THOMAS F. ROCHESTER, of Buffalo, called the meeting to order, and prayer was offered by Rev. Dr. A. J. Upson, of Albany. The President then delivered his

INAUGURAL ADDRESS,

in which he first made reference to the general sanitary condition of the State, and noticed the close relations which had existed between fluctuations in the prevalence of diseases and the fluctuations in temperature and barometric pressure. To the end of bringing about a systematic study of such relation, Dr. Rochester encouraged the association of health boards with the weather bureau.

The Doctor then passed to the consideration of certain

THERAPEUTICAL MEASURES

resorted to in the antipyretic treatment of disease. He regarded it as a subject demanding the greatest consideration. The views which at present were largely adopted had been derived, for the most part, from Ziemssen's *Cyclopædia of Medicine*, published in so attractive a form by the widely-known medical book publishers, Wm. Wood & Co., of New York. The measures referred to were water, quinine, and arterial sedatives; and, said Dr. Rochester, "is it not well to be cau-

tious about embracing too fully this new theory?" He was inclined to think that perhaps the enthusiasm of the Germans had biassed their reason; that they might have possibly erred in a direction opposite to homœopathy, and had recommended the use of too large doses. There might be danger that the valuable remedy, quinine, would be brought into disrepute by an indiscriminate use. *Salicylic acid* was referred to, and the doctor had been led to regard its action in rheumatism as similar to that of propylamin. With regard to all remedial agents, Dr. Rochester believed that the needed lesson of the present day was *caution*; caution with respect not exactly to the quantity, but to the *bulk* administered. If the patient required medicine, the question should be, how little did he require, and not how much would he tolerate? Nothing special had occurred in surgery to chronicle.

PRELIMINARY EDUCATION OF MEDICAL STUDENTS.

The President recommended upon this question that the requirements of the State Society be enforced. The course of instruction instituted at Harvard College was sustained, as leaving no loop-hole between the schools and the student, and at the same time it did not do away with the advantage of having a private preceptor.

SCHOOL HYGIENE.

Dr. Rochester next turned his attention to the above subject, and remarked that education was not, in all instances, the unmistakable blessing which it seemed to be, for it became necessary to acquire it at too great risks. His conclusions upon this point were, that no child under ten should be sent to a public school, and that every school district should have a competent and well-paid medical director, who should devote himself thoroughly and conscientiously to the many hygienic duties of the position.

It would not involve an increased expense; on the contrary, it would be to the community a most economical procedure. The Society, as representing the profession of the State, should take some action which would inaugurate and perpetuate a reform in this respect.

Dr. Rochester then referred to the members and delegates who had died since the last annual meeting. They were:

Dr. Coventry, of Utica; Dr. McNutt, of Warrensburgh; Dr. J. H. Armsby, of Albany; Dr. Peter McNaughton, of Albany; Dr. J. R. Van Kleek, of New York; Dr. Edward Delafield, of New York; Dr. Foster Swift, of New York; Dr. Ernst Krackowizer, of New York; Dr. Hubbard, of Lansingburgh; Dr. Wilkie, of Auburn; Dr. F. W. Root, of Hamilton, N. Y.; Dr. J. V. P. Quackenbush, of Albany; Dr. George Cook, of Canandaigua.

The President recommended an additional number of Vice-Presidents. He also recommended that an alphabetical list of permanent members appear in the volume of Transactions. He further stated that the bill requiring bail for costs in suits for malpractice had been found, as he had been informed, to be impracticable.

INTERNATIONAL MEDICAL CONGRESS.

The President then designated the following gentlemen to represent the State Medical Society at the *International Medical Congress* to be held in Philadelphia, on Monday, September 4th: Drs. Frank H. Hamilton, Chairman; Alonzo Clark, B. Fordyce Barker, C. R. Agnew, Ellsworth Eliot, and Austin Flint, Jr., of New York City; J. C. Hutchinson, E. R. Squibb, and Alex. Hutchins, of Brooklyn; Wm. H. Bailey, E. R. Hun, and Chas. H. Porter, of Albany; James P. White, Julius F. Miner, of Buffalo; Henry W. Dean, E. M. Moore, of Rochester; L. L. Tefft, H. D. Didama, Syracuse; John P. Gray, Utica; Edward H. Parker, Poughkeepsie; George Burr, Binghamton; Frederick Hyde, Cortland; S. O. Vanderpoel, Quarantine; G. A. Dayton, Mexico; Wm. C. Wey, Elmira; B. F. Sherman, Ogdensburg; Geo. J. Fisher, Sing Sing; Harvey Jewett, Canandaigua; J. Foster Jenkins, Yonkers; A. M. Vedder, Schenectady; Wm. Vosburg, Lyons; John D. Button, Auburn; Thomas M. Flandreau, Rome.

In conclusion, Dr. Rochester recommended that the delegates suggest action for the purpose of establishing a uniform system of weights, measures, and symbols throughout the world.

At the close of the President's address a telegram was read from Dr. Ellsworth Eliot, Vice-President, announcing his necessary detention in New York, on account of the sickness of Commodore Vanderbilt, whom he was attending. For that reason he also tendered his resignation; but upon motion of Dr. White, of Buffalo, the resignation was laid upon the table.

Dr. White then moved that Drs. J. C. Hutchinson and E. R. Squibb, of Brooklyn, and Dr. Chase, of Westfield, be appointed Committee upon the President's address. Carried.

The President then announced the following committees:

On Business.—Drs. Wm. C. Wey, J. Foster Jenkins, and M. H. Burton.

On Credentials.—Drs. T. D. Strong, Thompson Burton, Alex. Hutchins.

On Reception and Arrangements.—Drs. W. H. Bailey, E. H. Parker, E. R. Hun.

On Ethics.—Drs. E. M. Moore, Alonzo Churchill, J. W. S. Gouley.

On Nominations.—1st District, Dr. Henry D. Noyes, New York; 2d, Dr. George J. Fisher, Chairman, Sing Sing; 3d, Dr. R. B. Bontecou, Troy; 4th, Dr. Francis Burdick, Johnstown; 5th, Dr. Judson B. Andrews, Utica; 6th, Dr. J. B. Orton, Binghamton; 7th, Dr. Chas. G. Pomeroy, Newark; 8th, Dr. J. F. Miner, Buffalo.

On motion, a recess was taken for ten minutes to perfect the order of business. On reconvening, Dr. Wm. H. Bailey introduced Dr. E. D. Silvers, from the New Jersey State Medical Society, and Dr. A. P. Grinnell, of the Vermont State Medical Society, and they were invited to participate in the deliberations of the Society.

Dr. Bailey reported the names of the following gentlemen as invited members: Drs. L. D. Buckley, S. B. Wood, W. G. Tucker, A. Vanderveer, G. H. Armsby, M. R. C. Peck, F. C. Curtis, H. S. Case, D. H. Cook, T. M. Trego, and E. Beach.

The first paper was read by Dr. George Bayles, of New York, and entitled

CLINICAL STUDY OF DIPHTHERIA IN 1875.

Dr. Bayles' observations had been made chiefly upon dispensary patients, and he had introduced a test to determine what the nature of the disease was before the membranous exudation appeared. The test consisted in abrading the mucous membrane with a knife, when, if the case was one of diphtheria, the abrasion was soon covered by a diphtheritic deposit. All his cases recovered, and in none did paralysis follow. The constitutional symptoms began to yield in every instance about the eighth day. The object of the doctor's paper was to prove a doctrine precisely the reverse of that advocated by Dr. Billington, of New York, in a paper read before the Academy of Medicine,

and published in a former number of THE MEDICAL RECORD. He regarded diphtheria as probably an autochthonous disease, and not only that, but homo-autocthonous. With regard to treatment, his first intention was to strike a vigorous blow with the view of aborting the disease, and the agent he employed for that purpose was calomel, in not less than ten nor more than thirty grains given in a single dose. He supplemented the calomel with quinine and Dover's powder, with the view of producing diaphoresis without producing exhaustion. With the view of neutralizing and eliminating the poison, he used the elixir iodo-bromo-chloride of calcium in drachm doses, and also used the same remedy in the form of spray or gargle, whether patches were present in the throat or not. Nothing more was employed in the way of local treatment. The temperature and ventilation of the room, and proper care of the patients, were not neglected, and more or less of stimulants were employed.

The paper being open for discussion, DR. E. R. SQUIBB, of Brooklyn, remarked that he raised an objection to the paper appearing in the Transactions of the Society, upon the ground that in it a secret remedy was recommended. The fact that a proprietary medicine was introduced was sufficient, in his judgment, to prevent the publication of the paper as receiving the endorsement of the Society. There was much in the paper doubtless that was beyond his criticism, and it was perfectly proper that it should be published in the journals. It was only with reference to the point alluded to that the adverse criticism was made.

DR. BACON, of Oswego, criticised the paper because the author recommended the administration of *ten* grains of calomel to a child five months old, and he also believed that three grains of Dover's powder, combined with one grain of quinine, as recommended for a child of the same age, was a pretty solid prescription.

Upon motion made by DR. SQUIBB, the Society declared that the paper by Dr. Bayles was not a proper one to appear in the volume of Transactions.

On motion of DR. WM. H. BAILEY, the Treasurer of the Society was made trustee of the Merrit H. Cash prize fund, *vice* Dr. J. H. Armsby, deceased.

The Society then adjourned to three o'clock.

FIRST DAY—AFTERNOON SESSION.

The Society was called to order at three P.M. by the President, and the first paper was read by DR. ROBERT NEWMAN, of New York,

UPON THE BEST ELEMENTS FOR A GALVANIC BATTERY.

The Doctor introduced to the Society a new element, consisting of zinc and gold upon lead. It was maintained that batteries containing elements made in that manner possessed twenty-five per cent. more force than either the Dawson, the Byrne, or the Bunsen battery. The doctor did not exhibit a battery, but presented four pairs of elements, simply for the purpose of showing the initial force of each. A battery constructed upon his plan would cost thirty-five dollars.

The second paper was read by DR. EUGENE BEACH, of Gloversville, and consisted in the history of a case of

RETENTION OF URINE, WITH HYPERTROPHY OF THE PROSTATE GLAND, TREATED BY ASPIRATION—THE AUTOPSY AND MICROSCOPICAL EXAMINATION OF THE KIDNEYS.

The man was aspirated twenty times in eight days. The prostate was enormously enlarged. Infarctions were found in the left kidney, and it was the opinion of Dr. Vandervecr, of Albany, who made the post-mortem, that the hemorrhage from the kidneys was sufficient to account for blood in the bladder found after death, and which obstructed the flow of urine when the catheter was introduced. Right kidney congested.

DR. BAILEY introduced Dr. Calvin C. Halsey, delegate from the Pennsylvania State Medical Society, who responded with appropriate remarks.

DR. WHITE, of Buffalo, presented the report of the Committee on Prize Essays.

Two essays had been presented for the Merrit H. Cash prize, but the prize had been awarded to the one bearing the following motto: "Physiology has become a science by well-conducted experiments that have illustrated facts. Can Therapeutics claim to be a Science, while so many of its votaries are content with assertions without experimental facts to support them?"

The report of the Committee was accepted by the Society, and the Chairman directed to open the sealed envelope upon which was written the same motto, when the name of DR. SAMUEL R. PERCY, of New York, was found.

DR. WHITE then proceeded to report his twelfth case of

INVERSION OF THE UTERUS SUCCESSFULLY TREATED BY MEANS OF THE "EGG-BEATER REPOSITOR."

Before giving the history of the case, Dr. White reiterated the doctrine he had so long held, and so often published upon the subject.

The Doctor also exhibited several cases of

FŒTATION BY INCLUSION

which had been passed from the urethra of an unmarried woman, and regarded them as probably the result of extra-uterine pregnancy. It might have been a case of fœtation by inclusion.

DR. GOULEY, of New York, asked Dr. White whether any cranial bones had been passed?

DR. WHITE replied that no cranial bones had been found, but that the pelvic bones, clavicle, thigh bones, lower maxillary, and several others had passed.

DR. GOULEY remarked that he had seen portions of the maxillary bones in a cyst of the testicle of a boy under five years of age, which was evidently a case of fœtation by inclusion. The passage of the cranial bones would settle the question whether it was a regularly formed fœtus or otherwise.

The next paper was read by DR. L. DUNCAN BULKLEY, of New York,

ON THE TREATMENT OF PURPURA.

The interest in Dr. Bulkley's paper centred upon the use of ergot hypodermically in the treatment of that affection. He preferred the fluid extract to ergotine. The injections were introduced by preference about the pectoral muscles or sides of the chest. Large doses were required, and ℥ x. or xv. or even xx. or xxx. might be repeated every hour and a half. The remedy might also be given by the mouth, and he related a case in which he used ʒ ij. of the fl. ext. within ten days, administered in half-drachm doses. Dr. Bulkley also made some remarks upon hemorrhagic small-pox, chiefly relating to the differential diagnosis between it and measles.

The President called DR. KENDALL, of Onondago Co., to the Chair.

The paper being open for discussion, DR. SQUIBB remarked that he wished to say a single word of caution with reference to the size of the dose of the fl. ext. of ergot. Dr. Bulkley had recommended that ounce doses

of the fl. ext. might be administered without harm, but that must be exceptional. He should be very sorry to have the paper go out from this society without some check as regards such a dose as that. He believed that ergot, like very many other drugs, was liable to tolerance, but to make the broad statement that in ordinary cases the fl. ext. could be administered in ounce doses had a large element of danger in it. Papers presented there were not like papers presented for publication in the Journals. They stood then upon the endorsement of the Society; and if they went out in the Transactions, they went out with its endorsement.

Dr. Castle, of New York, directed attention to the fact that the injection in Dr. Bulkley's cases had been made in the gluteal and posterior scapular regions; and he was of the opinion that a much more favorable locality was the anterior wall of the abdomen, on account of the less liability to wound important nerves and blood-vessels, and in case abscess should be formed, it would not give the patient so much inconvenience as if situated in either of the localities mentioned.

Dr. Bulkley remarked, with regard to the size of the dose referred to by Dr. Squibb, that he recommended from ℥ x. to xv of the fl. ext., and only exceptionally a half drachm. The statement with regard to half and whole ounce doses, was according to Dr. H. C. Wood, of Philadelphia; but Dr. Bulkley did not embody it in his paper, did not regard it as his own statement, and should be sorry to have it impair the value of the paper.

With regard to the criticism of Dr. Castle, Dr. Bulkley remarked, he recommended that the injection should be introduced somewhere about the soft parts of the pectoral muscles or sides of the body. It was in a case which Dr. Hanks had treated, and to which Dr. B. had referred, that the injections were made in the gluteal region. Cleanliness of the syringe, slowness of administration, and depth of insertion, were regarded as points of importance, if the best effects would be realized from the remedy, and abscesses avoided. Dr. B. regarded abscesses as of infrequent occurrence if the injections were properly given.

Dr. Cartwright, of Delaware Co., asked if ergot was so valuable in the treatment of various hemorrhages and spinal congestion, why it would not be serviceable in the treatment of congestion of the brain, especially in congestive apoplexy?

Dr. Squibb regarded Dr. Bulkley's experience with reference to abscesses following the use of ergot hypodermically as unusually favorable, and thought that there were gentlemen present who had had a very different experience. He did not believe that Dr. Bulkley meant to incorrectly represent the result of using the remedy in that manner when he spoke of the general harmlessness of the injections; but his experience, and he believed that of others, did not justify such conclusion.

Dr. Wey, of Elmira, remarked that formerly abscess almost invariably followed his use of ergot hypodermically; but latterly, since he had used Dr. Squibb's aqueous solution, and used it only of such strength that *one minim represented one grain*, no more, he had not seen a single abscess produced, and the effect was just as decided.

Dr. Squibb remarked that the aqueous extract was much less irritating than the ordinary fluid extract, and further remarked that with regard to effect produced, it was best to gradually increase the dose until uterine colic was produced, and then fall a little back of that point, when the drug could be continued.

Dr. Stoddard, of Rochester, remarked that he had seen one drachm of the fluid extract introduced into the cavity of the uterus by Dr. Dean, of that city, and the physiological action of the drug produced within half an hour in most cases, and the effect was no more severe than when ℥ xv. or xx. were used hypodermically.

He had not seen any ill effect follow the introduction of the drug into the substance of the uterus itself, and had seen employed for that purpose Squibb's solid extract in the strength of one grain to ten minims of water.

Dr. Wey remarked that the largest dose of ergot he had employed was that in which one drop represented four grains of the powdered ergot; and the barrel of an ordinary hypodermic syringe had been filled and thrown into the connective tissue day after day without unpleasant symptoms other than the formation of abscess.

Dr. Squier remarked, with reference to poisoning by ergot, that there was no evidence of the existence of such symptoms as were detailed in the older text-books. He had repeatedly known of drachm doses being administered three or four times a day without rendering patients uncomfortable in any such sense as being toxic.

The next paper was read by Dr. James Chapman, of Medina, and consisted of the report of two cases of

TUMOR OF THE BREAST OF AN UNCERTAIN CHARACTER.

(We regret to say no microscopical examination was reported.)

Dr. E. H. Parker, of Poughkeepsie, exhibited a substitute for the hypodermic syringe, which consisted of a needle attached to a piece of glass tubing or barrel in the ordinary manner, and a rubber bulb at the other end to be worked with the thumb and finger.

Drs. Sayre, Sherman, Jenkins, and Bulkley were hardly able to coincide with Dr. Parker concerning the utility of the instrument.

After some discussion with reference to the question of discussing papers immediately after they were read, the subject was laid upon the table, and the Society adjourned to meet at nine A.M., June 21st.

WEDNESDAY, JUNE 21—SECOND DAY.—MORNING SESSION.

The Society was called to order at nine A.M. by the President; and prayer was offered by Rev. Bishop Doane.

The President announced that Dr. Orton, from the Sixth, and Dr. Miner, from the Eighth District, upon the Committee on Nominations, were not present, and substituted the names of Dr. Wm. Fitch, of Dryden, to represent the Sixth, and Dr. L. B. Cotes, of Batavia, to represent the Eighth District.

The minutes of the previous day were read, after which Dr. Squibb brought up the matter of conferring the Merritt H. Cash prize, and showed that the requirements of the Society had not been complied with, hence the prize had been improperly awarded by the committee. The author had not written upon the subject designated.

The President regarded the correction as well made, but further consideration of the subject was postponed until the afternoon session.

Dr. Wm. H. Bailey, of the Committee on Invitation, presented the following names: Drs. Henry Nachtel, of Paris, France; A. L. Lowell, Geo. P. Salmon, Isaac D. Meacham, W. A. Talmadge, T. Ham-

mond, Lewis Balch, J. B. Boyd, Jr., Geo. T. Stevens, I. De Zouche, E. Van Slyke, J. B. Stonehouse, C. S. Merrill, G. S. Ullman, W. H. Murray, John Thompson, J. C. Hannan, W. Hailes, E. B. Tefft, H. J. Fellows, W. W. McGregor, O. D. Ball, Hammond, of Dutchess Co., A. F. Sheldon, and J. D. Buchner.

The Treasurer's report was read and accepted, and referred to a Committee consisting of Drs. N. C. Husted, T. Dimond, and J. L. Banks.

COMMITTEE ON PUBLICATION.

Dr. A. E. M. Purdy, of New York, read the report, which was accepted.

The chief items were as follows: The number of Transactions for 1876 shall be 1,500; the committee shall hold the copyright in the name of the Society, and shall invite proposals for the printing, awarding the work to the lowest bidder; the style shall be the same as 1875, and the expense shall be defrayed by contributions from the county societies, they to receive a number of copies proportionate to the amount contributed; copies shall be sent to delegates from other States present at this meeting, to each medical library, and to other public libraries known to have a medical department; papers not placed complete in the hands of the committee within thirty days after the close of the session shall be excluded from the volume; and it shall be supplied to members and county societies at a price fifteen per cent. greater than their cost; the publication price shall be thirty per cent. greater than cost.

The committee also made a financial statement, showing that there was due for deficiency $413.60.

Dr. Parker, of Poughkeepsie, moved the adoption of the report, and offered the following amendments:

First, That no portrait be hereafter introduced into the Transactions without the vote of the Society. Carried.

Second, That lists of members of the various county medical societies be introduced annually into the volume of the Transactions.

Dr. Parker urged the amendent for the reason that it would be a great convenience to have a volume containing such list, without being obliged to buy the *The New York Medical Register*. The amendment was adopted.

On motion of Dr. Squibb, the Treasurer was added to the Committee on Publication, and the report as a whole was then adopted.

In the midst of the discussion upon the report Dr. Hiram Corliss, of Greenwich, Washington County, the oldest member of the Society, entered the chamber, and was received with cheers, the members rising.

Dr. Hutchison, from the Committee on President's Address, submitted the following report: In regard to the suggestion that the number of Vice-Presidents be increased, the committee recommended that no change be made. The suggestion to arrange the list of permanent members in alphabetical order was adopted. The committee recommended, in regard to the Merrit H. Cash prize fund, that the Treasurer of the Society be directed to pay to the author of the last prize essay from the funds of the Society the sum of $50, so as to place this prize essay on an equality with those which have preceded it, and that hereafter the prize offered be $100, only to be offered as often as the accumulated interest amounts to such sum. The committee also recommended that the name of President Rochester be placed at the head of the delegation to attend the International Medical Congress, and that his appointment of delegates be confirmed

The President took the floor, and objected to the last clause of the report, but his objection proved unavailing, and the report of the committee was adopted by a unanimous vote.

Dr. J. P. White moved that in case of a vacancy occurring in the delegation, the President of the Society be authorized to fill it. Carried.

Dr. O. White, of New York, from the Committee on By-Laws, reported a resolution that the Secretary of the New York County Society, and other societies who have revised their by-laws, be requested to send copies thereof to the committee of the State Society. The report and resolution were adopted.

Dr. Wm. H. Bailey announced an invitation, extended by President Rochester to the members and delegates and invited guests, to attend a reception at the Delavan House in the evening immediately after the delivery of the anniversary address. The invitation was accepted.

The next business in order was the reading of a paper on

LITHOTOMY AND LITHOTRITY,

with an analysis of thirty-five cases, by Dr. J. W. Gouley, of New York. It will appear in our next issue.

The paper was discussed by Drs. Corliss, Hamilton, Hutchinson, Vanderveer, Squibb, and Sherman.

Dr. A. N. Bell, of Brooklyn, then read a report from the

COMMITTEE ON HYGIENE.

It embraced reports from Saugerties, Yonkers, Rochester, Elmira, Ogdensburgh, and other parts of the State, upon defective drainage, water supply, etc., as giving rise apparently to the prevalence of zymotic diseases.

Dr. E. R. Squibb made his report as delegate to the American Medical Association, in which was embraced a lengthy consideration of the question of revision of the U. S. Pharmacopœia. Upon motion, the report was received, and the Publication Committee instructed to incorporate it in the Transactions. The resolutions introduced by Dr. Squibb can be found on page 395 of The Record for June 17th, 1876.

Dr. Dimond, of Auburn, then read a paper upon

EXTENSIVE DISORGANIZATION OF THE BRAIN WITHOUT CORRESPONDING LOSS OF FUNCTION.

Almost the entire brain had become a purulent mass, and yet there was no apparent loss of function, except of sight, which it was thought was explained by the pressure made by pus found upon the optic commissure. The Society then adjourned to meet at three P.M.

SECOND DAY—AFTERNOON SESSION.

The following papers, by title, were referred to the Committee on Publication:

Biographical Sketch of Prof. J. H. Armsby, M.D., Albany, by Willis G. Tucker, of Albany; Biographical Sketch of the late George H. Hubbard, M.D., of Lansingburgh, by Henry B. Whiton, M.D., of Troy; History of the Livingston County Medical Society, by Walter E. Lauderdale, M.D., of Geneseo; A Case of Fungus Cerebri, by Nelson Fanning, M.D., of Catskill; An Address upon Malpractice, read at the annual meeting of the Washington County Medical Society, by A. W. Tupper, M.D., of Groversville, President; Early Medicine in New York Province, by R. M. Wyckoff, M.D., of Brooklyn; Biographical Memoir of John Ferguson, M.D., of Albany, by Wm. M. McGregor, M.D., of Albany; A Case of Vegetating

Epithelioma of the Cervix Uteri, with Subinvolution of the Uterus and Pelvic Cellulitis, with Remarks upon its Etiology and Symptomatology, by C. E. Fraser, M.D., of Rome, read before the Oneida County Medical Society, June 1st, 1875; Biographical Sketch of the late Drs. Coventry and Bissell, of Utica, by Daniel J. Thomas, M.D., of Utica.

Dr. George J. Fisher, of Sing Sing, read the following:—

REPORT OF COMMITTEE ON PERMANENT MEMBERSHIP.

I. No one shall be, or shall be declared to be, eligible for election as permanent member who shall not have attended three annual meetings of this Society as a delegate, which meetings shall not be restricted to any one term of service of the delegates.

II. A division, on the basis of the above conditions, of the existing list (*vide* Trans., 1875, p. 465) of those who have heretofore been declared to be "eligible for election as permanent members," shall be made. There shall be two parts, which shall contain the names of

(*a*) Those who have attended three annual meetings as delegate; and

(*b*) Those who have not attended three annual meetings as delegates.

In all future elections of permanent members the names of those in Part II. shall be first considered.

It is recommended, if it be competent to do so, that the eligibility of those in Part II. be suspended until they shall have attended a total of three annual meetings, as above required, upon doing which their names shall be put upon Part II. without further action by the Society.

III. Hereafter permanent members may be elected annually from each of the (8) eight Senatorial districts of 1836, in the proportion of one permanent member to every eight delegates from the County Societies to which the district may be entitled, and one for every additional fraction of one-half or more of this number. At the time of their election, permanent members shall be residents of the districts which are credited with them, and shall be in good standing as active members of their County Societies.

IV. Each permanent member shall pay to the Treasurer of this Society an annual assessment of two dollars.

V. Each permanent member, who shall have paid his annual dues, shall have a copy of the Transactions for the year for which he shall have paid, sent to him by the Committee of Publication.

VI. Any permanent member, who shall fail to pay to the Treasurer his annual dues for three successive years, shall forfeit his permanent membership, and his name shall be dropped from the rolls of this Society. In this case, the permanent membership can be restored by subsequent payment of all arrearages to date.

VII. Any permanent member who shall be reported by the Medical Society of his county as being no longer in good professional standing or in active fellowship therewith, shall lose his membership, and his name shall be dropped by the Society.

VIII. Any permanent member who may remove from this State, shall lose his connection with this Society.

IX. Permanent members shall not act as delegates from County Medical Societies.

George J. Fisher.
Wm. C. Wey.
J. S. Prout.

The report was accepted, but its adoption gave rise to discussion; when it was made the special order for the morning session, June 22.

ROTARY LATERAL CURVATURE OF THE SPINE.

Dr. L. A. Sayre, of New York, read a paper on the treatment of rotary lateral curvature of the spine by extension, suspension of the body, and retention by the plaster-of-Paris bandage. The doctor made a practical demonstration, fully illustrating his treatment. He was listened to attentively throughout. Dr. Sayre expressed himself as being under special obligations to Drs. Vanderveer and Balch for their assistance, and to Dr. Hun for the case.

A recess was then taken for the purpose of having the members of the Society photographed in a body.

The officers and members grouped themselves on the front steps of the Capitol, and were photographed by Churchill.

The society re-convened at 4:35.

On motion of Dr. Squibb, the action of the Society Tuesday, in reference to the prize essay, was re-considered, and the subject referred back to the committee, as it has been discovered that the conditions of the prize had not been complied with, with power to report at the next annual meeting.

Dr. Bailey presented the names of the following gentlemen, who were invited to take seats on the floor and participate in the discussion: S. Delamater, A. Ennis, Jas. P. Alexander, W. H. T. Reynold, A. P. Ten Eyck, Desault Guernsey, Smith Baker, A. S. Cummings, R. H. Starkweather, H. A. Crary, Wm. T. Baynes, R. H. Sabin, L. R. Boyce, W. A. Hall, J. L. Archaumbault, Z. Rousseau.

Dr. Kendall was called to the chair. A discussion then ensued upon Dr. Sayre's paper, in which Drs. Moore, of Rochester, and Hutchinson, of Brooklyn, participated.

Dr. Moore asked the following questions for the sake of information: At what age did Dr. Sayre propose to discontinue this treatment for lateral curvature? Would he adopt this plan of treatment at the age of 20 or 25 years? As a rule, lateral curvature commenced about the time of puberty, and at that time the ligaments were capable of being stretched, and the bones were not very firm, and he was of the opinion it was well established that after the age of seventeen it was extremely difficult to make any impression upon the spine; and whatever was done in way of correcting deformities, was best done before that period in life. Again, in looking at the specimen exhibited, as well as other specimens, Dr. Moore had found so much absorption of the bodies of the vertebræ had occurred that the condition came under the head of organic change affecting the hard parts, and the question arose whether it was possible by any plan of treatment to cause absorption of the opposite side of the bodies, and thereby rectify the condition permanently. Dr. Moore asked these questions, because, thus far, the plan of treatment struck him pleasantly, and it seemed to mark a new step in the treatment of this class of cases. Again, how much exercise could the patient take in the open air? Could it be increased, or not?

Dr. Sayre replied that at present it was impossible to answer Dr. Moore's questions with very great certainty, because the plan of treatment had not been in use a sufficient length of time to furnish positive conclusions. As far as he had employed it, great satisfaction had been experienced by the patients; and if compelled to wear a jacket in lifetime, they were better off, according to their own statements. As far as age was concerned, Dr. Sayre had resorted to it in a man aged forty, in which case he made section of

the latissimus dorsi muscle, in order that the deformity might be almost completely overcome, and the result had been eminently satisfactory, because the spine was made nearly straight. The angles of the ribs, however, in such cases, would probably always remain somewhat more prominent than normal. As far as exercise was concerned, the patients were able to exercise more freely than before the dressing was applied.

Dr. Moore remarked that the question still existed in his mind, and had not been entirely set at rest by Dr. Sayre's experience. He maintained that the bodies of the vertebræ were absorbed to a certain extent in the specimens exhibited, and that in the cases in which the deformity was most marked they might not have more than one-half their normal thickness upon one side. The question then arose, if measures were adopted to bring the spine straight, did absorption of the bodies of the vertebræ upon opposite side take place, or was there a deposit of new material to compensate for the original loss in thickness? Dr. Moore farther referred to the straightening of the spine by making section of muscles as practised by Guerin long ago, but the spine was left unduly flexible in consequence. The doctor doubted very much the propriety of instituting any plan of treatment with the view of rectifying the deformity after the patient had reached the age of twenty or twenty-five years.

Dr. Sayre thought it quite probable that the bones themselves could not be restored; but that by restoring the spine to its natural position as much as possible, the weight was brought to bear upon the side opposite to that on which the absorption of the bones had taken place. Then, if absorption had taken place, as the result of superincumbent weight in one instance, why might it not occur in the other? The short time during which the treatment had been used, did not permit any positive conclusions upon these and many other important questions. The subject was open for study.

Dr. Hutchinson, of Brooklyn, regarded it as settled that absorption of the sides of the bodies of the vertebræ took place to a greater or less extent; and in the specimens he had in his hand, it was thought to have taken place to the extent of one-third the normal thickness, and yet it had not been a bad case of lateral curvature. He farther remarked that he should expect a good deal from the plan of treatment proposed by Dr. Sayre, and that if any change at all was produced in the bony structure it would be in the way of absorption rather than filling of the interspace between the bodies of the vertebræ with new material.

Immediately following the discussion, Dr. Henry D. Noyes, of New York, presented two papers, viz.: Cure of Blepharoplasty by a Special Method; Treatment of Diseases of the Lachrymal Duct, with some New Suggestions.

Dr. Wey, from the Business Committee, announced the reception of a communication from Dr. E. Seguin, of New York, which was read by the Secretary, and, upon motion of Dr. Squibb, referred to the delegation to the International Medical Congress.

Dr. Wey also announced the reception of a communication from the Boston Society of Civil Engineers, which took a similar reference. Both communications referred to the adoption of a uniform system of weights, measures, and thermometric scales.

Dr. Castle suggested that if the Society endorsed the adoption of the metric system of weights and measures, it should make it practical by incorporating it in the Transactions. Unless practical use was made of it, it would remain a theory forever.

Dr. Wey announced the reception of a communication from the State Dental Society; which, upon motion by Dr. Graves, of Steuben, was referred to the Committee on Ethics.

Dr. Husted made a report from the Auditing Committee upon the Treasurer's account, which was accepted and adopted.

Dr. Graves, of Corning, read a paper upon the

NATURE, ORIGIN, AND PROGRESS OF DISEASE IN THE HUMAN BODY.

Dr. L. J. Ames, of Mount Morris, was called to the Chair, and

Dr. Kendall proceeded to read the history of a case of

TETANUS FOLLOWING MISCARRIAGE.

Hydrate of chloral was regarded as the remedy which had most effect in producing a cure in Dr. Kendall's case, although morphine, whiskey, counter-irritation to the spine, and chloroform were all employed.

The Society then took a recess until 8 P.M., to listen to the President's address on the subject: "Medical Men and Medical Matters of 1776."

EVENING SESSION.

At eight o'clock the Society reassembled to listen to the address of the President, Dr. Rochester. The attendance was very large, the chamber being filled by the members of the Society and citizens. The address was a refined, interesting, and comprehensive *résumé* of the national medical history of the revolutionary period, and was listened to with marked attention throughout.

At the conclusion of the address, the Society proceeded to the Delavan House, and indulged in a banquet given by Dr. Rochester. It was a happy affair, and highly flavored with a sparkling social element.

THURSDAY, JUNE 22.—THIRD DAY.

The Society was called to order by the President, and prayer was offered by Rev. Dr. Reese.

In absence of the Committee on Credentials, Dr. Burr, of Binghamton, was designated to act in that capacity.

Dr. Bailey presented the following names for membership by invitation: Drs. F. A. Munson and Keegan, of Albany, and C. A. Bucklin, of Lansingburgh.

Dr. Robert Newman, of New York, presented his report as delegate to the New Jersey State Medical Society, which was accepted and adopted.

The following telegram was received by the President:

PUT-IN BAY, O., June 21.

TO THE N. Y. STATE MED. SOCIETY:

The Ohio State Medical Society sends greeting to your Society in endeavoring to promote progress in medicine.

President Rochester responded.

The President announced the following

COMMITTEE ON HYGIENE:

Drs. A. N. Bell, S. O. Vanderpoel, H. D. Didama, E. V. Stoddard, C. R. Agnew, W. C. Wey, and J. Foster Jenkins.

Dr. Judson B. Andrews, from the Committee on

OFFICERS ELECT.

Nominations, made the following report:

President—Dr. E. R. Squibb, of Brooklyn.

Vice-President—Dr. J. V. Kendall, of Baldwinsville.

Secretary—Dr. Edward R. Hun, of Albany.

Treasurer—Dr. Charles H. Porter, of Albany.

Censors—Southern District, E.R. Peaslee, New York; E. H. Parker, Poughkeepsie; Ellsworth Eliot, New York. Eastern District, Henry B. Whiton, Troy; Jas. L. Babcock, Albany; John P. Sharer, Little Falls. Middle District, M. M. Bagg, Utica; Geo. W. Cooke, Otego; C. G. Bacon, Fulton. Western District, C. C. Wyckoff, Buffalo; Harvey Jewett, Canandaigua; Caleb Green, Homer.

Committee on Correspondence—First District, Thos. Addis Emmet, New York; 2d, Wm. P. Townsend, Goshen; 3d, W. P. Seymour, Troy; 4th, Taber B. Reynolds, Saratoga; 5th, Samuel G. Wolcott, Utica; 6th, John G. Orton, Binghamton; 7th, Harvey B. Wilbur, Syracuse; 8th, Charles E. Rider, Rochester.

Permanent Members—First District, J. H. Hobart Burge, Kings; Wm. M. Blakeman, New York; 2d, Solomon Van Etten, Orange, Desault Guernsey, Dutchess; 3d, Daniel D. Bucklin, Rensselaer; Albert Vanderveer, Albany; 4th, Eugene Beach, Fulton, E. D. Ferguson, Essex; 5th, Frank D. Beebe, Madison, Joseph E. West, Oneida; 6th, George Douglass, Chenango, A. H. Crittenden, Steuben; 7th, A. H. Cumnings, Cayuga, Wm. Oliver, Yates; 8th, Wm. B. Ely, Monroe, George Abbott, Erie.

Eligible for Permanent Members—L. DeForest Woodruff, New York; J. F. Chapman, Westchester; B. A. Mynderse, Schenectady; C. G. Bacon, Saratoga; A. H. Crosby, Lewis; Loren J. Ames, Livingston; A. F. Sheldon, Wayne; Wm. Vosburgh, Wayne; J. C. Green, Erie.

Eligible for Election to Honorary Membership—W. A. F. Browne, Dumfries, Scotland; S. Weir Mitchell, Philadelphia.

For Honorary Degree of Doctor of Medicine—Samuel M. Crawford and Henry C. Seeley, of Orange.

Delegates to American Medical Association—C. S. Wood, J. W. S. Gouley, J. F. Miner, G. M. Smith, G. S. Winston, T. A. Emmet, L. De F. Woodruff, New York; J. C. Hutchinson, E. R. Squibb, A. N. Bell, Kings; G. J. Fisher, J. F. Jenkins, Westchester; E. H. Parker, Dutchess; H. B. Whiton, M. H. Burton, W. P. Seymour, Rensselaer; E. R. Hun, Chas. H. Porter, Albany; J. P. Sharer, Herkimer; B. F. Sherman, St. Lawrence; E. Beach, F. Burdick, Fulton; J. P. Gray, T. M. Flandreau, Oneida; F. S. Low, Oswego; G. W. Cooke, Otsego; F. Hyde, Cortland; H. N. Eastman, Tioga; Geo. Burr, Broome; T. H. Squire, Chemung; C. G. Pomeroy, Wayne; H. C. Jewett, W. T. Swart, Ontario; L. B. Cotes, Genesee; C. C. Wyckoff, Wm. C. Phelps, Wm. Gould, Erie.

Delegates to the Pennsylvania State Society—Wm. C. Wey, Chemung; Solomon Van Etten, Orange.

Delegates to the Massachusetts State Society—J. F. Jenkins, Westchester; J. L. Banks, H. P. Farnham, New York; Walter B. Chase, Greene.

Delegates to the Connecticut State Society—Alex. Hutchins, Kings; G. W. Bradford, Cortland.

Delegates to the New Jersey State Society—John Ball, Kings; H. D. Noyes, New York; R. H. Ward, Rensselaer.

Delegates to the New Hampshire State Society—Wm. Govan, Rockland; L. D. Bulkley, New York.

Delegates to Vermont State Society—Thompson Burton, Montgomery.

Delegates to Rhode Island State Society—Chas. M. Allin, New York.

Delegates to Canadian Medical Society—B. F. Sherman, St. Lawrence; H. G. P. Spencer, Jefferson.

Committee on Prize Essay—Henry W. Dean, Wm. S. Ely, Monroe; Julius F. Miner, Erie.

Committee on Publication—E. R. Hun, Chas. H. Porter, Wm. H. Bailey, Albany.

Committee on By-Laws—Wm. C. Wey, Chemung; E. R. Hun, Wm. H. Bailey, Albany.

Censor of Syracuse University—B. F. Sherman, St. Lawrence.

On motion by Dr. Burr, the report was accepted, and the Secretary instructed to cast an affirmative vote for the four highest officers.

Dr. Burr then moved that the remaining names in nomination be declared elected. Carried.

Dr. E. M. Moore, chairman of the Committee on Ethics, made the following report:

In regard to a communication relative to the absorption of physicians resident in Rensselaer county by the County Society of Albany and their refusing allegiance to the Rensselaer Society, the committee report that they find no express legislation on the subject, but entertain the opinion that the Constitution of the State Society was organized so strictly upon that of the political plan of the State that the territorial lines must govern the membership.

In regard to a communication from three members of the Ulster Society, complaining of the action of the Society in reprimanding a member for refusing to consult with another in good standing, the committee report that they know of no power in the Medical Society to compel a physician to consult with another physician. Any one may choose his companion as well as his patients.

In regard to a communication from the State Dental Society, the committee urge all members of the State Medical Society to be governed in their recommendation of dentists to their patients by the endorsement of the Dental Society. The report was adopted.

INDEPENDENT EXAMINATIONS.

Dr. E. M. Moore presented the following resolution:

Resolved, That a committee be appointed at the request of such Medical Colleges as may prefer such request, to be present at the examination of their students, made to determine their qualifications to enter the profession; also, that the committee be six in number, and be appointed by the President of the Society.

Dr. Moore spoke at some length upon the resolution, and it was also discussed by Drs. Bell, Prout, and Squibb. The resolution was referred to a committee of three, to be appointed by the Chair, to be reported upon on the second day of the next annual meeting at 12 o'clock.

The President named the following gentlemen to serve upon such committee: Drs. E. M. Moore and H. W. Dean, of Rochester; and C. C. Wyckoff, of Buffalo.

The report of the Committee on permanent membership was then taken up, and after an almost interminable discussion was amended in certain particulars, and adopted.

Section One was adopted as reported.

Section Two was stricken out.

Section Three was adopted.

Section Four gave rise to considerable discussion, but was finally adopted.

Section Five was adopted.

Section Six again gave rise to discussion, and Dr. Bailey doubted its legality. It was finally adopted.

Section Seven was adopted.

Section Eight was amended so that those members removing from the State should be regarded as non-resident permanent members having all the rights and privileges of honorary members, and then adopted.

Dr. H. D. Noyes offered the following additional section, which was adopted.

Section Nine. In case permanent members have failed for three years to pay their assessments, they shall be specially notified by the Treasurer and Secretary of the existence and operation of these By-Laws.

The report as a whole was adopted, and the Secretary instructed to obtain such legislation as might be necessary to assist in carrying out its provisions.

Dr. Squibb offered the following resolution, which was adopted:

Resolved, That the Committee on Publication be authorized to send presentation copies of the Transactions to the medical journals, domestic and foreign, to such individuals as may be interested in the contents of the volume, as may in their judgment be for the interests of the Society.

Dr. Andrews, of Utica, offered a resolution tendering a vote of thanks to the President for the able and impartial manner in which he had directed the business affairs of the meeting, and also for the pleasant social entertainment extended to the members and delegates at the Delavan House on the evening of the second day.

The resolution was unanimously adopted, and Dr. Rochester responded with appropriate remarks. The minutes of the morning session were then read and approved, and the Society adjourned to meet in Albany at 11 A.M. on the third Tuesday in June, 1877.

ASSOCIATION OF THE REPRESENTATIVES OF AMERICAN MEDICAL COLLEGES.

Held at Philadelphia, June 2d and 3d, 1876.

A convention of representatives of numerous medical colleges of the United States was held in the hall of the Jefferson Medical College, of Philadelphia, June 2d and 3d, 1876, in pursuance of the following call:

Louisville, Ky., May 15, 1876.

Following a general correspondence with the various medical colleges of the United States, the undersigned issue this call for a convention, to be held in Philadelphia, on Friday, June 2, 1876, four days in advance of the meeting of the American Medical Association. The object of the convention is to consider all matters relating to reform in medical college work.

That decided results may be reached, the faculty of each college is requested to send one or more delegates, clothed with *plenary* powers to determine final action on every question.

Should any college find it impracticable to send a representative, it is hoped that it will set forth fully by letter to the convention the views it may hold touching the suppression of existing evils and methods of practical improvement.

Officers of the following colleges have informally signified their hearty approval of the movement:

Jefferson Medical College, College of Physicians and Surgeons, N. Y., Bellevue Hospital Medical College, Ohio Medical College, Miami Medical College, Rush Medical College, Detroit Medical College, Louisville Hospital Medical College, Medical Department of University of Louisville, St. Louis Medical College, Keokuk Medical College, Cleveland Medical College, Starling Medical College, Medical Department of Georgetown College, Medical Department of Columbian University, Long Island College Hospital, Medical Department of Syracuse University, Evansville Medical College, Indiana Medical College, Medical Department of University of Nashville, Atlanta Medical College, Mobile Medical College, Savannah Medical College, Augusta Medical College.

The convention will be called to order in the hall of the Jefferson Medical College at 11 o'clock A.M., on the day above named.

J. B. Biddle, M.D., Jefferson Medical College.
Wm. H. Mussey, M.D., Miami Medical College.
John T. Hodgen, M.D., St. Louis Medical College.
J. Adams Allen, M.D., Rush Medical College.
W. T. Briggs, M.D., Medical Department University of Nashville.
J. M. Bodine, M.D., Medical Department University of Louisville.

At the hour named the following representatives assembled:

Jefferson Medical College—Prof. J. B. Biddle and Prof. S. D. Gross.

Medical Department University of Pennsylvania—Prof. R. E. Rogers.

College Physicians and Surgeons of New York—Prof. Edward Curtis.

Medical Department University of Louisville—Prof. L. P. Yandell, Jr., and Prof. J. M. Bodine.

Hospital College of Medicine of Louisville—Prof. J. A. Larabee and Prof. T. C. Wilson.

Long Island Hospital Medical College—Prof. J. H. Raymond.

Medical Department University of Iowa—Prof. E. Clapp.

College of Physicians and Surgeons Syracuse University—Prof. H. B. Wilbur and Prof. Van Duyn.

Chicago Medical College—Prof. L. Curtis.

Medical Department University of Georgia—Prof. E. Geddings.

Indiana Medical College—Prof. T. B. Harvey and Prof. L. D. Waterman.

Medical Department University of Wooster—Prof. W. J. Scott.

Cleveland Medical College—Prof. J. H. Bennett and Prof. Heims.

Detroit Medical College—Prof. E. W. Jenks and Prof. L. Connor.

Starling Medical College—Prof. S. Loving.

Medical Department University of Vermont—Prof. H. D. Holton.

St. Louis Medical College—Prof. J. L. B. Alleyne.

Atlanta Medical College—Prof. W. F. Westmoreland.

Medical Department University of Nashville—Prof. W. T. Briggs.

Medical Department Vanderbilt University—Prof. T. A. Atchison.

Missouri Medical College—Prof. A. P. Lankford.

Keokuk College Physicians and Surgeons—Prof. J. J. M. Angier.

Columbus Medical College—Prof. J. F. Baldwin.

On motion of Prof. Yandell, Prof. J. B. Biddle was elected President of the convention, and on motion of Prof. Bennett, Prof. Leartus Connor was elected Secretary.

On motion of Prof. E. Curtis, it was

Resolved, That the action of the convention shall not be considered binding upon the colleges represented unless endorsed by their respective faculties.

On motion of Prof. Gross, it was

Resolved, That a committee be appointed to submit business for the consideration of the convention, to report at the afternoon session.

The chair appointed as this committee, Profs. Bodine, Gross, Geddings, Holton and Scott.

The convention adjourned until 4 P.M.

Pursuant to adjournment, the convention reassembled at 4 P.M., the President in the chair.

The minutes of the last meeting were read and approved.

PROF. BODINE, from the committee to prepare business for the convention, reported the following questions for its consideration:

THE BENEFICIARY SYSTEM.

1. Shall the beneficiary system, with its present abuses, be condemned or endorsed?

After discussion, on motion of PROF. E. CURTIS, the following preamble and resolutions were adopted with reference to question first:

Whereas, The practice of reducing or remitting in individual cases the established fees of a college has the objectionable feature of discriminating between students who may be equally deserving, and opening the door to possible gross abuses; therefore,

Resolved, first, That this convention regards the above privilege as one to be deprecated in general, and, if put into practice at all, to be exercised both rarely and reluctantly, and only in unusual circumstances, and after unsolicited application by proven deserving candidates.

Resolved, second, That anything like a wholesale system of such reduction or remission of established fees, or any open solicitation of recipients of such favors, be regarded as in the highest degree improper, and that any college indulging in such practices deserves to forfeit its place on the *ad eundem* list of medical colleges.

THE SHORT-TERM SYSTEM.

Question 2. Shall two consecutive courses of lectures in one year entitle students to become candidates for graduation?

On motion of PROF. E. CURTIS, it was

Resolved, That it is the opinion of this convention that no two consecutive sets of lecture tickets shall be regarded as fulfilling the usual pre-requisites of instruction for graduation, where the time between the beginning of the first course and the end of the second is less than fifteen months.

BLANK DIPLOMAS.

Question 3. Shall any faculty, under any circumstances, issue a diploma not bearing the graduate's name?

On motion of PROF. WATERMAN, it was

Resolved, That no medical faculty should issue a diploma not bearing the graduate's name.

It was ordered that the meetings of the convention shall be at 10 A.M. and 4 P.M.

On motion, the convention adjourned.

The convention reassembled on Saturday, June 3d, at 10 A.M., the President in the chair.

The minutes of the previous meeting were read and approved.

On motion of PROF. L. P. YANDELL, Jr., the regular order of business was suspended, and communications were read from the faculties of the following medical colleges: Louisville Medical College, Kentucky School of Medicine, Evansville Medical College, Rush Medical College, Medical Department University Louisiana, Medical School of Harvard University, Savannah Medical College, Cincinnati College of Medicine and Surgery, Medical College of State of South Carolina.

On motion of PROF. ATCHISON, these communications were placed on file.

Question 4. Shall this convention resolve itself into a permanent organization?

On motion of PROF. ATCHISON, it was

Resolved, That the question be referred to a committee of five, to report at the afternoon session.

The chair appointed as this committee Profs. Atchison, L. Curtis, E. Curtis, Yandell and Scott.

On motion of PROF. ROGERS, the President and Secretary of the Convention and Prof. Atchison were appointed a committee on publication.

Question 5. Is there any reason why the customary diploma fee shall be abolished?

DIPLOMA FEE.

On motion of PROF. ROGERS, it was

Resolved, That it is the sense of the convention that the diploma fee should not be abolished.

GRADED COURSES.

Question 6. Is it advisable to adopt a graded course of study?

On motion of PROF. BODINE, the following preamble and resolution were adopted in reference to this question:

Whereas, A knowledge of the elementary branches of medicine should precede a study of the practical branches.

Resolved, That, in the hope of inducing students to prolong and systematize their studies, this convention recommends to all medical colleges to offer to students the option of three courses of lectures, after a plan similar to the following: Students who have attended two full courses of lectures on anatomy, chemistry, materia medica and physiology, may be examined upon any of these subjects at the end of their second course. During their third course such students may devote themselves to the lectures upon the theory and practice of medicine, surgery, obstetrics, and diseases of women and children, upon which subjects only they shall be examined at the final examination for the degree of M.D.—their standing, however, to be determined by the results of both examinations.

On motion, adjourned till 4 P.M.

The convention reassembled at four P.M., the President in the chair. The minutes of the last meeting were read and approved.

PROF. ATCHISON, from the committee to whom the subject of permanent organization was referred, reported the following resolutions:

Resolved, 1. That this *convention* now proceed to form a Provisional Association of American Medical Colleges, under its present officers.

Resolved, 2. That when the Association adjourns, it shall adjourn to meet at the call of its President.

Resolved, 3. That the various medical colleges be invited to take into consideration the project of forming, at the next meeting of this Provisional Association, a permanent Association of American Medical Colleges.

Resolved, 4. That for the furtherance of this object, a committee of three be appointed at this meeting to confer by letter with the various colleges, and invite their views on the proper object and plan of such proposed organization; and upon the receipt of the same, to draft a constitution and by-laws for a permanent Association, to be submitted at the next meeting of this Association.

Resolved, 5. That the advisory resolutions upon matters of college policy passed by this convention be printed and forwarded to all regular medical colleges in the United States for their consideration.

The Chair appointed as committee to carry out the foregoing resolutions Prof. T. A. Atchison, Prof. Edward Curtis, and Prof. L. P. Yandell, Jr.

These resolutions were adopted, and the convention resolved itself into the Provisional Association of American Medical Colleges.

Question 7. Is it proper for a regular college to have any kind of alliance with homœopathy?

IRREGULAR MEDICINE.

On motion of PROF. ATCHISON, it was unanimously

Resolved, That, in the opinion of this Association, medical colleges ought not to recognize or hold fellowship with any school or its alumni in which irregular medicine is taught as a part of the curriculum.

Question 8. Can college fees be made uniform?

On motion of PROF. GEDDINGS, this question was referred to a committee of five, to report at the meeting of the Association to be held in 1877.

The Chair appointed Profs. Geddings, Gross, Angier, E. Curtis, and L. Curtis, this committee.

MEDICAL EXAMINATIONS.

On motion of PROF. BIDDLE, the following resolution was unanimously adopted:

No degree in medicine should be conferred, under any circumstances, except after an examination in person of the candidate upon all the branches of medicine.

On motion of PROF. ATCHISON, the thanks of the Association were tendered to the President for the able and impartial manner in which he had discharged the duties of the chair.

On motion of PROF. YANDELL, the thanks of the Association were tendered to the Secretary for his efficient services.

On motion of PROF. LARRABEE, the thanks of the Association were tendered to Jefferson Medical College for the use of the hall and other courtesies.

On motion, the Association adjourned to meet at the call of the President.

J. B. BIDDLE, M.D., *President.*
LEARTUS CONNOR, M.D., *Secretary.*

ASSOCIATION OF SUPERINTENDENTS OF AMERICAN ASYLUMS FOR THE INSANE.

Thirteenth Annual Meeting, held at Philadelphia, June 12, 13, 14, 15, 16, 1876.

THE thirteenth meeting of this Association was held at Continental Hotel, Philadelphia, commencing June 12th. Dr. Clement A. Walker, of Boston, Vice-President, occupied the chair, until the arrival of Dr. C. H. Nichols, of Washington, on the second day. The first session was occupied in the hearing of reports from the different asylums throughout the country.

PRESIDENT'S ADDRESS.

DR. C. H. NICHOLS, Superintendent of the Government Hospital for the Insane, at Washington, arrived on the second day, and entered upon his duties as chairman. In regard to the investigation of the affairs of his institution by the Congressional Committee, he said that the sensational press had kept the public pretty well informed on all the unfavorable testimony. He had kept the members of the Association informed of the favorable testimony by papers he had sent them, and he did not think it important for him to furnish the testimony to the public. He had been the disbursing agent of the institution since the first appropriation had been made, and had disbursed all the funds except for the purchase of land. He had called four well-known business men to examine into his accounts, but the committee had refused to hear their evidence, the chairman remarking that no serious charge had been made against his honesty as a financial agent of the Government. He did not consider mere financial honesty as the highest qualification for a Superintendent of a hospital for the insane; but judgment on that subject was yet to be passed by the committee.

DR. JAMES H. DENNY, of Boston, exhibited a set of anatomical preparations of sections of the brain, made by himself in Vienna, and he urged the importance of having in all institutions a full set of sections of the normal brain for making comparisons in cases of post-mortem examinations of deceased patients.

MENTAL AND PHYSICAL SYMPTOMS OF CEREBRAL DISEASES.

DR. JOHN P. GRAY, of the State Lunatic Asylum at Utica, New York, then read a paper on "Mental and Physical Symptoms in Cerebral Diseases, and their Relations to Insanity."

CRIMINAL INSANITY.

In the evening the Association met again at the Continental to hear a paper by DR. ISAAC RAY, of Providence, on "How far Insanity should be received as an Excuse for Crime." He commenced by alluding to the English decisions in the cases of insane criminals, which now stand as law, but which were founded on mistaken estimates of insanity, and were really of little value in the light of recent scientific researches.

The plea of insanity, he said, did not meet with much favor among jurists and lawyers, and still less when they were informed that insane persons generally know right from wrong, and are capable of hatred and malice, thus apparently furnishing all the elements of crime. The lawyers, in their imperfect knowledge of the subject of insanity, make two great mistakes, one of which is that an insane person may be excused for a criminal act prompted by a delusion only so far as the provocation he imagined would excuse him if his delusion were merely true. This he declared was directly contradicted by the experiences of science. There was nothing more probable than that the person who imagined that his neighbor had been telling bad stories about him should also imagine that he was justified in taking his neighbor's life.

The other mistake made by lawyers was to leave out of the account altogether the moral faculties of our nature—the sentiments, feelings, and emotions. Disease of the moral faculties, he said, often resembled moral depravity. The question should not be, "Did he know the difference between right and wrong?" "Did he evince forethought and intention in his preparation for the crime?" but "Could he see the moral complexion of his act in its true colors?" "Had he the power to pursue the right and resist the wrong?" The existence of insanity, even in the smallest degree, being shown, it should be for the other side to show that the insanity did *not* influence the person to the commission of crime. This was now the rule in civil cases, where, if the insanity be shown, it was for the party seeking to establish the legality of the will or contract to show that the maker had recovered.

There was a tendency now to the belief that the plea of insanity was becoming too common, and that the punishment of the insane may prevent offences. To those familiar with insanity the falsity of this was beyond question. It impaired the freedom of the will. It blunted the sense of right and wrong and diminished the power of self control, and in every instance of crime there was room for the belief that the act would

not have been committed but for the presence of the disease. Very few of the insane would believe that they were insane, and, therefore, would not be prompted to crime by the knowledge of the immunity of the insane, nor would they be restrained by the knowledge that the insane were punished, as they insisted on considering themselves entirely outside of that class. As we stand now, our Legislatures were powerless, and the rules laid down by our courts were irrelevant, impracticable, and inconsistent; and this would remain so until the question of insanity should be merely a question of fact, to be established. Our judges, he said, were bound to make themselves acquainted with the nature of insanity by every means in their power, and to charge their juries from the result of their knowledge rather than by servile repetition of what has weight only because it has been said before. The Doctor closed by speaking highly of the value of expert testimony in cases of insanity.

An invitation to the members to visit the Academy of Natural Science at their leisure was read and accepted.

MENTAL AND PHYSICAL SYMPTOMS OF INSANITY.

The morning session of the third day was occupied in a discussion of Dr. Gray's paper on "Mental and Physical Symptoms in Cerebral Diseases and their Relations to Insanity."

Dr. Mark Ranney, of the Hospital of the Insane, Mount Pleasant, Iowa, believed that softening of the brain was much less common than was popularly supposed.

Dr. Isaac Ray, of Philadelphia, said that the influence of Dr. Gray's paper would be valuable in directing attention to the study of a class of cases to which too little attention had been given, simply because the opportunity did not present itself so frequently in the asylums. The phrase "Softening of the brain" was one of the most abused terms in our nomenclature. Softening was one of the rarest forms of cerebral diseases. Any other lesion of the brain was more frequent. He approved generally of the therapeutics indicated by Dr. Gray, who disapproved of depletion even in those cases in which forty years ago bleeding would have been the first thing resorted to. In cases of threatened congestion he believed trouble could often be prevented by depletion, but the moment for its profitable use passed very soon.

Dr. Walter Kempster, of the North Wisconsin Hospital for the Insane, Oshkosh, Wis., remarked that in every case of softening in which he had made post-mortem examinations, he had found miliary aneurisms in the midst of the softened tissue, their usual size being about one forty-fifth of an inch in diameter.

Dr. Edwin A. Kilbourne, of the Hospital for the Insane, at Elgin, Ill., was of the opinion that embolic softening of the cerebral hemispheres might exist without impairing the mental activity.

Dr. A. E. MacDonald, of the City Asylum for the Insane, Ward's Island, N. Y., said that, on post-mortem examinations he had found a great diversity of pathological appearances in cases where death had resulted after the same class of symptoms.

Dr. R. F. Baldwin, of the Western Lunatic Asylum, at Staunton, Va., described a post mortem examination he had made in the case of a negro who received a blow on the head, which he (the Doctor) considered trifling. He was surprised to hear of the negro's death the morning after the blow, and on the post mortem examination he found the whole anterior cerebrum in a state of softening. A spicula of bone an inch and a half long protruded from the frontal bone directly into the brain substance. This was caused by the kick of a horse received a year before. He cited this to show how largely brain diseases may exist without affecting the faculties.

The Association then adjourned until the afternoon.

On reassembling in the afternoon the Committee on Time and Place of the Next Meeting reported in favor of St. Louis, Mo., the time to be the last Tuesday in May, 1877. The report was unanimously adopted.

DELEGATES TO INTERNATIONAL MEDICAL CONGRESS.

The following delegates to the International Medical Congress were next appointed:

Dr. T. S. Kirkbride, of Philadelphia; Dr. Isaac Ray, of Philadelphia; Dr. John Curwin, of Harrisburg; Dr. C. A. Walker, of Boston, Mass.; Dr. Pliny Earle, of Northampton, Mass.; Dr. John P. Gray, of Utica, N. Y.; Dr. D. Tilden Brown, of New York; Dr. H. A. Buttolph, of Morristown, N. J.; Dr. Orpheus Evarts, of Indianapolis, Ind.; Dr Charles H. Nichols, of Washington, D. C.; Dr. Walter Kempster, of Oshkosh, Wis.; Dr. C. N. Hughes, of St. Louis, Mo.; Dr. H. C. Carrell, of Jacksonville, Ill.; Dr. J. H. Callender, of Nashville, Tenn.; Dr. W. S. Chipley, of Cincinnati, Ohio; Dr. James Rodman, of Hopkinsville, Ky.; Dr. Eugene Grissom, of Raleigh, N. C.; Dr. C. K. Bartlett, of St. Peter, Minn.; Dr. A. M. Shew, of Middletown, Conn.; Dr. James R. DeWolf, of Halifax, N. S.

CRIMINAL INSANITY.

The discussion of Dr. Isaac Ray's paper on Criminal Insanity being the next in order of business,

Dr. John P. Gray, of the State Lunatic Asylum of Utica, N. Y., said that present experience showed that there was a far greater danger of the guilty escaping punishment by feigning insanity than of the insane being improperly punished.

The great desideratum, he said, was to get the expert witnesses nearer the Court. In New York, when the accused plead insanity as his entire excuse, the Court appointed a commission of experts to discover whether the accused was insane when he committed the crime, and in no instance yet had the judgment of such a commission been overruled by the Court. This, he considered, a far better plan than the examination of an expert witness before a jury. The commission he spoke of decided whether the accused was a fit person to be tried at all.

The judges were careful in the appointment of the commissioners, and they were required to submit a report, embodying not only their opinion, but all the testimony taken before them, so that the opinion may be examined by the Court in the light of the evidence. This plan, he said, did away with the disgrace to the profession, now so often seen, of the directly contradictory testimony of experts, caused by the same case being presented to two different expert witnesses in entirely different lights.

Dr. Richard Gundry, of the South East Hospital for the Insane, Athens, Ohio, said that offences were often committed by persons who were perfectly irresponsible at the time, although they had no disease of the brain. Suppose a man had the gout, and in a paroxysm of the disease he assaulted his attendant; that man was as free from responsibility as though he were the most confirmed lunatic alive.

Dr. W. S. Chipman, of the Cincinnati Sanitarium, said that from his observation one of the greatest evils connected with medical jurisprudence was that persons were often called as experts who were not experts. As for hypothetical cases, he had always refused to an-

swer in court any questions founded upon them, because what might be evidence of insanity in one person might not be in any degree so in another. He had always refused to answer questions that were not founded on actual facts, and he had always been sustained by the Court.

Dr. A. E. McDonald, of the City Asylum for the Insane, at Ward's Island, New York, thought the Association should put itself on record in opposition to bringing insane persons before juries at all, inasmuch as the New York plan of a commission of experts had proved itself to be so much superior.

Dr. R. L. Parsons, of the City Lunatic Asylum, at Blackwell's Island, New York, said that in the case of Scannell, in New York, the attorney for the defence made up a hypothetical case and presented it to the medical expert, who testified that it was undoubtedly a case of insanity. The District Attorney then presented a hypothetical case to another expert, who testified that the person described manifested no signs of insanity.

Dr. Ray thought that the practice in Maine was better than the New York plan, of a commission of experts before trial. In Maine, if the accused plead insanity as his only excuse, he was sent for a time to the insane hospital for purposes of observation.

Dr. Henry M. Harlan, of the Hospital for the Insane, Augusta, Maine, described the working of the law requiring accused persons in whose cases the plea of insanity has been offered, to be placed in the Asylum of Observation. He said the law worked very well, except when any of the persons sent in for observation were found not to be insane, in which case they proved to be very troublesome, and the mingling of these sane criminals with the insane patients was a great evil. He had urged the establishment of another institution where such persons could be sent for purposes of observation, and to which persons acquitted on the ground of insanity could be committed.

THE DEPLORABLY CROWDED CONDITION OF PHILADELPHIA ASYLUM FOR THE INSANE.

The morning of the fourth day was occupied for the most part with an expression of opinion regarding the deplorable condition of the insane at the Almshouse of Philadelphia.

Dr. Ray spoke of the outrageous condition of the insane at the Almshouse, and said he was too tender of the good reputation of the city to speak of the place as it deserved. The insane of the city of Philadelphia were not by any means cared for as well as those of other cities. The violent patients were crowded together, three or four each in small 10×12 rooms, and the entire concern was crowded to overflowing. This condition of things, he said, was the result of mere parsimony. It was simply because the city did not choose to furnish the proper accommodations for their unfortunate population. It was the most niggardly and contemptible parsimony, that while the city spent millions in parks and other places of amusement, the insane were kept in this miserable way, at an expense of about $1.80 a week. Under a storm of indignation raised by the newspapers a short time ago, Councils put up a set of shanties entirely unfitted for the purpose, having no strength, with wards that a child could kick the sides out of, instead of providing the proper increase in accommodations. There was no reason, he said, why the insane of the city of Philadelphia should not be cared for by the State as well as the insane of Pittsburgh or Reading, and until the matter was taken out of the hands of the City Councils, nothing would probably be done. A State institution seemed to be the only way out of the difficulty.

Dr. Kirkbride confirmed all that had been said by Dr. Ray, and said that for a quarter of a century he and many others had been urging an improvement in the accommodations for the insane at the Almshouse, but without effect, and they concluded that the only way to even obtain an improvement was to let things go on until they had become so shametully bad that the public would rise in horror at the spectacle, and he thought that condition of affairs had very nearly arrived.

Dr. John Curwen, of the Pennsylvania State Lunatic Hospital, at Harrisburg, Pa., declared that he had always been in favor of establishing a State Hospital in Philadelphia, and the principal reason why the project to establish one in Philadelphia had failed, was because certain parties in Philadelphia wanted to handle the money for the buildings, and the Legislature did not think them the proper ones.

The matter was then, on motion of Dr. Curwen, referred to the Committee on Resolutions.

The Chair announced Drs. Walter Kempster, Mark Ranney, and E. A. Kilbourne as a committee to prepare a memorial on the death of Dr. McDill.

EXPERT TESTIMONY.

Dr. Thomas F. Green, of the Lunatic Asylum, Milledgeville, Georgia, then made a few remarks on the value of expert testimony in cases where pleas of insanity are entered in court. He thought that all members of the medical and legal professions should take care to post themselves thoroughly on the subject of insanity.

USE OF CHLORAL.

The afternoon session being called to order, Dr. T. R. H. Smith, of Lunatic Asylum No. 1, Fulton, Mo., introduced the subject of the use of chloral, which he considered a highly important one. He thought much injury was done by the injudicious use of this drug, and regarded it as a remedy which ought to be used with the greatest care, and the results closely watched. He believed that frequently the results of the chloral were mistaken for the regular progress of the disease, and that sometimes it had caused death. In chronic doses of insanity he regarded chloral as a very unsafe remedy. Also in the cases of aged people.

Dr. George C. Catlett, of Lunatic Asylum No. 2., at St. Joseph, Missouri, said that he knew of three well-authenticated cases of death from the administration of ordinary doses of chloral as a sedative in cases of delirium from intemperance.

Dr. C. F. MacDonald, of the State Lunatic Asylum for Insane Criminals, at Auburn, N. Y., remarked that on an occasion an attendant gave a patient two drachms of chloral by mistake. The patient suffered from acute mania, and soon after taking the dose fell into a heavy sleep, and afterwards awoke calmer and quieter, and progressed to a complete recovery.

Dr. A. E. MacDonald, of the City Asylum for the Insane, at Ward's Island, New York, considered chloral a valuable remedy, and had used it a great deal in his practice. He had never heard of a death said to be from chloral, where the post-mortem examination did not reveal other causes for death.

Dr. Kirkbride said that his sad experience with chloral had been, that sometimes patients died unexpectedly to him, and he would not like his medical friends to administer it to him under any circumstances.

Dr. Wm. M. Compton, of the Lunatic Asylum, Jackson, Miss., said that there were several noisy patients in

his institution who had taken doses of from 20 to 30 grains of chloral every evening for years, merely to quiet them and produce sleep, and he had never seen any bad effects.

Dr. R. H. Smith moved the appointment of a committee to examine and report at the next meeting on the use of hydrate of chloral. Adopted.

The Chair appointed Drs. T. R. H. Smith, C. F. MacDonald, of Auburn, N. Y., and H. M. Harlow, of Augusta, Maine.

Dr. Orpheus Everts, of the Hospital for the Insane, Indianapolis, Ind., read a paper on "Incidents of Civilization as Predisposing and Exciting Causes of Mental Disorders."

Dr. A. E. MacDonald presented a series of resolutions condemning the crowded condition of the Philadelphia Almshouse, after which the Association adjourned.

The Association extended its sessions until the fifth day, when Mr. Francis Wells, of the State Board of Charities, in order to defend the State authorities against the charge of inadequate provision for the insane at the Almshouse, said that a large hospital capable of accommodating six or seven hundred had been provided for.

Dr. Kirkbride said that the State has made an appropriation of $25,000 to commence the work of providing for the insane in the Almshouse and in the seven adjoining counties. This was a perfect farce. The Pennsylvania State Medical Society, he said, had recommended a hospital for the surrounding counties, exclusive of Philadelphia—not because they did not want Philadelphia to have a hospital, but because it was folly to expect to provide for the insane of Philadelphia and seven adjoining counties in one hospital. Superintendents agreed that six hundred patients was the maximum number proper to be in a hospital, and there should at once be two hospitals built for Philadelphia for the accommodation of the twelve hundred unfortunates in the Almshouse.

After the transaction of some routine business the Association then adjourned *sine die*.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from June 18th to June 24th, 1876.

Head, J. F., Surgeon and Medical Director. Granted leave of absence for two months, and fifteen days, with permission to go beyond sea. S. O. 120, A. G. O. June 14, 1876.

McCormick, Chas., Surgeon. To proceed to New York city, and there await orders. S. O. 123, A. G. O., June 20, 1876.

Vollum, E. P., Surgeon. Assigned to duty at St. Louis Barracks, Mo. S. O. 121, A. G. O., June 16, 1876.

Clements, B. A., Surgeon. To report to the Commanding General Department of Dakota, for assignment to duty. S. O. 121, c. s., A. G. O.

Sternberg, Geo. M., Asst. Surgeon. Assigned temporarily to duty as Attending Surgeon at these Headquarters. S. O., 74, c. s., Department of the Columbia.

Horton, S. M., Asst. Surgeon. Granted leave of absence for four months. S. O., 123, c. s., A. G. O.

Woodhull, A. A., Asst. Surgeon. Leave of absence extended one month. S. O. 121, c. s., A. G. O.

Weisel, D., Assist. Surgeon. Assigned to duty at Fort Canby, W. T. S. O. 69, c. s., Department of the Columbia.

Bartholf, J. H., Asst. Surgeon. Granted leave of absence for two months to visit the Centennial Exhibition. S. O. 69, Department of the Columbia, June 3, 1876.

Cherbonnier, A. V., Medical Storekeeper. Granted leave of absence for one month. S. O. 123, c. s., A. G. O.

Medical Items and News.

Association of Superintendents of Institutions for Idiots.—A convention of the Superintendents of the Asylums for the Feeble-Minded of the United States, was held at the Pennsylvania Training School, June 6, 7, and 8, there being present Dr. H. B. Wilbur, of New York; Dr. G. A. Brown, of Barre, Mass.; Dr. Tuck, of Boston; Dr. Doren, of Columbus; C. T. Wilbur, of Illinois; Dr. Kerlin, of Media; Dr. Knight, of Connecticut, and Dr. E. Seguin, of this city. These gentlemen represented institutions containing 1,300 inmates, and their deliberations were such as looked to the extension of their good work in all of the States. The proportion of idiots and feeble-minded to population was the same as that of the insane; while extraordinary provision for the latter had been very properly made in nearly every State, but little had been done or thought of for the comfort and amelioration of weak-minded children and idiots, excepting as they were shut up with the insane, or sunk lower in our almshouses. The superintendents of this specialty have now organized themselves into an association, calling to their aid and counsel both men and women outside of their institutions, who have distinguished themselves by an interest in these afflicted persons, for whom a better era seems now to open. On Wednesday afternoon an interesting exhibition of the classes under training was given before the Convention and a Committee of the Board of Directors—Messrs. Ash, Martin, and Rogers. Addresses highly complimentary to teachers and children were made by Doctors Knight, Brown, and Parish, the two first named gentlemen asserting that our American institutions now surpass those of Europe in thoroughness of appointment and educational success. The officers chosen for the year are: President, Dr. E. Seguin, of New York; Vice-President, Dr. H. B. Wilbur, Syracuse, N. Y.; Secretary, Isaac N. Kerlin, Media, Pa.; and the next annual meeting will be held at the Asylum for the Feeble-Minded, Columbus, Ohio, June 5th, 1877.

Rhode Island State Medical Society.—The sixty-fifth annual meeting of the Rhode Island Medical Society was held in Franklin Lyceum Hall, Providence, June 14th, at ten o'clock; Dr. Geo. W. Jenckes, of Woonsocket, President, in the chair. The reports of the various standing committees were duly presented and adopted, after which delegates from other State medical organizations were received. The report of the Fiske prize fund showed a balance in the hands of the trustees of $1,242.64. The trustees made no award of premiums on the subjects offered for essay last year. For the best dissertations on the following subjects, or either of them, the trustees offered the premium of $200 for this year: *First*. What is the best means, civil, social, and medical, that can be used for the prevention of disease? *Second*. The causes and nature of cerebral disturbances, so frequently occurring, especially those following active mental exercise.

Dr. W. O. Brown stated that the State Board of

Pharmacy, which was chartered by the General Assembly, upon the petition of this Society, six years since, had become a very useful and successful institution, and should receive recognition and encouragement from the Society. The report of the Board of Pharmacy for 1876 showed there are eighty four registered pharmacists and thirty assistant pharmacists in the State, and expresses satisfaction with the successful and harmonious working of the law.

The Board of Censors nominated Drs. George L. Collins and James H. Eldridge for delegates to the International Medical Convention, to be held in Philadelphia, September 6th.

Dr. S. S. Keene was appointed Anniversary Chairman for next year.

The following officers were elected for the ensuing year:

President, Dr. Edwin M. Snow, Providence; *First Vice-President*, Dr. Charles H. Fisher, North Scituate; *Second Vice-President*, Dr. Edward T. Caswell, Providence; *Recording Secretary*, Dr. Walter E. Anthony, Providence; *Corresponding Secretary*, Dr. Edward M. Harris, Providence; *Treasurer*, Dr. Timothy Newell, Providence (Dr. F. H. Peckham, Jr., declining a re-election); *Board of Censors*, Drs. Ariel Ballou, James H. Eldridge, Geo. Baker, Otis Bullock, Sylvanus Clapp, Welcome O. Brown, David King, J. W. C. Ely; *Registration Committee*, Drs. E. M. Snow, E. T. Caswell, Jas. H. Eldridge; *Publication Committee*, Drs. C. O'Leary, W. O. Brown, H. G. Miller, C. T. Gardner; *Auditing Committee*, Drs. C. W. Parsons, C. W. Fabyan; *Dinner Committee*, Drs. T. Newell, A. E. Ham.

On motion, it was voted to hold the September quarterly meeting in Lyceum Hall.

The annual dinner took place at 2½ P.M., at the Horse Guards Armory, Dr. George L. Collins, of Providence, acting as toast-master. After a brief and happy address of welcome by Dr. Collins, the toasts were responded to in their regular order, the entertainment closing with a humorous poem by Dr. Virgil O. Hardon, of Providence.

Recent Changes in the Faculty of the Medical Department of the University of the City of New York.—Prof. Charles A. Budd has been made Emeritus Professor of Obstetrics, and will continue his clinics in Bellevue Hospital. Prof. Walter R. Gillette has resigned. Dr. Wright, former lecturer in the summer faculty, will deliver the course of lectures on obstetrics during the next winter session. Prof. Erskine Mason has resigned. Prof. Faneuil D. Weisse has been made Professor of Practical and Surgical Anatomy, and will have charge of the dissecting room. Prof. Witthaus has been made Adjunct to the Chair of Physiology and Physiological Chemistry. Dr. J. W. S. Gouley has been made Professor of Genito-Urinary Diseases.

Medical Society of the County of New York.—At a stated meeting of the New York County Medical Society, held June 26, 1876, Drs. Edward F. Walker, Mary Elizabeth Baldwin, and John A. Steiner, were elected members.

International Medical Congress at Philadelphia.—Delegates have been chosen as follows: By the Medical Society of London, England, William Adams (President), Drs. J. Langdon Dower and Richard Davy (Honorary Secretary). By the Medical Society of Copenhagen, Drs. Edmund Hansen (President), Carl Lange and S. Engelsted. By the Pathological Society of Dublin, Mr. Joliffe Tufnell and Prof. William Stokes. By the Waterloo County Medical Society of Canada, Drs. D. L. Walmsley, G. W. Bingham, T. W. Vardon, J. H. Webb, D. S. Bawlley, and J. P. Jackson. By the Medizinischer Verein, A. Greifswald, Prof. Hüter. By the Obstetrical Society of Edinburgh, Drs. Alexander R. Simpson (President) and Finlay. In all cases such delegates are chosen as express a desire or intention to be present. The following gentlemen, in addition to those previously mentioned, will also attend the Congress: Henry Power, of London, J. A. Estlander, of Helsingfors, Alfred Haviland, of London.

The Late Dr. John O. Stone.—At a stated meeting of the New York Academy of Medicine, held June 15th, 1876, a committee, consisting of Drs. A. C. Post, Oliver White, and G. M. Smith, presented the following preamble and resolutions, which were unanimously adopted:

Whereas, It has pleased Almighty God to call away from earth the soul of our late fellow, Dr. John O. Stone,

Resolved, That we have heard of the death of our late associate with sincere regret.

Resolved, That we cherish his memory as that of a learned and intelligent member of the medical profession, of an honest and upright man, and of a public-spirited citizen.

Resolved, That we sympathize with his family in the great bereavement which they have sustained.

Resolved, That a copy of these resolutions be sent to the family of the deceased, and to each of the medical journals of this city.

S. S. PURPLE, M.D., *President*.
W. T. White, M.D., *Secretary*.

Contagious Diseases.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending June 24, 1876.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.
June 17.....	0	4	58	0	28	50	11
June 24.....	0	8	36	3	29	49	17

University of Pennsylvania.—Dr. H. C. Wood was, on the 20th inst., elected by the Trustees of the University of Pennsylvania, Professor of Materia Medica, etc., in place of Prof. Joseph Carson, resigned. For the first time in many years in that city the appointment was made without a contest.

Dr. Walter R. Gillette has been appointed an Attending Physician to the New York Lying-in Asylum.

Rabies from Bite of a Non-rabid Dog.—Mr. Holcombe, Veterinary Surgeon of Plainfield, reports a case of rabies in a heifer which was bitten by a dog. The heifer died; the dog is alive and well, with the exception of a gun-shot wound received while running about in the field.

Hydrophobia.—A very extensive or serious outbreak of rabies, epizootic in its nature, has recently occurred in Bavaria. It is stated that about fifty persons have been bitten in a short time by mad dogs.

University of Leipsic.—The united salaries of the professors of the University of Leipsic amount to 87,000 marks, or $21,850 in gold.

Original Communications.

TWO CASES OF SEVERE COMPOUND FRACTURE, WITH REMARKS.*

By FREDERICK D. LENTE, M.D.,
SARATOGA SPRINGS, N. Y.

CASE I.—*Crushing of the Elbow-Joint. Recovery, with a useful Joint.*—M. OB., a young and healthy man, a workman in the West Point Foundry, sustained the above injury, on the 20th March, 1875, in consequence of the fall of a mould, weighing four tons and a half, upon the part, which was caught between the box and a hard pavement. Of course, all the tissues directly involved in the injury were crushed to a jelly. But, fortunately, the edge of the iron box seemed to have passed mainly through the centre of the joint, and it was so sharp that it cut through the bones like a chisel. Restricting the hemorrhage by means of Esmarch's bandage, and assisted by Dr. Murdock, I enlarged the wound and removed the detached fragments, consisting mainly of about half the head of the ulna, longitudinally chipped off, and a piece of the internal condyle of considerable size. The ulnar nerve lay completely bare in the wound for at least three inches, and had a bruised appearance. The limb was placed in an angular gutter of tin, and a vessel arranged to supply a constant small stream of water to some lint laid over the wound. At the end of two weeks the arm was put up in a plaster splint, with *fenestra* for allowing the exit of pus. At the end of five weeks from this date, the immovable apparatus was removed, and *a guttered splint was applied to the inner* aspect of the arm, and another to the forearm; and these were connected by Stromeyer's screw, which permitted the very slightest and most perfectly graduated motion of extension or flexion to be communicated to the joint by the patient himself, by turning one thread of the screw at a time. Thus motion, so slight as not to interfere at all with the union and cicatrization of the soft parts, could be used, and yet sufficient to prevent any false anchylosis. He first made only one turn of the screw a day; and, as the healing progressed, two; then three, etc. And when he thus got the arm extended, he proceeded, in like manner, to flex it. This apparatus was employed for nearly three months.

After the removal of this apparatus, he was directed to carry light weights, and use the hand as freely as possible. The sensation in the little and ring fingers was but slight; but there was no neuralgia, which was feared from the condition of the ulnar nerve.

In a letter dated December 21st, written to me while in Florida, he says: "I am gaining slowly but steadily; can carry a pail of water and place it on a table, and saw wood. But the motion at the wrist, which originates at the elbow (he means supination and pronation), is lost as yet. It is getting very strong." Dr. Murdock writes that he has now free motion, through an arc of about 120°. Has good and steadily increasing power in the biceps; no rotation of forearm. Has recovered sensation in the little and ring fingers perfectly.

CASE II.—*Compound fracture of surgical Neck of Humerus. Rapid Recovery, with a useful joint. Use of Plaster Splint.* This case is not reported because it is an extraordinary one, either as regards rarity or result, but partly to call the attention to the peculiar fitness of the plaster bandage, not only for this injury but for various other accidents which frequently occur at the shoulder-joint and vicinity, and which are of a peculiarly troublesome nature, and, not seldom, rebellious to treatment.

W. H. M., a young married man, a machinist by occupation, fell from a fruit tree on the 10th Sept., 1875, a distance of about fifteen feet, striking apparently on his left shoulder and elbow. He got up and walked into the house, being only stunned for a few moments. I found him, soon after, sitting on a sofa, with very little pain, and no evidence of shock. On opening his shirt I saw, with much surprise, about an inch or so of the fractured end of the humerus protruding through the skin. From the manner in which the soft parts were forced upwards by the blunt end of the bone, which was broken directly across, the opening appeared to be an inch or so only below the clavicle; but, on reduction, was found to be at the inner border of the deltoid, some distance below the clavicle.

Having secured the assistance of Dr. B. J. D. Erwin, the surgeon of the Military Academy at West Point, and aided by Dr. Goldthwaite of the house-staff of Bellevue Hospital, I sawed off an inch or so of the projecting bone, to facilitate reduction, and also to prevent subsequent overriding of the fragments; reduction was thus easily effected. Having then removed some small fragments at considerable depth, by twisting them out with the forceps, the arm, forearm, and hand were placed in a tin gutter. The liability of the parts adjacent to the wound to become excoriated by the discharge lodging between them was foreseen and provided for, as far as possible, by directing constant watchfulness on the part of the attendants.

Sept. 12th.—Has had but little pain, and, with the aid of mild anodynes, has rested pretty well.

On the fourth day, 13th, there was much discoloration and tumefaction, extending, more or less distinctly, from the root of the neck, over the shoulder and scapula, and down the side to the lower border of the ribs, and the temperature was 104°. The discharge was of the ordinary purulo-sanguinolent character of this period of the injury, and already excoriating the integuments of the axilla. The tin splint proving uncomfortably heavy on the chest and abdomen, it was removed, and the forearm placed in a sling, with a few turns of bandage around the arm and body; his extreme care in changing his position obviating any danger of injurious motion at the seat of fracture. This was a great relief. Patent oakum was stuffed into the axilla to catch the discharge, and frequently changed. A thick cataplasm was applied over all the swollen parts, from the neck to the hip. Under it, the trouble rapidly subsided, and it was gradually reduced in size and thickness.

On the 4th October the patient had been progressing very favorably; appetite and spirits good, sleeping well without anodynes, but never able to assume the recumbent posture completely, on account of motion communicated to the fracture by the attempt. At this date applied the plaster bandage, using the rollers rubbed in dry plaster as usual. The whole arm and forearm, to the wrist, including the left shoulder, was secured solidly to the body. Extra layers were carried from the median line behind, over the shoulder, the outer aspect of arm, and ulnar border of fore-arm. During the setting process the end of the bone was kept pressed firmly against the head, to secure it in complete apposition. From the time the splint be-

* These cases were verbally reported at a meeting of the "Georgia Medical Society," at Savannah, in Dec., 1875.

came solid and hard, the patient experienced complete relief, and could lie down without difficulty, and required no further attendance. I did not see him again, having moved from Cold Spring in the meantime, until he met me by appointment, between six and seven weeks after, at Prof. Darby's clinic in the University of the City of New York, where I removed the apparatus, at his request, in the presence of the class. It was removed like a cuirass, in such a manner that it might easily have been reapplied, if necessary, by a few turns of roller to secure it. But it was unnecessary, as the union was found to be complete, and the patient already had tolerably free motion at joint. There was some stiffness at the elbow, for which passive motion was enjoined.

In February the patient came to Florida to put up some machinery, having recovered sufficient use of his arm to attend to business, and visited me at Palatka, where I had an opportunity to examine his arm again. The motion of the arm was restricted somewhat by weakness of the muscles, especially the deltoid, which is very apt to suffer, and sometimes to atrophy, from blows about the shoulder, and he was advised to use electricity. He did so, and now he informs me that he has derived decided benefit.

It is my belief that a *cuirass* bandage like this would form a much more effectual and comfortable treatment than any now in use for various other injuries in the vicinity of the shoulder; for fracture of the *neck of the scapula;* for dislocation of the *outer end of the clavicle;* for any fracture in the *upper fourth of the humerus:* for fracture *near the middle* of the clavicle, where there is a decided tendency to displacement, and where all apparatus frequently fails to keep the fragments in anything like perfect apposition, and particularly if any of these injuries be complicated by *delirium tremens*, or by *insanity*, or the patient should require removal by rail or carriage. No matter how heavy the apparatus may seem, it is comfortably borne, because the weight is so evenly distributed. As regards one at least of these injuries, dislocation of the acromial end of the clavicle, surgical writers have generally agreed as to the exceeding difficulty, if not impossibility, of maintaining the parts in perfect coaptation by any apparatus. The above bandage *must maintain* the parts in just the position in which they are held while the plaster is setting. Prof. Montgomery, of Buffalo, published a paper in the *Am. Journ. of Med. Sci.* for Oct., 1875, in which he maintains that Prof. Moore's cravat bandage for fractured clavicle is competent to retain a dislocated clavicle permanently in place. He gives instances from his own practice and that of others. I have used this simple and very ingenious contrivance for fractures, and like it very much, but should hardly expect so much from it in the other forms of injury as is claimed by Dr. Montgomery. Admitting that it has secured a perfect result in certain cases, nevertheless a slipping to a certain extent, or stretching, especially in the case of restless children or delirious adults, is very apt to occur, which, with the other apparatus, is impossible.

SARATOGA SPRINGS, June to Sept., 1875.

THE BOYLSTON MEDICAL PRIZES.—The Committee has announced the award of a prize of three hundred dollars to Dr. G. Gill Wylie, of New York, for a dissertation on "Civil Hospital Construction," and a prize of two hundred dollars to Dr. Mary Putnam-Jacobi, of New York, for a dissertation on the subject "Do Women require Mental and Bodily rest during Menstruation?"

STONE IN THE BLADDER,

ITS SPONTANEOUS EXPULSION AND ITS REMOVAL BY LITHOTRIPSY, LITHOTOMY, AND PERINEAL-LITHOTRITY, WITH AN ANALYSIS OF THIRTY-FIVE CASES; BEING AN ABSTRACT OF A PAPER READ TO THE MEDICAL SOCIETY OF THE STATE OF NEW YORK, JUNE, 1876.

BY J. W. S. GOULEY, M.D.,

PROFESSOR OF DISEASES OF THE GENITO-URINARY SYSTEM IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF NEW YORK, SURGEON TO BELLEVUE HOSPITAL, ETC.

AN abstract only of the paper is here given, owing to its length, and because it will appear in full elsewhere. It contains a brief account of the genesis of vesical stones, of the treatment of nephretic colic, of the use of alkalies and other remedies in expediting the spontaneous expulsion of small calculi from the ureters and from the bladder, of the early detection of stone, and of the instruments best adapted to the purpose.

The writer considers that the time has arrived for lithotripsy to be adopted as the general operation in adult males whose urethræ are normal or can be rendered so practically; for lithotomy to be resorted to only in cases accompanied by narrow and undilatable urethral strictures, or by cystitis with uncontrollable vesical irritability, and in young children; and for perineal-lithotrity and its modifications to be reserved for cases of large stones.

A succinct account of these various modes of treatment of stone in the bladder is followed by a report of thirty-five cases, an analysis of which is here given.

The thirty-five patients suffering from vesical calculi who had come under treatment, ranged from two to seventy-four years of age.

In seven cases the stones were expelled spontaneously from the bladder.

Thirteen cases were subjected to lithotripsy.

Ten cases underwent lithotomy, and in five cases perineal-lithotrity was done. Thirty-three recovered and two died.

The seven patients whose calculi were expelled from the bladder were from twenty-five to sixty-two years of age.

They had all had from one to four attacks of nephretic colic, and five had already expelled calculi per urethram.

Two had urethral strictures; in one of these two calculi were impacted behind a stricture which had to be dilated before they could be extracted.

Two had prostatic hypertrophy, but the stones were finally expelled.

In one case the calculi were very small but numerous.

In one case there were ten calculi, the size of buckshot.

In one case there were four, one of which was equal in diameter to No. 15 sound, and weighed ten grains.

In one case there were two, both of which became impacted behind a urethral stricture, and were extracted with dressing forceps.

There was one in each of the three remaining cases, and in one of these cases the stone weighed ten grains.

The calculi were all of uric acid, and were expelled from the bladder in from one to thirty days or more after the nephretic colic.

The treatment consisted in the use of diluents and alkalies, cathartics, dilatation of the urethra, etc.

All the patients made good recoveries.

The thirteen patients subjected to lithotripsy were between the ages of 24 and 66; three were under 30; three were from 34 to 37; three from 48 to 60, and four from 62 to 66.

Eight of the thirteen had troublesome cystitis, with much vesical and urethral sensitiveness, which required prolonged treatment before the operation could be done.

Three had urethral strictures, which, however, yielded to gradual dilatation before the operation.

In five cases it was necessary to enlarge the meatus urinarius by incision.

Four cases were complicated with prostatic enlargement.

Two cases had before undergone lithotomy.

Two cases had already been lithotriptized.

The stone was small in two cases; of medium size in five cases, and exceeded one inch in diameter in four cases.

There were several stones in one case; four in one case; two exceeding one inch in diameter in one case, and one stone in each of the ten remaining cases.

Every case underwent the most careful preparatory treatment.

Four cases were cured in one sitting; one in three sittings; one in four sittings; four cases in five sittings each; one case in seven sittings, and one in twenty-four sittings.

One case was followed by a rigor after the first sitting; one case after each of the four sittings; while the remainder had no rigors at all.

In one single case did any of the sittings exceed five minutes, and that by one minute only. In most of the cases the sittings were of from one and a half to three minutes' duration.

The lithotrite was introduced twice in one sitting in three cases. In all the others the instrument remained in the bladder until from three to fifteen crushings had been made, when it was withdrawn not to be again used until the next sitting.

The intervals of time between the sittings varied from two to eight days, except in two cases, where they were extended to several months at the request of patients.

In no case did orchitis supervene.

No sitting has been followed by severe hemorrhage, and only in some of the patients of sixty and upwards has the urine been tinged with blood. Even in these cases the urine became clear within twenty-four hours.

No sitting has been followed by severe cystitis, on the contrary, after the second sitting the vesical irritability has usually so diminished as to render the subsequent sittings easy for the patient and for the operator.

Expulsion of detritus from the beak of the lithotrite was always effected to a sufficient extent to permit closure of the jaws, so that the urethra sustained no injury in any case during the withdrawal of the instrument. The detritus was spontaneously expelled with the urine in ten cases. Aspiration of the fragments was made in one case. In one case aspiration was used only during one sitting, the detritus having been expelled spontaneously afterwards. In one case all the detritus was removed by the lithotrite and by an evacuating catheter, as none could be expelled on account of vesical atony. Impaction of fragments in the urethra occurred in five cases, but caused little inconvenience in any case, as they were either very soon expelled or forthwith extracted. The amount of detritus gathered varied from a few grains to an ounce and a quarter. The most rigid after-treatment was enjoined in each case.

There has been no recurrence of the trouble in any case except one, in which calculi were periodically escaping from the ureters. This was the fatal case. One patient died, and the cause of his death was pyelonephritis, both kidneys and ureters being filled with small calculi. The operation had to be discontinued twice on account of the renal trouble, and death occurred about eight weeks after the suspension of the treatment.

Of the ten patients upon whom lithotomy was performed, one was twenty-four years old, and the others were all under ten years of age. The eldest of these was eight years, the youngest two years of age.

Three patients had troublesome cystitis.

One had urethral stricture.

The stone was large in one case, in the others it was of medium size and small.

There were three stones in one case; two in another, and one in each of the remaining eight cases.

Lateral perineal cystotomy was done in five cases.

Lateral section of the anterior half of the prostate, with cystectasy, was done in three cases.

The median operation was performed in two cases.

Fragmentation of the stone was necessary, before extraction could be accomplished, in one case, and in this lateral perineal cystotomy was done. Extraction was not attended with difficulty in any of the other cases.

There was no serious hemorrhage in any case.

The urine was passed at will, from the day of the operation, in four cases.

The urine flowed entirely through the urethra, from the eleventh day after the operation, in one case; from the eighth day in one case; from the fourth day in one case; time not stated in five cases.

In two cases all the urine, from the time of the operation, was passed at will and through the urethra, not a drop escaping by the wound. The wound was healed in twenty-eight days in one case; in twenty days in two cases; in fourteen days in three cases; in ten days in two cases; in seven days in one case; and the date of union of the wound was not stated in one case.

In one case a fistula still exists, through which a few drops of urine escape.

All the patients recovered.

Of the five patients subjected to perineal-lithotrity, one was seventeen, one thirty-seven, one sixty, one seventy-four, and one fifty two years of age. One had been lithotomized seven years before. They had all long been distressed with cystitis. In one case there were two stones, the four others had only one calculus each. In one case the nucleus of the stone was a piece of glass.

In all the cases the stones were large, the detritus weighing in Case I., twelve hundred grains; in Case II., four hundred and eighty grains; in Case III., two hundred and seventy grains; in Case IV., nine hundred and sixty grains; in Case V., four hundred and nine grains. They consisted all mainly of phosphates.

The perineal incision was made freer than usual, and the bulb of the urethra had to be divided for nearly its whole length in one case. (Case I.)

In two cases the incision was made in accordance with Dolbeau's directions, and the membranous portion of the urethra only was divided.

In two cases the bistoury was plunged, cutting edge upwards, into the median line of the perinæum, close to the anal margin, until its point entered the groove of the staff, and nearly the whole membranous portion of the urethra cut longitudinally from behind

forward, and the cutaneous incision was completed at one sweep in withdrawing the knife.

In one case, dilatation of the prostatic urethra and neck of the bladder was made partly with a two-bladed dilator, partly with the finger. Dolbeau's six-branched dilator was used in three cases, and the hydraulic dilator in one case.

Fragmentation was made partly with a fenestrated lithotrite, introduced through the normal route, partly with strong forceps passed through the artificial opening, in two cases. Dolbeau's and my own lithoclasts were used in the others.

The stone was hard in one case, and soft in four cases.

Exploration, as recommended by Dolbeau, with small lithotomy forceps, was made in all the cases, and in three instances the stone, being once seized, could not without difficulty, and twice not without considerable delay, be disengaged from the forceps.

Extraction of the detritus was, in all the cases, effected with the lithoclasts, with lithotomy forceps, and with the scoop.

In all the cases frequent vesical injections of cold water had the happy effect of bringing within reach large and small fragments, after the bladder had seemed free from calculous matter.

Contrary to Dolbeau's directions, the finger was a number of times introduced into the bladder, in every case without giving rise to the least untoward symptom.

The loss of blood did not exceed four ounces in any case.

In one case the urine was passed at will from the day of the operation; in one case within twenty-four hours thereafter, and in one case in forty-eight hours. In one case the urine dribbled from the wound for two weeks. In the fatal case the urine also dribbled from the wound, very little occasionally passing through the normal route.

The wound healed in two weeks in two cases. A perineal fistula was established as a precautionary measure against cystitis in one case.

Four patients recovered and one died in a week of pyæmia.

Progress of Medical Science.

Empyema and Thoracentesis.—In answer to a series of questions as to the treatment, causes, and sequelæ of empyema, Dr. Bowditch, of Boston, states that, although he cannot give the percentage of recoveries in his practice, he has up to this time performed thoracentesis 328 times, on 207 patients, and that none of his patients have died immediately, or in consequence of the operation. He explains the large number of deaths after the operation, in Europe, by the desire of the operators to do too much, and thus prolong the operation beyond the time proper for the patient. They desire to get out all the fluid that can be drawn. His own rule is to stop suction the moment the patient begins to suffer from *any uncomfortable* symptoms—stricture of the chest, severe harassing cough, etc. A mild cough is a favorable sign, as it indicates expansion of the lungs. This rule applies to all cases, whether serum, pus, bloody or fœtid fluid be found in the pleural cavity.

Dr. Bowditch asserts that nearly all children with empyema recover after thoracentesis. Adults with recent trouble are in a more favorable condition for recovery than when the disease is chronic. Sometimes after repeated operations phthisis is liable to set in. In such a case the repeating of the aspiration is a bad mode of proceeding. It is better, if after aspirating once, or at most, twice, a constant tendency to the re-accumulation of pus is found, to make a free and permanent opening. This may be made by means of a trocar and canula just large enough to admit the passage of a drainage-tube. Shorter canulas must be substituted for the one originally used, according as the cavity diminishes in size. A free incision is more painful, but is the better operation of the two. With regard to the subsequent treatment, as long as laudable pus is being thrown out, and the lung is expanding, and the patient is improving, Dr. Bowditch does nothing. He thinks that patients are often made worse by too much "washing out the cavity." If, however, the patient fails, has hectic, etc., he uses injections of warm water, which often produce the happiest results. He has not used carbolic acid, but thinks that it may be useful. Constant drainage is his rule. Where the fluid drawn is serous he prefers repeated aspiration to a permanent opening. If the serum be bloody at the first operation he never makes a permanent opening, for the case is then one of malignant disease. Empyema may occur in persons previously healthy; but a bad constitution is often at the bottom of the matter. As sequelæ, Dr. Bowditch has never met with Bright's disease or enlarged liver, but has met with tuberculosis and enlargement of the heart in a few cases. In these last cases, though the fluid did not re-accumulate, the lung never regained its free expansion, and after months of trouble the patients died suddenly with cardiac symptoms.—*Cincinnati Lancet and Observer*, June, 1876.

Transfusion of Blood.—Assistant-Surgeon Wood, U. S. A., reports a successful case of transfusion of defibrinated human blood in a case of tubercular phthisis. The patient was reduced to the last stages of exhaustion and emaciation, and it seemed evident that he could not live forty-eight hours longer. Nearly four ounces of blood were injected, when the patient complained of a sense of fulness in the head, and the operation was stopped. Just before the operation his temperature was 102⅘° F., pulse 105, respiration 34, and he was orthopnœic, and in great distress. Before two ounces of blood had been injected he felt relieved, and shortly after the operation his temperature was 101⅗° F., pulse 101, respiration 27; he was breathing more easily, felt quite comfortable, and his eyes, ears, and nose had assumed a healthier hue. The night-sweats, which had resisted all measures for their relief, disappeared on the third night after the transfusion, and the hæmoptysis, which had been very frequent, ceased entirely. He began at once to gain appetite, strength, and flesh. In less than a month he gained seventeen pounds in weight, and is increasing in weight at the rate of three-quarters of a pound daily. The dyspnœa is now insignificant, and the destruction of lung tissue seems to have been arrested.

The operation was one of remarkable simplicity. Seven ounces of venous blood were drawn from a man's arm into a mortar that was placed in a water bath and raised to a temperature of 105° F., after which the apparatus was allowed to cool down to 100° F., at which temperature it was kept during the operation. The blood was carefully defibrinated by a wisp of broom, and afterwards constantly stirred. The left median cephalic vein of the patient was then

exposed, and three ligatures placed around it, the distal one to prevent hemorrhage, the proximal one to prevent the entrance of air, and the middle one to grasp the nozzle of the syringe. A valvular incision was now made in the vein between the distal and median ligatures. A common hard rubber syringe was filled with the blood, its point introduced into the vein nearly to the proximal ligature, and enough of its contents forced out to deprive this portion of the vein of any air it might contain. The middle ligature was then tightened about the nozzle of the syringe, the proximal ligature was loosened, and the syringe emptied. The proximal ligature was now again tightened, the middle one loosened, and the syringe withdrawn to be refilled with blood. This process was repeated until nearly four ounces of blood had been injected. There were no troublesome symptoms after the operation, no phlebitis, no rigors, and no aggravation of the dyspnœa. The great beauty of this operation lies in its simplicity, no special or complicated apparatus being required for it.—*Chicago Medical Journal and Examiner*, June, 1876.

Foreign Bodies in the Air Passages.—Prof. Hamilton, of the Columbus Medical College, contributes a valuable paper to the first number of the *Ohio Medical Recorder*, in which he puts on record twenty-one cases of foreign bodies in the air passages. He divides his cases into three groups. The first group comprises four cases. In one, part of a grain of wheat was drawn into the air passages; in one a piece of privet leaf, and in two, bits of peanut shells, and in all four cases the foreign body was removed in a coughing fit. These cases emphasize the following point, viz., when the foreign body is known to be quite small or soft, flat and irregular, so that it is susceptible of being further softened, and enveloped by the viscid secretion of the air passages, it is so slightly irritating, and so well adapted for spontaneous expulsion, that an operation is inadmissible.

The second group comprises two cases, in which the body was irregular, and its movements and relations could not be well estimated. In one case, the patient, a child, died suddenly with croupal symptoms, and a piece of a hickory nut shell was found in the larynx at the post-mortem. In the other a pregnant woman inhaled a shirt button with a pin stuck in it. No marked symptoms were excited, and, after a few weeks, the button was coughed up, followed, after a few months by the pin.

The third group includes fifteen cases. In all of them the foreign body was hard, smooth, and round in outline; in one it was a grain of pop-corn in its natural state; in one a locust seed; in three a large full bean; in three a water-melon seed; in six a grain of common field corn, all dry and hard, except one, which was a grain of roasted green corn. In three of these cases no operation was performed; one of these patients died of broncho pneumonia in seven days, and the other two coughed up the foreign bodies after several weeks, and recovered. In the remaining twelve patients there were thirteen operations, the foreign body being found in most cases at rest in the right bronchus, never fairly in the left. In six cases the body was expelled at once, and in the rest within from one to seventy-two hours. Where the body remains without motion in the bronchus after the operation, Prof. Hamilton advises that the patient be kept within reach, for sooner or later some movement will put it in motion, and then on simply dilating the opening expulsion will take place. One case died of broncho-pneumonia which had existed before the operation. In three cases laryngo-tracheotomy was performed, followed by impairment of voice in two, and the same result followed one of the tracheotomies. The patients were all under seven years of age, and the foreign bodies had been in the air passages from two hours to ninety six days.

On adding these fifteen cases to a number of cases tabulated by Dr. Weist, of Richmond, in which the foreign bodies were similar to those in our third group, we find that out of forty-five cases treated without operation, fourteen, or thirty-one per cent., died, while out of forty-six treated by operation, twelve, or twenty-six per cent., died; a difference of five per cent. in favor of the operation. These figures prove the incorrectness of the opinions so widely spread among medical men that foreign bodies in the air passages absolutely demand operation, and that the cases are of such emergency as to preclude sending a long distance for competent surgical aid.

Prof. Hamilton, for obvious reasons, opens the trachea above the isthmus of the thyroid gland, and divides usually four of the tracheal rings. Where this cannot be done without injuring the isthmus, he divides the cricoid cartilage and part of the crycothyroid membrane, which, however, is almost necessarily followed by impairment of voice.—*Ohio Medical Recorder*, June, 1876.

Chloral as an External Application.—The disinfecting properties of chloral are often utilized in the treatment of wounds, or of cavities containing fluids that have a fetid odor. M. Sivedey adds to it tincture of eucalyptus, in the following proportions:

℞ Tincturæ eucalypti.
Chloral hydrat.....ãã ʒ i.
Aquæ.....Oi.

This solution is very useful when employed daily as an injection in cases of empyema, of cysts that have been punctured, and in all other analogous cases.—*Journal de Méd. et de Chir.*, May, 1876.

Excision of the Knee and Amputation of the Thigh for Disease of the Knee-Joint.—At the last meeting of the Philadelphia College of Physicians, Dr. John Ashurst read a most interesting and valuable paper on the above subject. The paper began with the histories of ten cases of excision and five of amputation, all performed by Dr. Ashhurst himself. Excision was performed three times for arthritis with partial anchylosis, twice for arthritis with abscess, once for arthritis following small-pox, and four times for gelatinous arthritis. Nine of these cases have recovered with useful limbs, one however still wearing a splint, as the operation was but recently performed, and the tenth case is convalescent and promises to have as favorable a result as the other nine. Amputation of the thigh was performed in five cases that did not admit of excision on account of the extent of the disease or of visceral complications. One of these cases only proved fatal. This patient was fifty one years of age, and a man of intemperate habits; and the operation was performed for acute destructive inflammation of the knee-joint following an injury to the leg. In all the other fourteen cases the arthritis was chronic, and the patients were between five and eighteen years of age.

After concluding the account of this remarkable series of cases, Dr. Ashhurst put his remarks in the form of answers to the following questions:

I. When should the surgeon abandon expectant measures in the treatment of knee-joint disease, and what may be considered the indications for a resort to operation?

II. Operative interference having been resolved upon, how shall the surgeon decide between excision and amputation?

III. When an attempt is made to save the limb by excision, how shall the operation be performed, and what shall be the after-treatment?

I. In answer to the first question it must be premised that most cases of inflammation, even of the larger joints, dependent on blows, sprains, or internal causes, are amenable in the early stages to treatment by rest and extension. Unfortunately, however, the case often appears at first so trivial that it is neglected until it is too late for the above treatment to be efficacious. Of the ten cases of excision reported above, in only one had the disease lasted less than one year, the duration ranging in the other cases from one to six years. Dr. Ashhurst does not deny that some of these cases might ultimately have got well without an operation, but the limbs secured by the operation were immeasurably better and more useful than the withered and deformed limbs resulting from the so-called spontaneous cures. In deciding on the propriety of an operation in any particular case, the age and general condition of the patient, and the duration and stage of the affection, must be considered. Excision of the knee is not very successful in children under five years of age: these suffer more from the confinement than older children, and, Dr. Ashhurst thinks, are also more liable to the insidious development of tuberculous and other constitutional diseases. In persons past the prime of life excision of the knee is so fatal, that it should be entirely discarded, and amputation resorted to where an operation is absolutely indicated. The most favorable age for excision is from five years to puberty.

The presence of visceral disease, as a rule, positively contra-indicates excision. An operation is seldom required in recent cases, in which rest, extension, and proper constitutional and local treatment will usually effect a cure. Dr. Ashhust maintains that these chronic joint affections, though unquestionably local diseases, are not of exclusively local origin, and that they require constitutional as well as local treatment. Finally, no operation should be performed as long as the disease is confined to the synorial membrane, or, even when all the tissues of the joint are involved, as long as the integrity of the part is maintained and a hope of preserving a useful joint remains. "But when the relaxed condition of the joint and the occurrence of consecutive dislocation show that the crucial ligaments and semilunar cartilages have disappeared; when the limb is contracted and helpless, and the patient gives a history of repeated relapses from comparatively slight injuries; or, on the other hand, when the doughy semi-elastic character of the swelling shows the existence of gelatinous arthritis (the typical 'white swelling' of the older writers), an operation may be properly resorted to, even if the limb be at the time in a quiet condition. When in addition the joint is in a state of suppuration, and still more if there be caries of the articular surfaces, an operation may be considered (other things being favorable) as almost imperative." The operation may be performed comparatively early in cases of gelatinous arthritis in which there is hardly any tendency to spontaneous recovery.

II. Amputation should be performed in preference to excision when the patient is too young or too old, when there are visceral complications, when the disease is too extensive to allow of its entire removal without taking away so much bone as would materially impair the usefulness of the limb, and when the question of the time required for recovery is important.

III. In performing the operation of excision, Dr. Ashhurst prefers the transverse incision across the front of the joint, just below the patella. He dissects back the skin and superficial fascia to the level at which he means to use the saw, then cuts directly down to the bone, and removes condyles, patella, and the diseased tissues together. The bones are divided from below upward by means of a Butcher's saw with blade reversed. The femur, in order to retain the natural inclination of the limb, should be sawn in a plane which as regards the axis of the femur is oblique from behind forwards, and from within outwards. The tibia should be sawn in a plane transverse to its long axis, with a slight antero-posterior obliquity. The epiphyseal junctions should not be interfered with in children; it is sufficient to remove a slice half an inch to an inch thick from the condyles, and less from the tibia. Any shreds of disorganized tissue may be cut away, but the floor of the wound must be left intact. The patella should always be removed. Tenotomy of the hamstring muscels may be necessary before the limb can be brought into position. Before the patient emerges from the anæsthesia, a posterior splint, bracketed opposite the knee, to allow of daily dressing of the wound, should be applied, and left undisturbed for at least a fortnight, and better still for six weeks, at the end of which time the process of bony union will be well advanced. A straight position is the best for the limb, on account of the shortening produced by the operation.

"Bruit de Galop" in Bright's Disease.—There is at present in the wards of M. Siredey, at the *Hôpital Lariboisière*, a patient who when admitted was suffering from an almost complete paralysis of the left arm and leg. Auscultation revealed a well marked "bruit de galop" at the apex of the heart. The urine was clear and abundant, but contained a large quantity of albumen. The diagnosis was Bright's disease, with interstitial nephritis. The point of greatest interest in this case was the auscultatory sign, which had first pointed to the true diagnosis. The two normal heart sounds preserved their ordinary characters, while the abnormal sound preceded the first sound by a very slight interval. In character it was much duller than the first sound of the heart; it was a shock, a sensible impulse, and could hardly be called a sound at all; it was felt rather than heard when the ear was laid on the patient's chest. It was perceived most distinctly in this case just above and to the right of the apex of the heart, but it can sometimes be heard over the entire præcordial region. Added to the two normal sounds, this one constitutes the peculiar rhythm to which the name "bruit de galop" has been applied. M. Potain has ascertained that it has been associated in all the cases reported as yet with the interstitial form of Bright's disease, coinciding with the cardiac hypertrophy that is so often present in that disease. In one case, however, it was present though there was no hypertrophy. In interstitial nephritis, moreover, we meet with lesions of the arterioles, as well as of the aorta and larger arteries,—lesions which affect seriously the circulation, and have probably some influence in producing the "bruit de galop."

As a diagnostic sign of an obscure kidney disease this bruit may attain great importance. Interstitial nephritis is often very slow and insidious in its evolution, exciting none of those symptoms that mark out so clearly the course of a catarrhal nephritis. The patient may be quite well, or may complain only of some vague and slight symptoms, until a sudden attack of dyspnœa, or palpitation, or a pulmonary or

cerebral hemorrhage occurs, without any apparent cause. M Potain has several times diagnosticated this condition of the kidney early in its course from the presence of the "bruit de galop," and if we have reason to hope that as we can recognize the kidney disease and its accompanying cardiac hypertrophy so early, we may also be able to arrest their progress by appropriate treatment. In one of M. Potain's cases, that was already far advanced, a notable improvement was brought about by the use of cups to the lumbar regions, derivatives, purgatives, and a milk diet. The albumen disappeared from the urine, the "bruit de galop" gradually disappeared, and the hypertrophy of the heart diminished, until its volume was little larger than normal.—*Journal de Méd. et de Chir.*, May, 1876.

A Case of Purpura; Death from Cerebral Hemorrhage.—On the 24th of last March, a shoemaker, aged 19 years, entered Hebra's wards, in the general hospital at Vienna. Three days before he had noticed some red spots, which soon became bluish and then brown, on his cheeks and breast. These spots increased rapidly in number, and on his admission they were abundant on the thorax and extremities, individually of small size, and did not disappear on pressure. The gums were pale, presenting but a few ecchymoses, but were not swollen. The urine was dark colored, and contained albumen and a large number of red globules. The patient stated that he had always lived under good hygienic conditions, and complained only of a slight degree of prostration. Two days passed without any change, out on the morning of the 27th his articulation became embarrassed, and soon after paralysis of the right side of the face and the right arm set in. In the evening he vomited a good deal, and after some hours of quiet sleep he fell into a state of colapse, which lasted until his death, at six A.M. on the 28th of March.

At the autopsy, a clot the size of a walnut was found in the anterior lobe of the left hemisphere of the brain. Microscopical examination revealed a pretty marked fatty degeneration of the arterial tunics of the vessels of the part, and a similar alteration of the capillaries in different parts of the encephalon. The serous membranes, especially the peritoneum, were sown with ecchymotic spots, some as large as the palm of the hand. The heart, muscles, and subcutaneous cellular tissue presented likewise numerous ecchymoses. The mucous membrane of the stomach was swollen and infiltrated with blood, and its epithelium was cloudy. The liver presented yellow spots here and there, and was also fatty; the renal epithelium, the muscles, and the heart were in the same condition. The blood was not coagulated, and the white corpuscles were increased in number, and were granular and fatty.

This case formed the subject of an interesting discussion at the Vienna Medical Society, in the course of which Professor Heschl asserted that it was a case of phosphorus poisoning. Professor Hebra reminded him that the chemical examination of the stomach and its contents, by Professor Hoffmann, failed to reveal the presence of free phosphorus or of phosphoric acid, and that there was nothing in the antecedents of the patient to support the theory of suicide or of a criminal poisoning. M. Lereboullet, in reviewing this discussion, points out, moreover, that the symptoms were not those of phosphorus poisoning. Cerebral hemorrhage may be the consequence of phosphorus poisoning, but it is only exceptionally so, while, on the other hand, it has been frequently met with in fatal cases of purpura, many of which are to be found in French medical literature. A case reported by M. Boucher, in 1867, presented not only a large hemorrhagic effusion into the left middle lobe of the brain, but also degeneration, fibroid and fatty, of the walls of the vessels, a steatosis of the liver, and marked alterations in the kidneys. M. Lereboullet concludes, then, that Prof. Hebra's case must be classed as one of purpura hemorrhagica, which, however, he admits to be an unsatisfactory term, as it designates only an assemblage of symptoms and not a disease as an entity.—*Gazette Hebdom.*, May 12, 1876.

Croton Chloral Hydrate as an Anæsthetic.—At the meeting of the *Société de Biologie*, on the 6th of May, M. Chouppe communicated the results of his experiments with croton chloral as an anæsthetic, and summed up as follows:

1. The hydrate of croton-chloral, when administered by intravenous injections, produces anæsthetic sleep much more rapidly and in smaller doses than the hydrate of chloral. As far as the effects of two substances can be compared on two different individuals, fifteen grains of croton-chloral produce the same anæsthetic effect as forty-five grains of chloral.

2. The anæsthesia is as profound as that produced by chloral.

3. The intravenous injections of croton chloral seem to be less dangerous immediately than those of chloral, but M. Chouppe could not yet speak of the ulterior effects.

Mr. Trasbot stated that he had often found pulmonary hemmorhages in horses after intravenous injections of chloral or of chloroform. Mr. Galippe called attention to a recent statement of Liebreich's that chloral produces anæsthesia of the head before the rest of the body, and that it is always more marked there.—*Gazette Hebdomadaire*, May 12.

Vaginal Urethrocele.—In the number of *The Lancet* for October 30th, Mr. Lawson Tait published the history of an interesting case of sacenlar dilatation of the urethra, and also an account of an operation that resulted in permanent cure. In concluding, Mr. Tait remarked that he knew of no parallel case being on record. M. Gillette, of Paris, however, claims that he described a similar case under the name of "urethrocele vaginale," in 1873, which case is reported at length in *The Lancet* of May 6th. The patient, a previously healthy woman, began about two months after her third confinement to suffer from some uneasiness and burning in micturition, and a slight sensation of weight in the region of the vulva. Soon afterwards she noticed that after each act of micturition, especially when she was obliged to retain the erect position, there would be an involuntary discharge of a small quantity of urine, which, however, was not attended by the burning pain that accompanied the voluntary discharge. This discharge took place also during the sexual act. Vaginal examination revealed an ovoid tumor (bosselure) about one and a half inches long by one inch wide, projecting into the vagina just behind the urinary meatus. Pressure on the tumor caused the escape of some urine from the meatus, and a female catheter introduced into the urethra was arrested in a cavity, and its point could be readily felt through the walls of the vagina. On pressing it onwards it entered the bladder, which presented no displacement. In compliance with the urgent desire of the patient a surgical operation was undertaken for the relief of the incontinence. A triangular piece of the mucous membrane of the anterior wall of the vagina was dissected out, the urethra being avoided, and the lips of the in-

cision were then brought together by the continuous suture. The operation has relieved the patient entirely of her distressing symptoms, but it is of course as yet uncertain whether the cure will be permanent.

In commenting on this communication, Mr. Tait, while admitting its value as a contribution to our knowledge of urethral diseases in the female, denies that the case is "very similar" to his own. The clinical features of the two cases are very different, and in his case the tumor, which was the size of an egg, could not be described by the word "bosselure." This tumor communicated with the urethra by a very small opening, only large enough to admit a No. 9 or 10 catheter, while from the above description it is probable that in Mr. Gillette's case there was general dilatation of the coats of the urethra. The difference is very much like that which exists between an aneurism formed by rupture of the middle coat of an artery, and one formed by dilatation of all the coats. M. Gillette's operation would have been useless in Mr. Tait's case.—*The Lancet*, May 6th and 20th.

Boracic Acid as a Dressing for Wounds, etc.—This acid has been introduced as part of Lister's antiseptic treatment, but Dr. Cane, of London, uses it also as a simple dressing, and finds that it is an excellent substitute for the antiseptic dressing, which cannot be generally employed in private practice on account of the lack of skilled assistance. Recent wounds, both simple and contused, heal with wonderful rapidity under its use. Dr. Cane uses a saturated solution made with boiling water, and lints of cotton-wool soaked in this lotion and then dried, when the acid is copiously deposited in fine flaky crystals between the fibres. The wound is first washed with the lotion, and then a pad of dry lint folded three or four times is laid over it and kept in position by pieces of strapping. The lotion proved most serviceable in a case of phlegmonus erysipelas, the part being frequently bathed with the lotion and kept constantly wrapped in linen cloths wetted in the same. As a dressing for old ulcers of the leg the boracic lotion and lint are cleanly, and healing takes place rapidly under its use, sometimes succeeding when all other applications have failed. For boils on the neck and elsewere, the boracic lint is an excellent application; a piece large enough to hide the boil, covered with a piece of gutta-percha tissue, often gives great relief. A poultice made with the boracic lotion and Iceland moss is a capital and efficient remedy for carbuncles and other cases that require poultices. Lastly, the lotion and an ointment made by rubbing down one drachm of the acid with one ounce of simple ointment or benzoated lard, are often serviceable in pityriasis versicolor, tinea circinata, and other vegetable parasitic diseases.

Briefly to sum up the advantages of boracic acid—

1. It is an *antiseptic which does not irritate and inflame*, and so allows the natural processes of healing to go on without much interruption.

2. It is exceedingly simple in its application.

3. It can be used in the shape of lotion, lint, cotton-wool, etc., in combination with most other methods of treatment.

4. Its cost is trifling.—*The Lancet*, May 20th.

Tetanus following the Hypodermic Injection of Quinine.—Dr. Roberts, surgeon of the 9th Regiment of Sepoy Infantry, reports two fatal cases of tetanus following the hypodermic injection of quinine for malarial fever, both occurring in the same week. The first patient received an injection on October 15th, and one on the 16th, each containing three and a half grains of the neutral sulphate of quinine. The chills were arrested and the patient returned to duty six days later, but on the same evening he was taken with tetanic spasms, and died on October 25th. The second case received one injection of quinine on October 17th, which stopped the chills. He was discharged from hospital on the 24th, but on the morning of the 25th he complained of stiffness in the jaws and neck, and died at noon on the next day. These cases were treated with chloral, by the mouth and by hyperdermic injection, morphia, and chloroform. In neither case was there any trace of a lesion of a nerve at the site of the original injections. The doctor attributed the first case to rapid changes in the temperature, cases of idiopathic tetanus being not uncommon in some parts of India at the commencement of the rainy season; but with the second case the coincidence became so marked that he was obliged to admit the connection between the tetanus and the hypodermic injections. There was no evidence in either case that poison had been administered. The doctor had given quinine hypodermically some hundreds of times previously; had always taken it in that way himself, and the civil surgeon of the post had used it upwards of five thousand times, and in all these cases there had not been an authenticated instance of sloughing even, following this treatment. Why, then, should it produce tetanus in these two cases?—*The Lancet*, May 20th.

Vaso-Motor Centres and their Mode of Action.—Masius and Van Lair (Congrès de Bruxelles, Sept., 1875) agree with the theory of Goltz regarding the existence of vaso-motor centres. The conclusions to which they have arrived may be stated as follows: In a physiological point of view, the vaso-motor apparatus is constituted by two principal centres, and by nerve fibres, the greater portion of which unite the new centres with each other. The centres are the cerebro-spinal axis on the one hand, and, on the other, the mass of the nerve cells distributed to the periphery of the vascular system. The fibres of reunion are of two sorts. They are either vaso-constrictor, or vaso-dilator fibres, in part centripetal, in part centrifugal. The two varieties of vaso-motor fibres are often united in the same nerve trunk. The vaso-dilator filaments are usually, however, more active or in greater number. They relax the vascular parietes, diminishing the activity of the tonic centres. The vaso-constrictor and vaso-dilator fibres, which take their departure from the periphery, pass directly to the tonic centres, and these in their turn emit exclusively constricting fibres, which are diffused over the parietes of the vessels.—*Lo Sperimentale*, April, 1876.

Elephantiasis of the Nose.—Dr. N. Matteucci reports (*Bull. delle Scienze Mediche*) an interesting case of a voluminous elephantiasis of the nose successfully removed by Prof. Rizzoli. Very few cases of this deformity have thus far been observed. Three cases have been reported by Billroth, one by Gurlt, one by Barilli, and three by Vangel. The individual operated on by Rizzoli began to suffer from this disease at the age of forty-three. It commenced with the production of small tumors consecutive to an erysipelas of the face. He objected at first to an operation, and it was only when the deformity had progressed so far as to render him a laughing-stock to everybody, that he consented to its removal. There were a number of tumors, three of which were quite large, the total weight was 280 grammes. The diagnosis was soft fibroma of the derma and subcutaneous connective tissue in a condition of proliferation, with hypertrophy of the sebaceous glands. A perfect cure was obtained.—*Lo Sperimentale*, April, 1876.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, July 8, 1876.

THE NATIONAL MEDICAL LIBRARY.

From the time that the formation of a medical library in connection with the Surgeon-General's office was first conceived until the present, no pains have been spared to make it the leading one of the country. In this latter respect it has so far achieved its ambition that it has a just claim to change its title to that of the National Medical Library. All who are acquainted with the growth of this remarkable undertaking are aware that the credit of its success belongs to Assistant-Surgeon John S. Billings, who is still its responsible head. Devoting his whole time and energies to the perfection of the details of his office as librarian, he has made a National Medical Library not only a prospective possibility, but almost an accomplished fact.

The need of such a library cannot be questioned by any one interested in the progress of medical education, and in the proper and judicious development of our intellectual resources. Its location, which before might have been a question of jealous dispute with the different medical and literary centres of our country, is now settled by the circumstances of the remarkable success of the original undertaking. So far has this medical library distanced all others in the number and value of its volumes, that it is not only without a rival, but affords the profession the only hope, for years at least, of having anything to compare with it in completeness, systematic arrangement, and all those other qualifications which should make such a collection of standard and abiding value. Its location in Washington is, then, an accident to which the literati of distant parts of the country must become accommodated, and offset the apparent inconveniences of consultation from a distance by the wonderful facilities which otherwise would never have been offered. Washington, although the governmental seat, can hardly claim to be a literary centre; but still it is quite natural that all national enterprises should focus in the Capital, the conventional if not the actual head-quarters of the nation.

The independent right which Washington may claim for a library has been so unequivocally vindicated that it would be but the waste of words to advocate the claims of any other city. The mountain is there, and as it cannot come to us, we must consider how we can best go to it. We are ready to believe that every ordinary opportunity will be offered to students and authors for free consultation, and every effort made to reduce the difficulties of such consultation to that minimum consistent with the good to the greatest number. A foreshadowing of one of the intentions in this direction is the publication of the catalogue, a specimen fasciculus of which, prepared by Dr. Billings, we have recently received. The idea is to place in the hands of the medical men of this country a well-classified and complete list of the works in this wonderful collection, with the view of laying before them the resources of the library and of affording a very fair and remarkably complete exhibit of the bibliography of all the departments in medicine, from the most ancient time to the present. If we admit the importance of the library at all, the publication of its catalogue becomes a necessity for the development of its usefulness.

With a laudable desire for receiving suggestions in regard to the arrangement of this prospective catalogue, Dr. Billings has issued the fasciculus in question. The specimen submitted is of a combined catalogue of subjects and authors, arranged in dictionary order under a single alphabet. Although this plan is not without its disadvantages, it is practically speaking the best which can be adopted, especially in connection with the convenience of an anatomical classification. Such a general arrangement allows of the widest latitude for systematic detail, cross-reference, and precision, while at the same time the inconveniences of duplication are as much as possible avoided. The general alphabetical heads of the catalogue are conspicuously printed in large black letter, and subreferences and sub divisions in smaller varieties of type. Several styles are given, with a view to test opinion upon their respective merits. We think preference will be given to the arrangement of the general subjects in black letter, that of the authors of treatises in italics, and that of the authors of journal articles and pamphlets in small black letters, with the titles of their articles in nonpareil. The general arrangement of subjects would be almost beyond criticism, were it not that Dr. Billings adheres too absolutely in some places to the alphabetical standard of titles. For instance, there is an undue prominence given to "Account," which is out of all proportion to its value and significance as a titular heading. Under this caption we have titles of eight or ten entirely different subjects, which are buried in the small type and tucked away in the middle of a paragraph. But this is probably an oversight, and will be corrected and made to accord with the more practical aim of the

general work when the catalogue is ready to be printed as a whole. We have said enough of the value of this great library to make it unnecessary to urge upon our medical brethren every effort to increase its usefulness and perpetuate its aims. The publication of the catalogue being one of the means to that end, it behooves the profession of the country to give its hearty endorsement to the project, and to use its influence, individually and collectively, to secure the necessary sanction from Congress for its publication.

Reviews and Notices of Books.

A Manual of Diseases of the Eye. By C. Macnamara, F.C.U., Surgeon to the Westminster Hospital. Phila.: Lindsay & Blakiston. 1876. 12mo.

This work, having now reached its third edition, has fully established its reputation among ophthalmologists as a succinct and faithful guide in the practice of eye diseases. Although by no means voluminous, it treats in a general way of all the diseases of the eye and its appendages concerning which the general practitioner cares to know. It is avowedly nothing but a manual, is intended for nothing more, and as such takes the first rank. The arrangement of the subjects is very commendable, and a great deal of valuable information is crowded into a comparatively small space. Besides woodcuts, it contains several handsome chromo-lithographic plates.

Legal Chemistry. A Guide to the Detection of Poisons, Examination of Stains, etc., etc., as applied to Chemical Jurisprudence. Translated, with additions, from the French of A. Naquet. By J. P. Battershall, Nat. Sc. D. With a preface by C. F. Chandler, Ph.D., M.D., LL.D. N. Y.: D. Van Nostrand. 12mo.

As its title indicates, this work is intended as a guide to the chemical expert in the detection of crimes of murder, poisoning, etc. It is so purely technical, and implies such an amount of practical familiarity with the different methods of laboratory work, in the shape of scientific analyses, etc., that to the general practitioner it possesses only a nominal value. To such, however, as cultivate this specialty it is of special value, as compassing in a comparatively small space all the most improved and trustworthy methods of chemical analysis. The usefulness of the present edition is very much enhanced by an elaborate appendix, containing a list of the literature of toxicology and the allied branches. It is very creditably printed, and contains a number of handsome illustrations.

Surgery of the Arteries. Lettsomian Lectures of the Medical Society of London. 1875. By C. F. Maunder, Surgeon to the London Hospital, etc. Phila.: Lindsay & Blakiston. 1875. 12mo.

Mr. Maunder, in this little work, makes a very important contribution to practical surgery. Although made up of but three lectures (one on aneurism, one on wounds, hemorrhages, and antiseptic ligature, and one on ligature of the main artery, to arrest acute traumatic inflammation), the subjects of which they treat are so exhaustively considered, that they must be carefully studied to be appreciated. The lecture on aneurism, their different methods of treatment, by ligature, compression, etc., etc., is particularly worthy the attention of every practical surgeon.

The Student's Guide to the Practice of Midwifery. By D. Lloyd Roberts, M.D., M.R.C.P. Lond., Physician to St. Mary's Hospital, Honorary Fellow of the Obs. Soc. of Berlin, etc., etc. Philadelphia: Lindsay & Blakiston. 1876.

This manual, written for the instruction of students, may render valuable assistance to the busy practitioner. The author first gives an account of the anatomy of the organs of generation. The physiology of generation follows, and upon these pages are several illustrations, taken from Dalton. The mechanism of labor is spoken of as the basis of a scientific knowledge of the act of parturition, and is discussed in a clear and concise style. The illustrations are very good. Several pages are next devoted to the study of placenta prævia, signs and duration of pregnancy, abortion, diseases of the membranes and ovum, superfœtation, and extra-uterine pregnancy. This brings us to the stages and management of natural labor; and here we regret that the author regards the third stage as separation and expulsion of the placenta and membranes. We believe that it would be much safer to teach that the third stage of labor necessarily includes permanent uterine contraction.

After devoting a few pages to the consideration of the puerperal state, the author proceeds to the study of obstructed labor, protracted and hasty parturition, accidental hemorrhage, rupture of the uterus, and the induction of premature labor. He prefers Dr. Barnes' method in the latter instance. Operative midwifery is then discussed under the head of version, the use of the forceps, craniotomy, Cæsarian section, etc. The remaining portion of the book is devoted to the consideration of puerperal convulsions, puerperal mania, phlegmasia alba dolens, puerperal fever, thrombosis and embolism, and pelvic cellulitis and peritonitis. While presenting what he has to say upon this group of subjects, frequent reference is made to the views held by one of our own countrymen, Prof. Fordyce Barker, of New York.

The book is fairly illustrated, is of moderate size (300 pages), and is well written. It is also evident that the author intended to instruct the student, without confusing his mind with finely-spun theories and conflicting opinions, and in this respect he has given the student valuable assistance.

Archives of Dermatology: a Quarterly Journal of Skin and Venereal Diseases. Edited by L. Duncan Bulkley, M.D. New York: G. P. Putnam's Sons. 1875.

We have here the first volume of a quarterly devoted to skin and venereal diseases, which is in every sense a credit to American literature and deserving of extensive circulation. The general plan of the magazine is somewhat peculiar. There are original articles, clinical reports, and reports of societies, chiefly of the New York Dermatological Society. Then follows the digest of current literature, in which the various diseases are divided into different departments, each of which is taken charge of and the digest written by a collaborator specially fitted for the task. In this way every article published is mentioned, and the more important ones are submitted to analysis. By this means the reader has at his command a complete year-book, and by taking this journal alone can familiarize himself with everything done in the two specialties. In no journal in America has this feature been so thoroughly elaborated, and this alone will make it invaluable to

very many. Besides this analysis of articles and brochures, there are long analytical and critical reviews of the various larger and more important works, all written with great care by men well known and eminently fitted for the task. In the department of original articles we find the names of all the authorities of this country, with those of some foreign countries. In this department are many very valuable contributions which have already attracted much attention abroad. In the clinical department we find brief histories of rare and peculiar cases, without much comment, and certainly no one can peruse it without profit. Taken as a whole, the work is a very valuable one; and it is to be hoped it will meet with such a hearty support as will warrant its continuance.

Reports of Societies.

AMERICAN MEDICAL ASSOCIATION.

Section on Obstetrics and Diseases of Women and Children.

THE TREATMENT OF THE PEDICLE IN OVARIOTOMY.

This Section met on Tuesday afternoon, June 6; Chairman, Dr. Samuel C. Busey, of Washington, D. C.; Secretary, Dr. Robert Battey, of Georgia. The discussion was opened on the treatment of the pedicle in ovariotomy, by Dr. Dunlap, of Ohio, who proposed what he called division of the pedicle, first loosening the tumor from any attachment it may have formed, raising it from its bed, securing the pedicle so as to control the circulation, then cutting into the tumor, probably about one-half through, if not very large, saving enough peritoneum to have a long pedicle, severing the tumor, and enucleating the remaining portion of the sac, after the manner of Dr. Atlee. The bottom of the cup-shaped wound rests on the broad ligament of the uterus. After securing the vessels, pass four or five long loops of silk through the cut edges of the peritoneum, equidistant, and carry a curved metal speculum into the vagina by the side of the uterus, and against the bottom of this wound, making a small opening. The speculum should be placed either at the right or left of the ovary, not back or front of the uterus, and the uterus thus placed under control. Then plunge a small instrument through and pass it in a sufficient depth to penetrate the wound. Pass your loops of silk in the edges of this wound, and any ligatures you may have for securing the vessels down through the speculum, and by drawing on these loops you draw the peritoneum down to the speculum, which last you then withdraw, leaving the peritoneum inverted, and the wounded surfaces closely adopted to each other. A somewhat similar plan might be followed in the case of fibroid tumors. Deaths from ovariotomy seldom result from the mere operation, but from the presence of fluids in the abdominal cavity, either causing inflammatory action by their presence, or by their absorption producing septicæmia.

Dr. John L. Atlee considered that, in patients with a moderately good constitution, drainage tubes were not necessary; with a good atmosphere in such cases there was little fear of septicæmia. The less we meddle with the peritoneum the better. He had performed ovariotomy in 1843, and both his brother and himself had then been called butchers. His first case was one of double ovariotomy, and is still living. The great advantage of a clamp is that you leave nothing behind in the cavity of the abdomen. In one case—a tumor weighing sixty five pounds, with a very short pedicle—the wound opened after a violent fit of coughing, and the uterus protruded, and the cut-off pedicle sloughed off; since which time he has closed the lower part of the wound with a fine needle.

Dr. Dunlap stated that he had also been one of the earliest ovariotomists. The drainage tube should only be used where the peritoneum is wounded by tearing up the adhesion. His plan of operation left the parts entirely free from stretch or pressure. He had never found the functions of the uterus interfered with when the organ was held in that way.

Dr. Hodge, of Philadelphia, spoke of the more favorable termination of cases in private practice than in hospitals. He saw no advantages by the drainage-tubes, and considered them a source of irritation. While the fluid came out, there was an objectionable inlet for the atmosphere. He prepared his patients by preliminary strengthening treatment, and never operated when they were mentally depressed.

Dr. Atlee always purged his patients for a day or two before the operation, and then put the bowels in splints with McMunn's elixir, etc. He gave them afterwards plenty of ice or cold water.

Dr. Sims said that he had formerly tied the pedicle and dropped it inside, but death had in several cases occurred from hemorrhage. He had used the clamp very extensively for several years past. He did not believe that the proper principles of the action of the clamp were generally understood. The objection to the clamp is that the sloughing does not stop at the point at which the clamp restricts the pedicle. No man has seen the clamp separate and leave the wound smoothly healed. There is no adhesion at any other place than between the pedicle and the peritoneal lining of the cavity. If there are no adhesions the case can safely be left without drainage. In one case in which he supposed death had resulted from peritonitis, he found, on post-mortem examination, sloughing of the pedicle extending down an inch below the internal lining of the abdominal cavity. (Several other interesting and difficult cases were detailed in illustration.) Dr. Keith, of Edinburgh, is now using the actual cautery with great success, and Dr. Sims was coming to the belief that the actual cautery is the best method after all. The uterus must not be allowed to fall. Drainage can be effected through the cul de sac, or by a glass or silver tube. Nine tenths of the patients who die do so from septicæmia. There are objections to all the modes of drainage adopted. It would be well to combine drainage of the external wound with drainage of the cul de sac of the vagina.

Dr. Byford thought ovariotomy as practised is too complicated, and hence the occasionally bad results. Patients may die from the retaining of putrid material in the abdominal cavity, as well as from the absorption of granulous matter. He lost one third of his cases when he used the clamp. He had had excellent success with Dr. Dunlap's method. Drainage with a still tube was apt to press injuriously on the patient's intestines. He preferred drainage by the ligature, and was going to employ it universally hereafter.

Dr. Sell, of New York, alluded to the success of Spencer Wells with the clamp. A patient in bad health, with no preliminary treatment, will be likely to do badly under any method of treatment of the pedicle.

Dr. Washington L. Atlee preferred the clamp to any other method. Dr. Keith was very successful with the hot iron, but he is said to select his cases. A

short pedicle does not prevent the use of the clamp. The clamp excludes the dead tissues from the cavity of the peritoneum, keeps the womb perfectly quiet, and does not drag upon that organ or upon the pedicle. A pedicle thrown into the cavity of the pelvis has been known eventually to cause death by adhesion of the intestines. Great danger exists when the tumor itself adheres to the intestines. The tumor must be shelled out of its nest. A proper syphon must be employed in these cases. He had operated 340 times, 200 of which were with the clamp. About 70 per cent. recovered. If you pass a tent down well into the cul-de sac, and bring it out over the arch of the pubis, you will have sufficient drainage. He had sometimes employed three tents in different regions.

Dr. Garrish, of New York, referred to the necessity of putting the patient in a good hygienic condition before operating.

Dr. Page's uterine supporters.

On Wednesday afternoon Dr. R. C. Page, of Washington, described a form of uterine supporter applicable to cases attended with hyperæsthesia of the vagina or uterus, in which a hard material could not be endured. It was made of the finest quality of jewelers' cotton, with long fibre, firmly rolled on a curved rubber rod, and afterwards wrapped in the centre, producing a dumb bell form, with compact and elastic extremities, and a curved isthmus. It is introduced through the Sims' bivalve speculum, and is to be removed at night by the patient, who then takes a hot water injection; the pessary, or supporter, being kept all night in a solution of carbolic acid. The cervix rests on the isthmus of the instrument. The curve and size of the pessary may be adapted to the requirements of the case.

Galvano-cautery batteries.

Dr. Byrne, of New York, introduced several forms of batteries and galvano-cauteries, the plates being platinum and zinc, the fluid used being solution of bichromate of potash, or a little sulphuric acid and water, the latter being sufficiently strong for ordinary cases, the former being employed where greater power is necessary, as in cauterizing the stump of the pedicle. He alluded to the applicability of these instruments to the cauterization of the cervix uteri, cervical canal, and the urethra, in cases of chronic urethritis, and uterine and cervical catarrh. White heat should not be employed; hemorrhage would be more likely to follow. He generally occupied about twelve minutes in cutting through the cervix with the cautery. There should be no hemorrhage whatever, if rightly employed. He referred to the use of the cautery in connection with the clamp in treatment of the pedicle, a second clamp being employed after cauterization. In reply to numerous inquiries as to the applicability of this form of cautery, Dr. Byrne stated that he had not used it for venereal warts; that the pain following the removal of hemorrhoidal tumors was but slight, and easily controlled by a suppository, the patient walking about on the second day, whereas the operation by the ligature was often attended with three or four days of pain. There was a good deal of pain during the operation, but he usually anæsthetized his patient. At the conclusion of his remarks, a vote of thanks was tendered him for his interesting explanation.

Precocious development—early menstruation.

Dr. Marcy, of New Jersey, gave an account of the extraordinary development of a very young child, to which his attention had been called two years ago, and exhibited a photograph of the case. The pubic hair began to grow when she was nine months old. The mammary gland commenced to develop at the first month. She is very precocious intellectually. The vagina measures three inches in depth, and receives the right index finger without pain. The uterus is considerably larger than in its ordinary undeveloped state; there has been no menstruation.

An inquiry was made whether there was anything in the condition of the father and mother to account for it. The profession had bestowed too little attention on pre-natal causes. Might not an amorous or lascivious mother, for example, implant the same disposition in her child? Infants have been known to masturbate on the lap of the mother.

Dr. Sell reported a case which he considered much more developed than this: the "Baby Woman," exhibited by Barnum many years ago. He saw her at the age of three years. She commenced to menstruate at eighteen months, and did so regularly after two years and seven months. The mammary development equalled that of an adult. She was perfectly innocent, with no lascivious expression.' He had the child's age from the mother, not from Barnum. The child was examined by a medical commission.

Dr. Greene, of Michigan, mentioned the case of a young lady who commenced menstruating at three years of age, and died in child-bed at the age of twenty.

Veratrum viride in puerperal eclampsia.

At the meeting of the Section on Thursday afternoon, Dr. Burge, of Brooklyn, referred to the portion of Dr. Busey's address, as chairman of the Section, which alluded to the use of veratrum viride in puerperal eclampsia, and spoke of the satisfactory experience of practitioners of that city with it.

Dr. Hopkins was in doubt whether the remedy should be employed unless the pulse was full and hard.

Dr. Langhorne, of Virginia, advocated the use of the drug, having seen no evil effect from it.

Dr. Battey stated that in Georgia it was highly esteemed in the cases referred to. He would feel reluctant to prescribe it in half drachm or drachm doses, as had been suggested by some. It is not devoid of danger.

The remark was made by a delegate that the saturated solution could not have been the article administered in such doses. He never gave more than four to six drops.

Dr. Langhorne said a distinction should be made between Tilden's tincture, Norwood's, and that of the United States Pharmacopœia, and a large dose of even the weakest of these should only be given when the condition of the brain and nervous system or of the intestines indicated it.

Dr. Battey, of Georgia, reported a case of prostration from three-drop doses.

Dr. Fitch relied entirely on Norwood's tincture, varying the dose with the nature of the case. He gave five or six drops at first, every two or three hours, increasing by one drop until the effect was produced, and then decreasing.

Dr. Bennett, of Ohio, thought that attention should be paid to the fact that eclampsia occurs under very different conditions, requiring a difference of treatment. There may be cerebral hyperæmia or cerebral anæmia. Blood-letting may sometimes be necessary, rather than wait for the slower action of the veratrum viride.

Dr. Greene recommended the use of morphia hypodermically in these cases of eclampsia. He approved

of the use of the veratrum in puerperal fever, followed by administration of brandy and morphia.

Dr. Ohr, of Maryland, had treated every case with the lancet, and lost none; the patient being seated and bled until return of consciousness, and then delivered as rapidly as possible, the inhalation of chloroform being employed, if necessary. He had abandoned the use of veratrum viride. Their recovery to full strength was as rapid as though they had not been bled.

Dr. Jenks, of Michigan, had never used veratrum in eclampsia. We may have to act differently according as the convulsions occur, after or before delivery. In the epileptic form we may with confidence resort to chloroform; in the apoplectic, to the lancet.

Dr. Kerr, of Pennsylvania, thought that under any rational treatment the patients would get well.

CHLORAL HYDRATE IN PUERPERAL CONVULSIONS.

Dr. Eshleman, of Philadelphia, alluded to the use of chloral hydrate in puerperal convulsions, and of ether in puerperal cases. He had never seen convulsions in a patient treated with ether in confinement.

Dr. Didama, of Syracuse, had been able to prevent the occurrence of convulsions for two years past by watchful antecedent care and treatment of his patients.

Dr. Peaslee, of New York, had great faith in the lancet in cases of puerperal eclampsia; but chloroform is frequently indicated, with rapid delivery. It should not be mixed with ether. He never used the veratrum.

Dr. Sims had not had any recent experience with this class of cases.

Dr. Goodrich, of Minnesota, related several cases attended during pregnancy with a large percentage of albumen, all of which were bled and recovered.

Dr. Jennings, of Arkansas, had always bled, but had recently employed with it the bromide of potassium and chloral.

Dr. Busey, in reply to an inquiry of Dr. Fitch, stated that he did not wish to convey the idea in his Address that Goodell's method of correcting false presentation, or Parry's mode of correcting face presentation, was to be considered as meddlesome midwifery. [A motion that the portion referring to puerperal meningitis be taken up, so far as related to its epidemicity, was lost.]

Dr. Sims thought that many diseases followed, not the use of instruments, but because these were not employed when they should be.

PERSULPHATE OF IRON IN HEMORRHAGE.

Dr. Jenks considered the employment of persulphate of iron in hemorrhage as bad practice. The coagulated blood may produce septicemia. Rather than use uterine injections, he believed in the expulsion of the head, and compression and ice. The introduction of the hand into the uterus is a dangerous expedient.

Dr. Chadwick, of Boston, said the experience of prominent members of the Obstetrical Society of London, at a meeting at which he was present, was favorable to the use of the sulphate. The coagula should be washed out with some disinfectant solution, and septicemia would not follow.

Dr. Labarrie, of Kentucky, stated that tincture of iodine had been much employed in Louisville, introduced through catheters, with the nozzle-pipe closed to avoid passing the injection into the fallopian tubes. Ergotin, injected into the muscular tissue of the arm, had also been resorted to.

Dr. Fitch, of Illinois, prevented hemorrhage by anticipation; examining the history and condition of the case, he gives a full dose or two of ergot shortly before the delivery of the child, repeated if necessary. He assists the delivery power by grasping the uterus, keeping it contracted, and employing cord contraction with a pendulum movement. After delivery of the placenta he secures contraction of the uterus by pressure. In his view persulphate of iron injections were not necessary.

Dr. Wilson, of Pennsylvania, in a case of irrepressible hemorrhage, continuing several days after labor, had resorted at last to iodine. The uterus, although only three or four drops were injected, at once contracted, and remained so.

Dr. Sims did not think the sulphate of iron in hemorrhage was quite as popular in London as formerly, on account of the deaths from septicemia. In an alarming case in his own experience, he had wrapped cotton saturated with solution of the sulphate around a pointed piece of whalebone, and at once arrested the hemorrhage when it was introduced. Tampons should be removed as soon after the arrest of hemorrhage as possible. When you take away the cotton, as above described, you take away the greater part of the sulphate.

Dr. Sims was anxious that the treatment of the pedicle in ovariotomy should be the subject of the first day's discussion at Chicago, and he now threw down the gauntlet to the Dr. Atlee and other gentlemen for that purpose.

Dr. Busey's Address was then, on motion, refered to the Committee on Publication.

Dr. Garrish, of New York, referred to the desirability of inducing premature labor in cases of threatened convulsions, of physicians carrying with them in their practice a laryngoscope and ophthalmoscope, etc. The prematurely born child should not be dressed, but placed in a warm bath, and afterwards wrapped in cotton.

The Section then adjourned *sine die*.

NEW YORK MEDICAL JOURNAL ASSOCIATION.

Stated Meeting, June 2d, 1876.

Dr Frank P. Foster, Vice-President, in the Chair.

ON THE PHYSIOLOGY OF THE BRAIN.

Dr. Eugene Dupuy delivered an interesting lecture upon certain points in the physiology of the brain, which may be summarized under the following heads:

First.—Nerve cells not only deserve attention as centres, but also as conductors. Hence the explanation of the fact that a lesion might be located far from the would-be centre of the localizers, and yet produce the same symptoms, and *vice versa*.

Second.—Nerve cells were not permanent. The only permanency about them was the power to develop properties—by heredity and by acquisition—hence the "suppliance theory."

Third.—In the experiments of Hitzig and others, the irritation by electricity did not act on the cortex, which was not irritable, but upon vascular nerves, which, from the pia mater at the spots where electricity generally gives rise to contraction, enter into the convolutions, either alone or along the blood-vessels, whose arrangements were peculiar, but which went beyond the thickness of the cortex, and the strands of nerve fibres, which, after forming the crura cerebri, distributed into the crown of Reil and the internal capsule, etc., were the continuations of the true spinal cord at

those points. A difference in the mode of supply of blood to the different territories of the cortex explained the difference in results obtained by irritation. (See Dr. Dupuy's paper in Soc. de Biologie of Paris, in *Gaz. Medicale de Paris*, 1875, pp. 376 and 600, and those of Roche-Fontaine, *id.* pp. 565 and 648.)

Dr. Dupuy believed that his vascular theory, advanced some time ago, derived support from the very recent researches of Brown-Séquard, Eulenburg and Landois, and others.

Dr. Mary Putnam-Jacobi suggested the following consideration in connection with Dupuy's statement regarding latent power in nerve cells. We were aware that it was impossible to entertain any idea without having first passed through a series of preparatory states of mind; that it was impossible to have an impression without being previously submitted to a number of impressions, which graded into each other according to a definite line of succession. The question then became, whether that succession of ideas or succession of impressions was connected with the gradual growth of ganglion cells, each group corresponding to an impression, or each one corresponding to a fragment of an idea or impression? If so, the psychological problem, practically or theoretically, was connected with the nutrition of the brain, with generation of the ganglion cells, which must be presumed to follow a definite line of descent and inheritance.

Dr. Dupuy stated that he would speak upon that point in a future discourse.

The subject of Dr. Dupuy's remarks was further discussed by Drs. McIlvain, Peters, Hamilton, and Foster.

Correspondence.

UNUNITED FRACTURE OF UPPER END OF FIBULA.

UPPER FRAGMENT DISPLACED BY ACTION OF BICEPS, AND CONSEQUENT INJURY OF THE EXTERNAL POPLITEAL NERVE.

Prof. Hamilton, to whom the history of the following case was sent, writes:

The case related in the accompanying note is of special interest. The fracture of both bones of the leg at this point is unusual. The refusal of the fibula to unite, on account of the contraction of the biceps, suggests the propriety of flexing the leg in treating such a fracture, or of dividing the biceps at once.

The hyperæsthesia, pain, and paralysis of certain portions of the foot is plainly due to some injury inflicted upon the external popliteal nerve, probably by the pressure of the upper fragment; and I have said to the doctor that the biceps ought to be divided, or the upper fragment of the fibula dissected. Yours truly,

Frank H. Hamilton.

43 West Thirty-second Street.

Prof. F. H. Hamilton,

Dear Sir:—Having sustained a fracture in my own person, resulting, in part, in non-union and slight deformity and disability, and not finding a record of any similar case in your Fractures and Dislocations, nor in any other work we have here, I have considered it of sufficient importance to communicate it briefly to you. The injury occurred by being capsized while riding in my covered buggy, and being dragged underneath it a short distance, my legs being on the ground wrapped in a buffalo-robe. When finally released from the buggy, I found I had sustained a fracture of the leg. It proved to be a transverse fracture of the tibia just below the tubercle, 2¼ inches below joint of knee, near attachment of the ligamentum patella, and of the fibula, about one inch below its head. It is nine weeks since the accident occurred. I am about on crutches, with a good tibia, but the deformity and disability consists in the fact that the superior fragment of the fibula, with the biceps attached, is drawn upward and inward, so that it lies across the under side of the knee. The head of the fibula seems to rest upon its articulating surface, while its inferior extremity is drawn upward and inward, and is loose and movable. This dislocation of the head of the fibula was not diagnosed at the time of dressing the fracture by the attending surgeon, and in fact I do not know that anything could have been done to overcome the power of the biceps on such a short fragment. The consequence is a loss of the fulness and prominence of the external hamstrings, and weakness of external part of knee, being inclined to easily turn out. The superior extremity, inferior fragment of fibula, seems to be attached by bony union to tibia at seat of fracture, having a depression between that and the superior fragment. I am able to rest my foot upon the floor, but bear no weight upon it. There has also been a paralysis of the extensors of foot and toes, with extreme sensitiveness or hyperæsthesia of dorsum of foot and toes, which still continues.

There has been no appearance of bruise or injury to the anterior surface of the limb, but my foot droops and toes drag. I have been led to communicate this to you from the fact that I could not find anything of similar kind recorded.

E. D. Merriam, M.D.

Conneaut, Ohio.

SALICYLIC ACID IN RHEUMATISM.

To the Editor of The Medical Record.

Dear Sir:—I have noticed with renewed interest the many reports of marvellous cures of cases of acute rheumatism by the use of salicylic acid, which you have from time to time published in your valuable journal, that I am almost inclined to believe, were it not contrary to my own experience, that this disease was really a funny thing to have, now that it is so easily controlled. Everybody, it seems, in the practice of medicine, is using this remedy. Every case that gets well, or is likely to do so, is immediately paraded in some medical journal as another evidence of the *specific* curative powers of salicylic acid. How many times it fails to accomplish the desired result, we know not; for, thus far, only successes are reported, whilst protracted cases and failures are forgotten. It must be, in these instances at least, that they were mild, uncomplicated cases; or that, perhaps, these sanguine writers may have been more favored than some of their rustic brethren, in having selected patients who would get well at all hazards (we mean to be charitable, you see); or possibly that we may have had the old fashioned, long-winded kind of cases away up here in Vermont, for which the late Dr. Warren of Boston would have prescribed as necessary for a cure "a red flannel shirt and six weeks' time."

We like to believe all we can in what we read; but, after much "cramming," we have oftentimes been reminded of the fable of "the toad and the ox," besides experiencing considerable difficulty in deglutition. But seriously, Mr. Editor, is it quite the thing to report

single cases as they occur in our practice, immediately they begin to improve, irrespective of any benefit to be derived from the clinical study of a large number? And is it honest to so isolate them, and because they may perchance speedily recover (some will, you know, get well quickly on almost any kind of treatment), to say nothing of those which run a protracted course? We think not; and it is with this feeling that we are induced to report the other side of the story. We mean to be honest and fair, and so unhesitatingly affirm that in some cases salicylic acid will seemingly do wonders. There are others in which it is of no apparent avail, having neither any particular influence in subduing pain and inflammation, nor diminishing the duration of the disease. Here the old remedy, tr. colchicum sem., will be the *sine qua non* for getting us out of a bad fix; at least it has proved so in our hands after failure in the use of salicylic acid.

We have varied our doses so that the quantity taken ranged from grs. v. to ʒij. every four hours. We have given as high as grs. xxx. every hour for six hours, then decreased the dose in the following manner: 30 grains every two hours for the next six hours; 30 grains every three hours for the next six; and finally settled upon 20 grains every four hours, finding that, in spite of the remedy, the disease still continued on. A week's trial not relieving the patient, there was added to the salicylic acid—which, by the way, was taken in capsules—tr. colchicum, sem., gtts. xv. every four hours; and during the second week the patient got better. "*Mirabile dictu*," the patient decidedly improved in two weeks! During the third he so far improved as to resume work, contrary to advice. After a few days of manual labor he gave up again, almost as bad as ever. An attempt was made to resume the salicylic acid treatment, but objection being made to it, the patient was finally placed upon other treatment, and now seems to be doing well.

In our other case the disease ran four weeks, regardless of the salicylic acid, of which there was taken 15 grains every four hours, from beginning to end. Here, then, are two cases in which salicylic acid was used, in both of which the effect, as far as marvellous results are concerned, is certainly not very flattering. It may be claimed that they are not fair tests. Perhaps they are not. In the practice of medicine we are unfortunately surrounded by just such cases—whatever the disease—in which such considerations as fairness should be no criterion of the true value of a remedy. What we want is *such a remedy as will induce relief in all kinds of cases*, if that is possible; such as morphia for the relief of pain, and quinia for chills and fever. If mild cases of rheumatism are benefited by salicylic acid, how much have we improved upon either acetate of potash and tr. colchicum sem.?

In the administration of this remedy we have found gelatine capsules far more convenient than any other form. We propose to continue its use, for we have found interesting features connected with it. In large doses, such as we have mentioned, tinnitus aurium, slight giddiness, and deafness have supervened, reminding one of the action of quinia. This was the reason why our patient refused to take any more. Another interesting feature was the profuse diaphoresis which it induced, with but slight alleviation of pain. In neither of them was there any particular irritability of the stomach, except a little nausea in one, which soon passed off, without change either in the dose taken or time of administering it being made. In neither was there any "constant burning pain," so frequently mentioned as experienced in the stomach.

It will be noticed that we have given no carefully prepared account of our cases; this we did not intend to do. As our experience was not flattering, we have merely called the attention of the profession to it, in hopes, by appealing to them, we may be enabled to ascertain whether they have had a like experience with ourselves, or whether, by actual observation and practical tests, they too "have found at last, as 'Stricker has intimated,' a real remedy for rheumatism." If their experience is in any wise similar to our own, please let us have it, that salicylic acid, as a remedy for acute rheumatism, may not rest entirely upon "humcombe." Very truly yours,

FRANK W. PAGE, M.D.

BRANDON, VT., June, 1876.

Medical Items and News.

DR. STROBRIDGE SMITH died at Wappinger's Falls, Dutchess Co., N. Y., on the morning of the 9th of June, 1876, from albuminuria. He was born at Crown Point, N. Y., in March, 1828, commenced the study of Medicine in 1843, and graduated at the Castleton Medical College in Vermont. After practising medicine in Ticonderoga for a period of three years he removed to New York City, and attended lectures at the New York Medical College, from which institution he received a diploma in 1855, and entered upon the practice of his profession in the City of New York, where he occupied several prominent positions, and enjoyed a large and lucrative practice. During the late civil war he was appointed Major-Surgeon to the 93d Reg. N. Y. S. Vols., and served with his regiment in Virginia. He was subsequently appointed Medical Director of a Division in the Army of the Potomac. As an honorable gentleman and skilful surgeon, he became a favorite of the commanding officer, and won the respect of all who knew him. After leaving the service he travelled abroad, and during his residence in Paris made a special study of diseases of the eye and ear. Returning to New York City, he continued the practice of medicine and surgery, but his health not permitting a residence in the city, he decided to remove to the country, and finally settled in practice at Wappinger's Falls, New York. Dr. Smith was a man of great integrity, superior general knowledge, sound professional principles, and his demeanor towards all was modest and unobtrusive. During his life he won the confidence of his patients, and also the most favorable opinion of all his professional brethren. His death will long be lamented by those connected with him in professional and social relations.

The following action was taken by the Dutchess County Medical Society, of which Dr. Strobridge Smith was a member, at a stated meeting held on the 14th day of June, 1876:

Resolved, That in the death of Dr. Strobridge Smith the Dutchess County Medical Society loses an efficient member, and the profession at large a physician and surgeon of extensive professional and literary culture and sound judgment,

Resolved, That we deeply sympathize with the relatives and friends of the deceased;

Resolved, That the corresponding secretary transmit a copy of these resolutions to the family of the deceased and to the New York medical journals, to the *Wappinger Chronicle* and the *Fishkill Journal*.

JOHN H. DOUGHTY,
N. M. VAN KENNON,
W. J. CONKLIN.

Medical Congress of Seville.—The *Cronica Oftalmologica* contains an account of the proceedings of the Medical Congress which met recently at Seville, the first reunion of the sort that has taken place in Spain. Papers were read on "The Mineral Waters of Andalusia, and their Use in the Treatment of Skin Diseases;" on "Phthisis in Andalusia;" on "The Nature and Treatment of Puerperal Fever;" on "Cancer;" on "Scurvy;" on "The Treatment of Lachrymal Fistulas by Cauterization of the Sac;" on "Alcohol as a Surgical Dressing," etc. The importance and interest of these different papers afford a good augury for the next Congress, which is to meet at Granada in the coming year.

Commencement of Long Island Hospital, Brooklyn, N. Y.—The seventeenth annual commencement of this institution took place on the evening of June 22d, at the Athenæum, Brooklyn. The degree of Doctor of Medicine was conferred upon the following gentlemen:

Ransom W. Brown, D.D.S.; Alexander B. Van Wagner; John B. Zanparle; John B. Carder; F. E. West, A.M.; Charles A. Briggs; D. F. Brooks; A. O. Squier; J. R. Willis; F. C. Davis; A. D. Decker; John Avery; C. V. Hasbrouck; George F. Ketcham; W. F. McLean; H. H. Hahn, A.B.; John C. Fisher, A.B.; S. W. Meade; O. S. Brigham, Ph.B.; C. G. Brown, B.S.; B. F. Black; W. W. Baldwin; Wesley Sherman; F. J. Withington; A. O. Douglass; J. H. Trent; Alexander McMillan; Henry J. Hesse, A.B.; A. G. Heaney; G. G. Williams; L. A. Denton; C. A. Freeman; George W. Brush; A. D. McLaren, B.M.; D. F. Everts, M.D.; J. C. Davidson; A. C. Bolton; M. F. Bruce, A.B.; Solomon Merrill; E. R. Connell; T. H. Northridge; F. L. Gage, A.B.; R. R. Thompson; G. B. Ayres; J. W. Leadenham.

Prof. Rodman then presented a case of instruments to Mr. Henry Hesse, and a forceps to Mr. O. J. Brigham, they having been offered as prizes by Prof. E. S. Bunker for the best report of his lectures during the last session of the college.

The Hon. Joshua M. Van Cott then delivered the oration of the evening, his subject being the Legal and Ethical Standards of Professional Duty and Responsibility.

After the rendering of some music by the band, the valedictory was delivered by Mr. H. H. Hahn, A.B., M.D., of the graduating class, who was warmly applauded during his address. Benediction was then pronounced by Dr. Dixon, and the audience retired.

A New Journal.—Among our exchanges is *l'Année Médicale*, a new monthly journal, which is to be the organ of the Medical Society of Caen and of Calvados. The contents of the number before us are sufficiently varied and interesting. There is a chatty letter from Paris, giving a report of one of M. Tillaux's clinics at the Hôpital Lariboisière. Among the original articles is the report of a case of rachitic deformity of the pelvis in its conjugate diameter, necessitating the induction of premature labor. The patient had a rachitic history, but there was no deformity of the limbs. In the bibliographical department are short but very good reviews of Tillaux's Topographical Anatomy as far as it has yet appeared, and of Labbé's Surgical Clinics. In addition, the number contains a good many news items that are mainly interesting to the practitioners of its native district. In conclusion, we should add that the new journal seems to be ably edited, and we trust it will have a long and extended career of usefulness.

Maternal Impressions — Dr. G. H. Gray, of West Meriden, Conn., writes:—Dear Sir:—A rather peculiar case occurred recently in my practice. A little girl, playing near a bonfire, came too near the flames and her clothing caught fire, burning her so badly that she died from the effects the following morning. Her mother—who had just reached her full term of pregnancy—in trying to save the child was herself so badly burned about the hands as to render them both useless for the time.

All the women of the neighborhood were gathered, and almost the first question asked me was, "Will this mark the child unborn?" Of course I gave evasive answers, as I was doubtful if she could be delivered of a live child. To my surprise labor was rather retarded than hastened by the occurrence, the mother for forty-eight hours doing little but moving about helpless and despondent, and constantly moaning.

The child was born asphyxiated, but after strenuous and protracted efforts I was at last rewarded by a welcome cry. The curious part of it is, that from the moment of that first cry the child has hardly for an hour ceased uttering a ridiculous fac-simile of the mother's moans, and the old women declare this is the "mother's mark."

Scientific Careers.—M. Fremy, of Paris, the eminent chemist, thinks that he has discovered a means for winning back to the study of science those who now desert it for more lucrative pursuits. He proposes to create for *savans* a modest progressive pension comparable to that offered by the State to the soldier or the civil engineer. According to this project the scientific career is to comprise five grades. The *savans* of the 5th grade are to receive pensions of $600 per annum; those of the 4th grade, $1,000 per annum; those of the 3d grade, $1,600; those of the 2d, $3,000, and, finally, those who reach the first grade, $4,000. A special jury is to be appointed to determine the capacity of the young *savans*, and to propose them for advancement, according to the amount of real service that they have rendered to science. M. Fremy's plan is ingenious and captivating, but, unfortunately, in conceiving it he has given no thought to the many and apparently insuperable objections that present themselves to it.

Our Reports of Meetings of Societies.—The number of Medical Associations held during the past month has been so large that we experience the greatest difficulty in finding space for them. So far we have done the best we could under the circumstances, and shall endeavor to publish those still waiting for their turn as soon as the present crowded condition of our columns will permit. The summer vacation of the Societies, and the absence of more Society material, will make the fulfilment of this promise an early possibility.

False Certificates.—A. M. Boiron has just been condemned, by the Court of Assizes of Paris, to five years' hard labor for having procured false certificates by means of which he obtained admission to the Montpelier Medical College. He was about to pass his examination in the name and place of a certain M. Crespin who had gone to Spain.

Medical Students in Italy.—According to the *Bulletin Officiel de l'Instruction Publique*, 2,802 students have matriculated this year at the different medical schools in Italy. The medical school of Naples heads the list with 991 students; then come Turin, with 361 students; Padua, 251; Pavia, 250; Bologna, 176; Rome, 157; Genoa, 128; Pisa, 104; Modena, 78; Sienna, 69; Parma, 61; Palermo, 60, etc.

New York, July 15, 1876.

THE MAN AND THE TURTLE.

We have at length had an opportunity of bringing the ever-vexed question of the sea turtle, and how to behave towards him, to a plain issue. The result cannot but be regarded as a hopeful sign by all those who wish to see such subjects decided by the light of scientific investigation rather than by the testimony of partly-formed opinions or by individual sentiments, where ignorance or infatuation is pretty apt to play an important part. This case is an excellent exemplification of the ill-advised attempts of a certain class of persons to oppress the community by their views on questions of which they show themselves extremely ignorant. In their persistent efforts to accomplish certain objects they have set before them, they obtain letters and statements from well-meaning persons, who in a general way give their evidence that this or that way of treating the lower creation appears to inflict cruelty or suffering upon them.

This is as it should be, and those gentlemen of eminence among us who will volunteer testimony in such matters merit a large share of public esteem. Their statements, however, would hardly be regarded by the gentlemen themselves as of special value in individual cases, where they had not personal or practical knowledge. It was at this very point that Mr. Bergh's case was weak, and had indeed so little inherent strength, that it suddenly collapsed. According to *The Times* of July 2, 1876, Mr. Blackford, a fish-dealer of Fulton Market, was charged in the Court of Special Sessions with violating the law "in tying the flippers of turtles by means of strings or wythes passed through them, and by keeping the turtles lying on their backs while exposed for sale." Thirty-nine turtles were found at the place, all of them tied in the manner described, and all lying on their backs. The officer who found them "examined the perforations in the flippers of one of them, and found a quantity of clotted blood about the mouth of the orifice. On squeezing this part blood flowed out." Evidence was then introduced by Mr. Bergh to show that such treatment probably produced suffering, which doubtless few would be willing to deny. The defence then introduced Dr. Read, a well-known and prominent minister of the Baptist Church, and formerly President of Shurtleff College, Illinois. This witness narrated some experiments which he had instituted with turtles, having taken two of equal weight and subjected the one to the usual method of treatment, while the other was placed on his belly. At the end of a week the one placed upon the belly was weak and emaciated, and its flippers and undershell badly chafed. The other one was apparently in almost as good a condition as when he had taken it into his house. A number of other experiments were then narrated as to the quality of the respiration, desire for water, condition of the eyes, etc., all going to show that the position on the back, with the flippers pinioned, with a slight support under the head, was the best position for the animal. At the conclusion of these statements Dr. Read was cross-examined by Mr. Bergh, when the Court decided that the case should be dismissed.

It is an unfortunate thing for us that the great mass of our citizens are so busy about their own personal affairs that little time is left for public matters, even when questions of serious import for the general welfare are at stake. The result is, that almost any one who will take the trouble to interest himself in such matters will be virtually undisturbed, however wild or fanciful his ideas may be, unless perhaps he happen to encroach upon the interests of some influential association or some department of trade. And yet we have among us abundance of persons who could undertake the solution of many of these questions, and in a short time could give a showing of evidence that would be generally accepted as credible. In the absence of such testimony Justice sometimes miscarries.

In the present case all theories were at once disposed of by the quiet, methodical investigations of a single man. It is to be hoped that the case will prove a fruitful lesson to Mr. Bergh, and that he will appreciate the value of the evidence that has been brought against him.

We have no desire to throw ridicule upon Mr. Bergh or his Society, or to belittle their operations in mitigating unnecessary cruelty to animals; but it has long been apparent to many medical men, as well as to others of the community, that the practical enforcement of some of Mr Bergh's doctrines would not only be an unnecessary oppression upon business men, but might seriously obstruct the present progress of medicine. It is in this latter regard that the medical profession has persistently opposed some of his recent efforts, and we are thankful to say that they have been successful.

In the matter of marketable flesh and fish it is quite

evident that, apart from humanitarian considerations, the interests of the importer and market dealer lie with the turtle. That plan of carrying and caring for the animal that shall best conserve his comfort and well-being will also be the plan for the dealer to adopt, as in that way the animal will live longer, and therefore be longer marketable. It is interesting to know that the old plan, which doubtless has in a crude way been found best by the dealers, has also proved to be such by scientific observation. And here we should merely say to Mr. Bergh that in such cases the only way he can have of securing the verdict of intelligent opinion upon his side is by employing experts to conduct systematic comparative investigations upon the various treatments that are thought by him to be cruel and those that are thought to be the opposite.

Cruelty has its physical effects, which are capable of being registered by increase of temperature, quality of respiration, diminution in weight, strength, and capacity for life. These points deserve Mr. Bergh's respectful consideration. And it is proper that the medical profession should notify him that such are the methods in use among them in reaching conclusions on such matters. We can only sincerely hope that he will accept the suggestions in the kindly spirit in which they are given, and we may then perhaps have better ground for hoping that the "voice of the turtle," and other similar disturbers of our peace, will no longer be heard in our land.

ARMY STAFF RANK.

Those who have paid attention to the struggle for increased rank in the medical corps of the army will be relieved to know that something has at last been done in the shape of legislation. A bill has at length been passed having for its object the reduction of the number and the increase in the efficiency of the medical corps. The following are some of its generous provisions:

"Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That the number of assistant surgeons now allowed by law shall be reduced to one hundred and twenty-five; that the office of medical storekeeper is hereby abolished; that from and after the passage of this act, in addition to the grades now allowed by law, there shall be four surgeons with the rank, pay, and emoluments of colonels; eight surgeons with the rank, pay, and emoluments of lieutenant-colonels, to be promoted by seniority from the medical officers of the army; that this act shall not be construed to deprive any medical officer or storekeeper now in office of his commission in the United States Army."

Although some change has been made for the better, the law falls far short of an adequate provision for the medical staff. The reduction of the number of assistant surgeons is made on the score of economy, always an exceedingly good excuse for arbitrary and senseless law-making. This slight drawback to the efficiency of the corps is offset by the promotions which are allowed in the higher grades. Instead of two colonels, as formerly allowed, there are now four; and instead of two lieutenant-colonels there are now eight. Considering that only six colonelships and twelve lieutenant-colonelships were asked for, the concession on the part of the Legislature is far from being illiberal.

Although provision is made for promotion by seniority, we cannot see how it is to be efficiently carried out when there is no plan devised for the proper retirement of the old and used-up officers. But something has been gained, therefore let us be thankful.

PATENT RIGHTS IN MEDICINE.

We publish some letters in the present number concerning the question of Patent Rights in Medicine. As our remarks made on a previous occasion upon the subject were intended to open a discussion, we shall defer our comments until we have had a free expression of professional sentiment.

Reports of Societies.

AMERICAN NEUROLOGICAL ASSOCIATION.

SECOND ANNUAL MEETING.

Wednesday, June 7—First Day.

The American Neurological Association convened in New York City, June 7, 1876, and was called to order at 2 P.M. by the President, Dr. J. S. Jewell, of Chicago.

On motion, it was voted to dispense with the reading of the minutes of the first annual meeting.

Dr. E. C. Seguin, Secretary of the Council, read the Annual Report, which was adopted.

On motion, the Secretary was authorized to dispose of volumes of the Transactions remaining on hand, at cost price, to such of the members of the Association as might wish to purchase them, reserving twelve copies for the future use of the Society.

NOMINATION FOR MEMBERSHIP.

Dr. J. J. Mason nominated Dr. Eugene Dupuy.

The President appointed the following gentlemen as

COMMITTEE ON NOMINATIONS.

Drs. Webber, of Boston; Lente, of Cold Spring, N. Y.; Cross and Emerson, of New York City; and Shaw, of Brooklyn.

There being no further business before the Association, the first paper for the session was read by the President, Dr. J. S. Jewell,

UPON THE STRUCTURE AND FUNCTIONS OF THE GANGLIA UPON THE POSTERIOR ROOTS OF THE SPINAL CORD.

Dr. Jewell prefaced his paper with limited introductory remarks, in which the following items were

brought forward as having a bearing upon the prosperity of the Association. It was recommended, *First*, that the meetings, for many years, should be held in some one of the three or four largest seaboard cities. *Second*, that all business matters, as far as possible, should be referred to the Council, so as not to consume the time of the Association. *Third*, that during the next three or four years, the election of new members, whether active or otherwise, should be refrained from as far as possible; *i.e.*, until the Society had shown, by the character of its work, that it was thoroughly scientific and respectable. *Fourth*, that committees should be appointed whose duty it should be to report at subsequent meetings upon some specific subject. The members should feel sufficiently interested in their Association to report their best work at its annual sessions.

The doctor then proceeded to read his paper upon the subject announced. He first considered the gross anatomy of those ganglia, and considered their situation, size, shape, color, and consistence. From thence he passed to the consideration of certain questions relating to minute anatomy and function. Prominent among them were—

What were the peculiarities presented by the nerve-cells of which they were composed?

In what direction did their fibres pass?

What were their true function?

The conclusions arrived at by Dr. Jewell were mainly as follows:

The ganglia upon the posterior roots of the spinal nerves contained cells, which were peculiar, as compared with the cells either of the cerebro-spinal axis or of the sympathetic ganglia. They approached more closely those of the sympathetic, but differed from them chiefly in the fact of being much more frequently uni-polar. In the sympathetic ganglia the cells were usually bi-polar. Perhaps in a majority of cases the cells of the posterior ganglia had only a single process, but there were numerous exceptions in the form of apolar or embryonal cells. Both of the processes frequently took their origin upon one side of the cell, and made a partial or even two turns around it before making their departure. In most instances the processes were furnished with myeline. Occasionally the cells had two processes; one direct, the other spiral. The direct contained myeline throughout, the spiral exceptionally contained myeline, which could be seen only at some distance from the cell. The direction of the processes, almost without exception, was towards the periphery. There was no demonstrable connection between the sensory fibres and the posterior spinal ganglia. If there was any influence exercised over the sensory root by those ganglia, there must be some connection between them. Upon that point Dr. Jewell believed that he had had considerable light shed by the preparations made by Mr. R. W. Amidon, of New York, who, it would seem, had shown that there might be a connection between the cells of the posterior spinal ganglia and the sensory root.

Dr. Jewell further believed that he had demonstrated with tolerable certainty that if the sensory roots were divided peripherally to the ganglia, some effect was produced upon the muscles anatomically related thereto. That change consisted in slow atrophy of the muscular fibre, much slower than when the motor root alone was divided, and was not due to a descending neuritis. If the sensory roots were divided internally to the ganglia, no effect whatever upon the muscles would be produced. Whatever the function of the ganglia might be, it had reference to parts lying outside of the spinal cord, and was independent of it. They exercised a trophic influence over the sensory nerve-fibres, and the doctor believed that it was possible to afford some plausible reason why they were placed outside of the spinal cord; unlike the motor roots, which had their trophic centres in the cord. Dr. Jewell was of the opinion that the fibres in the sensory roots, which had been regarded as conductors of recurrent sensibility, came from the sympathetic ganglia, and had their trophic centres in those ganglia, and that they belong to the vaso-motor system, and should not be taken as part of the phenomena of recurrent sensibility. There was no such thing as recurrent sensibility as commonly understood. The paper being open for discussion,

Dr. Webber, of Boston, inquired how soon atrophy of the muscles followed division of the sensory roots.

Dr. Jewell replied that he had not been able to determine that point; and that the time had varied from six weeks to two or three months.

Dr. Webber asked whether there was any lack of reflex tonus which might account for the atrophy of the muscles after division of the sensory root.

Dr. Jewell replied that there had sometimes been slight loss of muscular tone, as indicated by lack of response to the electrical current.

Dr. Webber asked what the nature of the change was which took place in the muscles.

Dr. Jewell replied that there was simply diminution in size, and that atrophy of all the tissues found in the muscles occurred, whether properly muscular or not.

Dr. Webber remarked that it had occurred to him that, perhaps, the diminution in size of the muscles noted by Dr. Jewell, might be explained by the loss of exercise dependent upon loss of tonus in the muscle, and that this change was not analogous to the degenerative changes that followed injury to the anterior cornua of the cord. In one instance there was absolute degeneration, in the other simply loss of size.

Dr. Hammond, of New York, brought forward a single pathological circumstance, which might have some relation to the subject under discussion, and that was with reference to the disease he had called "progressive facial atrophy." As far as he was aware, no rational explanation had been given for the phenomena observed in that affection. He had had the opportunity to make histological examinations in one case, and had found marked diminution both in size and length of the muscular fibres, when compared with those taken from the sound side of the face. Might not that disease, then, be due partially or entirely to the fact that the Gasserian ganglion of the fifth pair was involved, according to the doctrine enunciated by Dr. Jewell? He was inclined to that opinion.

Dr. Jewell remarked, with regard to Dr. Webber's inquiry, that animals had been confined in a state of functional inactivity; and the changes found in their muscles compared with those found subsequent to the production of lesions in those nerves with which these were supplied. The result of the observation had been that degeneration took place, but not atrophy, or, at least, atrophy was not at all well marked. The change which had been noticed after division of the sensory root, was a perceptible diminution in size; but none, or but little, degeneration.

With regard to Dr. Hammond's suggestion, Dr. Jewell was of the opinion that if his observations proved to be correct, some light would be thrown upon the pathology of the affection to which allusion had been made.

Dr. Webber thought that dividing the sensory root and confining the limb were entirely different. A confined limb could not move, it was true, but reflex movements were continually going on, and the muscle received a good deal of the benefit following normal contraction.

In the other case, there was loss of sensibility which would very likely diminish the unconscious action in the muscles continually going on, and would place the limb in an entirely different condition, and a different result might be expected.

Dr. E. C. Seguin, of New York, inquired of Dr. Jewell whether there was any diminution of electro-muscular contractility.

Dr. Jewell replied that it had seemed to him there was.

Dr. Seguin remarked that he would apply that statement to the suggestion made by Dr. Hammond. He had been able to satisfy himself that the electro-muscular contractility, to the galvanic and faradic currents, was preserved intact in progressive facial atrophy: and that finding such reaction would separate the affection from that condition described by Dr. Jewell.

Dr. Seguin further inquired of Dr. Jewell whether any influence upon the vaso-motor system had been noted.

Dr. Jewell replied, frequently so, but apparently having no connection with the progress of the degeneration in the nerve or disorder in the muscle.

The next paper was read by Dr. J. C. Shaw, of Brooklyn, on

HYSTERICAL TRISMUS.

The chief point of interest in the paper related to the hypodermic injection of sulphate of atropia in the treatment of that affection. The doses employed varied in size from $\frac{1}{6}$ to $\frac{1}{60}$ of a grain, according to the effects produced. The doctor recommended its use with the qualification that small doses should be first employed, the effects carefully watched, and their size increased according to the requirements of each case. His case was treated successfully. The largest injection was $\frac{1}{6}$ of a grain, and the largest quantity of the atropia daily used was $\frac{1}{4}$ of a grain.

Dr. Shaw's paper being open for discussion, Dr. Seguin referred to the history of the case related by Dr. Shaw, and corroborated the statements made with reference to its nature, obstinacy and cure.

Dr. Seguin related the history of a case of spasmodic torticollis which had been nearly cured by the hypodermic use of atropia. The patient had submitted to a variety of treatment without benefit; but marked relief followed the second injection of $\frac{1}{60}$ of a grain of the sulphate of atropia, and at the end of two weeks only slight spasm was manifested. The spasm appeared in the afternoon, and the time for using the injection was to be changed to the afternoon instead of administering it in the morning, as had previously been done.

Dr. Jewell believed that hypodermic injection for the relief of pain or spasm should be as near as possible to the seat of the difficulty. The doctor directed attention to the beneficial effects attending the use of morphia and atropia combined in the treatment of cholera, cholera-morbus, obstinate vomiting, etc. In the treatment of cholera he had combined strychnine and caffeine with the morphia and atropia.

Dr. Webber remarked, with reference to the use of atropia in convulsive affections, that he had given it by the mouth with marked benefit. He had in a number of cases, however, noticed that the use of the remedy had been followed by a peculiar sense of weakness in the legs. So great had been the weakness in some instances that the remedy had been discontinued. It had occurred in one case where $\frac{1}{60}$ of a grain of sulphate of atropia had been taken three times a day for about a week.

Dr. N. B. Emerson, of New York, referred to a case of painful paraplegia, depending upon a malignant growth attached to the spinal cord, in which a combination of morphia and atropia was employed; but it became necessary to change the original proportions in the prescription, because the morphine habit was more easily acquired than the habit of taking the atropine.

Dr. J. J. Mason, of New York, presented a well-marked case of

HEMI-FACIAL SPASM

occurring in a man act. 30 years. The spasm commenced in the tongue, extended over the left side of the face, was first tonic and then clonic. The attacks had appeared annually; and had continued about one week. Each spasm had lasted about one minute and a half, and had recurred every four or five minutes during the entire time of the attack. In the intervals between the attacks, the patient had, to all appearances, been perfectly well. There was no malarial or syphilitic history. The first attack was in April, 1874.

Evening Session—First Day.

The Association convened at 8 P.M., and listened to a paper on

PARALYSIS FOLLOWING ACUTE DISEASES,

by Dr. S. G. Webber, of Boston. The paper contained the doctor's own observations and those made by other observers upon cases where paralysis, partial or complete, had followed acute diseases, such as cerebro-spinal meningitis, typhoid fever, variola, scarlatina, diphtheria, etc. He called attention to paralysis and allied affections not of cerebral origin, and endeavored to refer the clinical phenomena to definite pathological changes. A temporary suspension of function might explain some of the cases, and there might be slight change in structure, which disappeared as quickly as purely functional disturbances.

The following is a brief *résumé* of Dr. Webber's paper. There were many cases in which the sequel was so slight that it was impossible to decide where or what the nervous disturbance was.

There was a large number of cases of paralysis which were more severe and lasting than those; and, if grouped indiscriminately, there seemed to be a lack of order, but if classified, they would be found to fall each under its own proper pathological division.

There were many cases in which the lesion existed in the anterior cornua, because muscular atrophy was present, and there was loss of electro-muscular contractility. In other cases there might be sclerosis of the white columns, which could be determined by the attendance of appropriate symptoms. It was quite possible, in other cases, that there was only neuritis, and then there would be no spinal symptoms.

The paper being open for discussion,

Dr. J. J. Mason, of New York, remarked that he had been specially interested in the electrical reactions alluded to by Dr. Webber, and inquired if the doctor had been able to obtain that phase of degenerative reaction where the muscles of the extremities responded to less galvanic power, fewer elements, than was necessary to excite healthy muscles.

Dr. Webber replied that he had.

Dr. Mason remarked that he had never observed

such a phenomenon upon the muscles of the extremities.

Dr. Webber remarked that he had found it in cases where lesion of the peripheral nerves was present, and in one case of infantile paralysis.

Dr. Seguin referred to two cases belonging to the class contemplated by Dr. Webber's paper. One was a case presenting all the external features of progressive muscular atrophy following upon typhoid fever, and occurred in a well-developed and apparently healthy young man. There were no symptoms whatever, except those referable to mechanical disturbances resulting from affections of the muscles. Electrical reaction was not thoroughly studied, but sufficiently so to determine that response to the faradic current was absolutely lost. The case passed from under observation.

The second case was similar to the first, but had a different history and termination. The paralysis followed cerebro-spinal meningitis, and was soon complete, although the patient was apparently in good health. There was wasting of the muscles, chiefly peripheral, and most marked at the extremities of the limbs. There was absolute loss of electro-muscular reaction to the faradic current, but there was preservation of reaction to the galvanic current in the muscles of the forearm and a trace of reaction in the thenar and hyperthenar eminences of the hand. The thighs recovered spontaneously. The treatment consisted in the daily use of the galvanic current. During the second winter of the treatment, the faradic current was employed, because of the improvement in the muscles. Almost complete recovery had taken place. As a last resort, in order to obtain reaction to the galvanic current in the muscles of the anterior part of the leg, Dr. H. B. Sands, of New York, performed tenotomy of the tendo Achillis, and placed the feet in plaster-of-Paris dressings. The idea was to produce relaxation of the anterior tibial muscles, so as to enable them to respond to the action of the current. From that time onward there was steady improvement. The doctor was of the opinon that the lesion was in the anterior horns, and occurred during the spinal fever. Dr. Seguin also mentioned certain paradoxical phenomena observed with reference to electro-muscular reaction:

1. Recovery of voluntary control over the gastrocnemius without return of electro-muscular contractility.

2. Remarkable return of electro muscular reaction in the anterior tibial muscles without marked voluntary control. The special point of interest in the case was the relaxation of muscles secured by tenotomy in order to fully carry out the electrical treatment. That was done in 1872, and primarily for that purpose.

Dr. Hammond inquired of Dr. Webber what he supposed the lesion to be which gave rise, for instance, to paralysis following diphtheria, in those cases in which recovery took place?

Dr. Webber replied that there was probably some lesion of the nerves or spinal cord.

Dr. Hammond.—What lesion?

Dr. Webber referred to cases reported by Oertel and others, in which, after diphtheria, micrococci and minute hæmorrhages had been found in the spinal cord. Buhl had found micrococci and hemorrhages, which had given rise to pressure upon the spinal nerves, thus producing the paralysis. When the new growth ceased, there might remain sufficient of the new formation to produce permanent pressure upon the nerve. When such new tissue or material was absorbed, the nerve would return to its normal condition. So also in the spinal cord, if there was such lesion, the new products might undergo degeneration and disappear. If there was not extensive change, the paralysis ceased with the removal of the new product, but if too much change had been produced in the organic structure, the paralysis remained permanent. The locality and severity of the lesion regulated the recovery.

Dr. Hammond.—Then the lesion is not amenable to treatment by such medication as we have knowledge of at present?

Dr. Webber.—Probably not. In diphtheritic cases the treatment which would check the growth of the micrococci, such as used in the treatment of the diphtheria, would be proper.

Dr. Hammond remarked that he had asked the questions with special reference to a case which had been sent to him by Dr. Brooks, of Cleveland. In that instance, the paralysis followed diphtheria, and was complete. The doctor first entertained the idea that the patient was suffering from congestion of the cord, or acute spinal paralysis supervening upon the diphtheria, and accordingly administered ergot in large doses. The patient, however, grew decidedly worse, and atrophy of the muscles took place rapidly. Sensation was not impaired in the slightest degree. At the end of ten days, a change in treatment was made, and strychnia given in doses of one twenty-fourth of a grain, and gradually increased until one-sixth of a grain was taken three times a day. No physiological reaction was produced by the drug, but improvement was rapid, and the patient was able, at the end of one month, to walk without a cane. The doctor, finally, did not regard the case as one of spinal congestion, nor did he believe that it was one in which diphtheritic deposits had taken place in the spinal cord. He was inclined to regard it as a case not exactly in accord with those reported by Dr. Webber.

Dr. Webber remarked that it was quite possible the ergot had nothing to do with the getting worse of the patient, but that the increase of the difficulty was simply such as was not infrequently seen in that class of cases. In the same sense it might be said that the strychnia had nothing to do with the recovery, but that the patient had got ready to get well, and recovery ensued.

Dr. Seguin inquired with regard to electro-muscular reaction in Dr. Hammond's case.

Dr. Hammond replied that there was no reaction to either current.

Dr. Webber remarked that it must be allowed that if there was diphtheritic deposit in the spinal cord, or about the nerves, when the diphtheria disappeared the nerves might be restored the same as after injury from any other cause.

Dr. Hammond.—Yes; but in his case there was manifestly an affection of the cells of the anterior cornua. "I do not suppose," said the doctor, "that Dr. Webber wishes to be understood as saying that strychnia is not beneficial in the treatment of paralysis following diphtheria."

Dr. Webber.—No; but that, inasmuch as the ergot may not have been of disadvantage, the strychnia may not have been of advantage in the case alluded to.

Thursday, June 8—Second Day.

Afternoon Session.

The Association was called to order by the President, Dr. Jewell, and the minutes of the previous meeting read and approved.

The Committee on Nominations reported as follows:

For President—Dr. J. S. Jewell, of Chicago.

For Vice-President—Dr. F. T. Miles, of Baltimore.

For Second Vice-President—Dr. R. T. Edes, of Boston.

For Corresponding Secretary—Dr. J. J. Mason, of New York.

For Recording Secretary and Treasurer—Dr. E. C. Seguin, of New York.

For Curator—Dr. J. W. S. Arnold, of New York.

The report of the Committee was accepted, and the Recording Secretary instructed to cast the ballot of the Association in the affirmative for the gentlemen nominated.

Dr. E. C. SEGUIN, Secretary of the Council, reported that the resignation of Dr. Meredith Clymer had been received, and that the Council recommended its acceptance by the Association.

The report of the Council was accepted and adopted.

The next order of business being the reading of papers, DR. HAMMOND presented a communication upon

A HITHERTO UNDESCRIBED FORM OF MUSCULAR INCO-ORDINATION.

The patient was also presented, and was a boy æt. three years and ten months, apparently in good health; had not been subjected to exhausting disease; had no paralysis, no derangement of sensibility, no spasm, nothing indicating sclerosis of any part of the cord; no hereditary tendency to nervous disease; was perfectly straight when lying down; could sit without any indication of inco-ordination; could hear well with both ears; could use both hands with freedom when sitting or lying, and he could stand erect when he had his back supported; but the moment he attempted to walk, the head was turned towards the left side, the body stooped to the left, the left hand and arm were held close to the side and breast and were flexed, while the right was thrown out straight behind the body. The boy could direct his steps, but walked with the body and limbs in the position described. It had been supposed that the difficulty might depend upon irritation from congenital phimosis, and accordingly circumcision had been thoroughly performed by Dr. Sayre, of New York, but the intensity of the phenomena of the affection had gradually increased since the operation.

DR. A. MCL. HAMILTON, of New York, remarked that a number of cases, closely resembling the one exhibited, had fallen under his observation, in which adherent prepuce had been supposed to be the cause, but circumcision had not been followed by any benefit whatever.

DR. SEGUIN directed attention to the fact that the position assumed by the patient when walking was analogous to that seen in animals in whom the middle peduncle of the cerebellum was injured.

DR. DUPUY concurred in the opinion given by Dr. Seguin, and believed that there was, in the present case, lesion in the peduncle, between the cerebellum and pons; and that as soon as movement was attempted, there was a more marked contraction of the muscles upon one side than upon the other.

DR. HAMMOND.—But both arms are affected, the right as well as the left.

DR. SEGUIN.—But is not the right limb thrown out to balance the body.

DR. HAMMOND presented a *second* case, with the following history: The patient was thrown from a wagon four years ago, remained unconscious twelve days with a fracture of the skull near the posterior angle of the right parietal bone. He was paralyzed upon the same side. Two years after he came under the doctor's observation, and complained of vertigo, pain in the head, and epileptiform convulsions.

He was trephined, and had had no convulsions since, and the cerebral symptoms had disappeared. He came again with the complaint that he was entirely deprived of virile power. He had also some paralysis of the bladder, but that was improving, and there was some cystitis. How were his present symptoms to be explained?

DR. PUTNAM.—Was there marked depression at the seat of injury?

DR. HAMMOND.—There was, and several loose fragments of bone were removed.

DR. SEGUIN.—What was the condition of the bone?

DR. HAMMOND.—Healthy; and there was no evidence of disease of the membrane below, except very trifling congestion.

DR. DUPUY.—Had the fits been noticed to affect one side alone?

DR. HAMMOND.—I am not able to answer, because the patient was not under observation.

DR. DUPUY regarded the case as an important one, and that it was a further illustration of the fact that irritation of the dura-mater with electricity almost invariably gave rise to motion upon the same side. It was properly a case of reflex paralysis.

DR. HAMMOND thought the paralysis too permanent to be of a reflex character.

DR. DUPUY remarked that reflex paralysis might be permanent.

DR. JEWELL.—Does Dr. Hammond think that the cerebral lesion gives rise to the paralysis of the bladder?

DR. HAMMOND.—There has been no evidence of lesion of the spinal cord, and I think that the paralysis of the bladder therefore is of cerebral origin.

DR. JEWELL inquired how such a high lesion could produce such a low paralysis?

DR. HAMMOND thought it might be explained on the ground that there were spinal nerve-fibres continuous with the cerebrum, and the original injury gave rise to trouble which subsequently produced paralysis of the bladder.

DR. MILES referred to the demonstrations of Goltz with reference to continuous nerve fibres from the cord to the brain.

DR. LENTE suggested the possibility of remaining cicatricial irritation.

DR. WEBNER suggested that the loss of virile power might depend upon lesion of the cord disconnected from the brain lesion; the lesion of the cord not manifesting itself in any other way. The doctor referred to a case in which a man something over sixty years of age had had complete loss of virile power since he was twenty-three years of age, when he was thrown from a carriage, and received only an exceedingly slight injury of the back that gave rise to no special inconvenience, and to no spinal symptoms except the one mentioned.

DR. JEWELL remarked that he had been led to locate the genito-spinal centre at the implantation of the fourth lumbar nerve, as had been first pointed out by Budge.

Now, if that were true, by what mechanism could loss of virile power be produced by cerebral lesion? Dr. Jewell was of the opinion that there was some lesion in the lower part of the cord; and the practical question was, Was the lesion primary or secondary to the lesion higher up?

Dr. Hamilton suggested that the lesion in the cord was secondary.

Dr. Jewell regarded it as quite probable.

Dr. Dupuy remarked that Vulpian had demonstrated that no such centre existed as referred to by Dr. Jewell.

Dr. Jewell remarked that experiments had proved to him there was such a centre, for, by irritating that point, slight contractions of the uterus, bladder, and seminal vesicles could be produced.

Dr. Dupuy remarked that he had seen the same contractions produced by irritating the second thoracic ganglia.

Dr. Putnam was unable to understand how descending degeneration could take place without giving rise to other symptoms.

Dr. Beard remarked that loss of virile power and affections of the bladder might be developed without any symptoms whatever of trouble in the spinal cord. No other symptom being present, we were obliged in some cases to assume that the entire trouble was in the brain.

Dr. Putnam, of Boston, exhibited an ingeniously devised apparatus for utilizing the ordinary gas jet in the application of the

ACTUAL CAUTERY.

It consisted of a long piece of rubber tubing, one end of which was attached to the gas burner and the other to a compound blow-pipe, through which a current of air could be forced by means of an elastic bulb. The elastic bulb was attached to the handle of the blow-pipe by means of a second piece of rubber tubing which carried upon it an ordinary toy balloon, or flexible bag, for the purpose of making the current of air constant. The stream of air drove the gas flame against a platinum cup which surmounted the blow-pipe.

Dr. Putnam also exhibited a *galvanometer*.

The next paper was read by Dr. G. M. Beard, of New York, and was entitled

THE INFLUENCE OF MIND IN THE CAUSATION AND CURE OF DISEASE—THE POTENCY OF DEFINITE EXPECTATION.

Dr. Beard maintained that disease might appear and disappear without the influence of any other agency than some kind of emotion. Mental qualities, like drugs, could neutralize therapeutics, and they could also increase the effects of drugs. Fear, terror, anxiety and care, grief, anger, wonder, and expectation were regarded as the most likely to produce disease. When active and unrestrained, those emotions became more effectual in the production of disease and the destruction of health, than the most potent poison. The doctor cited various circumstances, illustrating how disease might be brought on by mental states; and referred to a late paper read before the New York Academy of Medicine by Dr. Gouverneur M. Smith, upon "The Epidemics of the Century," in which it was claimed that the immunity the people had from the ravages of epidemic diseases was due to improved sanitary measures. Dr Beard was of the opinion that the escape from such diseases was due a great deal to the fact that there was less apprehension of them; and that that element should be taken into consideration in making up the estimate with reference to the value of any means employed for the prevention and control of contagious and epidemic diseases.

Reason, hope, joy, resolution, ambition, self-confidence, expectation, were regarded as elements which contributed to the recovery of patients, restoring them from actually existing disease and from death itself, and might neutralize the cause which gave rise to malarial fever and to epidemics. That was a fact long ago recognized, and it had been both used and tremendously abused.

The doctor then gave an outline of a series of experiments which he had performed, for the purpose of testing how much could be done in the way of effecting cures in cases of rheumatism, neuralgia, sleeplessness, and various forms of chronic disease, by exciting in the patients a *definite expectation*; for example, telling them that upon a certain day or hour, or even minute in some cases, they were to be better or be relieved of pain.

When such predictions were made, a therapeutic force was set in motion, which acted constantly, day and night; and if, by resolving to do so, any one of us could wake up at a certain hour, we should be able to get rid of disease in the same manner. There was no imagination, in the ordinary sense of the term, in the instances in which Dr. Beard had experimented, for the patients were actually sick, and the average results he had obtained were superior to the average results obtained under the other method of treatment, but were not equal to the average results obtained when the two methods, the mental and the medicinal, were combined. The effects which had been brought about through the emotions, had been as permanent as those realized through the agency of medicines or electricity in the same class of patients. It was maintained that in disease, in ninety-nine cases out of a hundred, the emotions were supreme. The knowledge, on the part of the patient, that mental therapeutics was being employed in the treatment of their disease, did not discourage them; and the liability to disappointment in carrying out such therapeutics was no greater than that attending the use of any other remedial measure. Mental therapeutics could be applied to acute and chronic, to functional and organic diseases. As an offset to disapproval of such practice, it was urged that physicians were constantly availing themselves of its assistance, either consciously or unconsciously, but that the great majority used it indiscriminately.

It was not the intention of the author of the paper to discard medicinal or other means commonly employed in the treatment of disease, nor to recommend the substitution of what he had called mental therapeutics for other methods of treatment in common use; but simply to direct attention to the influence which the mind had over the body, whether in health or disease, hoping thereby to stimulate the profession to a more thorough study of the subject, for the purpose of availing themselves of its highest advantages.

While many cases could be cured by mental therapeutics alone, for a majority of cases it could be best used as an adjunct to proper medical means; and when so used, the average results ordinarily obtained in the treatment of disease might be improved by a large percentage.

Dr. Lente raised the question whether the benefits attending the use of hypodermic injections of warm water might not be explained by mental influence equally as well as by pressure and irritation, the usual explanation.

Dr. Hammond remarked that, if the doctrine advanced by Dr. Beard was to be accepted, he should feel like throwing his diploma away and joining the theologians. It was probably applicable in certain cases which had fallen under Dr. Beard's observation, but there was not a tithe of evidence regarding its efficacy for the removal of organic disease. The paper was simply a formulation of results with which the profession had been familiar for more than a hun-

dred years. That cures had been effected in the manner alluded to was undoubtedly true; but the element of deceit was present, because when a patient was told that he was to be cured simply by mental influence, no success whatever would be obtained. If that form of practice was to be prevalent, it should be done under some other guise than that of the practice of medicine. "If," said Dr. Hammond, "I give a patient a glass of water, and tell him with confidence —though he does not know that he is taking water— that he is to be relieved, it may be justifiable; but if it is done generally and kept up, it must be done under its true colors, and then it will fail."

Dr. Beard remarked he was aware that the method of treatment had been employed for hundreds of years; but the point he insisted upon was, that the profession did not employ it in a systematic manner. Some had used it with more system than others, and had studied special ways of acting upon the patient by such means. The object of the paper was not to show anything new, but to introduce to the profession some special experiments, with the view of exciting a more thorough study of the subject. The point of special interest was, to show how we might utilize definite expectation in the treatment of disease. Does Dr. Hammond admit or deny that warts are organic disease?

Dr. Hammond.—I am not prepared to say. I am not prepared to say but that warts are functional.

Dr. Beard remarked that all he claimed was, that physicians could more certainly help their patients by availing themselves of that method of treatment in conjunction with other methods.

Dr. Hammond remarked that Dr. Beard was not qualified to follow that form of practice; that he was too well informed and too intelligent. It was doubtless true that Dr. Milton had cured his patients; and that patients had been cured by the water of Lowell; and that cases of King's evil had been cured by the Royal touch; but if that form of practice was to be instituted, we should go back to monkery—give up our instruments, give up our medicines, and enter a convent.

Dr. Miles, of Baltimore, fully recognized the influence of mind over the body, but regarded the handling of it as far more dangerous than handling the most powerful drugs. To assume to possess a virtue when you had it not, was very dangerous.

Dr. Beard, in reply to Dr. Miles' objection, stated that all of us were brought into the same strait, and met the problem in various ways. We were making use of opium, bromide of potassium, electricity, with the expectation of seeing certain effects produced; but we do not know that opium—

Dr. Hammond.—But we believe it will.

Dr. Beard.—We hope it will.

Dr. Hammond.—No; we have sufficient knowledge concerning the power of opium, that we may speak with certainty concerning its effects.

Dr. Beard.—I give a patient a dose of opium, but I do not know whether it will produce sleep. Opium generally produces sleep, but its action is different upon different persons, and there is a chance that it will fail in the present case. A prediction about the effect to be produced by a dose of bromide of potassium may be fulfilled or it may not.

Dr. Jewell remarked that there were many things which made it credible that mind had a power over the body, and instanced the relief from toothache a person experienced when the dentist's room was reached—an effect unquestionably due to mental influence. Now, while this method of influencing our patients might be carried to excess, it was to be assumed that the honest physician would not do that, and he believed it to be the wish of the author of the paper that the profession should candidly study the question, and endeavor to arrive at a golden mean in the application of this method of treatment. Both extremes should be avoided.

Dr. Putnam had never seen any evidence that cure had been effected by mental influence in cases where actual disease had existed, and did not believe that it was proper to state to our patients what we did not know positively.

Dr. Miles regarded it as making definite promises concerning something of which we had no knowledge; and if the patient could look into our minds, he would become cognizant of the fact that we were deceiving him.

Dr. Webber did not believe that Dr. Beard recommended telling falsehoods to our patients; but it seemed to him that he had approached very close to the border line between truth and deception. Good results, doubtless, could be obtained by the proper use of mental influence, but when we overstepped the truth our profession at once was degraded.

Dr. Putnam regarded the experiments as unscientific, because the emotions could not be isolated.

Dr. Mason objected to the term mental therapeutics, and denied its existence.

Dr. Emerson regarded the experiments as unscientific, because the exact nature of the elements experimented with was not known.

Dr. Hammond believed that if the ideas of Dr. Beard were adopted, we should be descending to the level of all sorts of humbuggery; and he hoped that the paper would not go to the public with the endorsement of the Society.

Dr. Beard regarded the remarks of Dr. Hammond somewhat in the light of a caricature; and claimed there was nothing in his paper which implied that we should throw aside our medicines and resort to humbuggery. The object of the paper was simply to call attention to a special means of using the mind in the treatment of disease—namely, producing definite expectation; but it was not to supplant other methods, or turn the profession into a body of quacks. A further object was to stimulate systematic study of an agent which was daily being employed in the treatment of disease.

Dr. Denny, of Boston, upon invitation, exhibited a series of transverse sections through the human brain, intended to illustrate the minute macroscopic anatomy. The brain from which the sections were made had been undergoing the hardening process, by means of alcohol and bichromate of potash, for two years. The sections were made by the aid of a microtome, and under water; were stained, and mounted permanently in dammar. Dr. Denny received a vote of thanks from the Association.

The President called the attention of the Association to two microscopic preparations by Mr. Amidon, showing what appeared to be a joining of two nerve-fibres at right angles in the posterior spinal ganglia. This arrangement, if verified, would serve to show the connection of the ganglion cells of posterior ganglia with the spinal cord and with sensory nerves, and to explain the trophic action of these ganglion cells.

Evening Session—Second Day.

The first paper was read by Dr. N. B. Emerson, of New York, and entitled

CLINICAL STUDY OF TETANY.

The paper consisted of the clinical histories of two cases, together with quotations from various authorities regarding the identity of the affection. Dr. Emerson believed that the disease was entitled to a distinct recognition. Both cases recovered.

Dr. Webber related the history of a case in which recovery took place.

Dr. Miles mentioned a case in which he had mistaken the symptoms, due to a probable thickening of the membranes of the cord produced by syphilis, for those of tetany. The patient made a good recovery under anti-syphilitic treatment.

Dr. Jewell made inquiry concerning the pathology of the affection.

Dr. Emerson expressed the opinion that the disease was simply reflex and functional.

Dr. Mary Putnam-Jacobi, of New York, upon invitation, participated in the discussion, and referred to two cases, which came under her observation in one of the cliniques in Paris, and in which the symptoms bore a striking resemblance to each other, although one patient, a child two years of age, was admitted for spasms of the glottis, and recovered, and the other suffered from what, at autopsy, proved to be cerebro-spinal meningitis. In the first case, the symptoms of tetany disappeared under the use of musk.

Dr. Seguin referred to two cases, one of tetany, and the other hysteria, in which the symptoms bore a very close resemblance. In the hysterical case, the typical cone-shaped hand was present; and in the case of tetany, at first, no spasm had been seen, but in a short time spasm was developed, and the diagnosis made clear.

Dr. Hamilton referred to a case in which spasm of the muscles was present, and it seemed impossible to make a diagnosis until an anæsthetic was administered, when the symptoms disappeared.

Dr. Miles related the history of a case in which extreme spasm of the muscles of the extremities and trunk was developed, in consequence of pressure upon the spinal cord, produced by an abscess upon the shoulder, rupturing into the spinal canal outside of the dura mater. The spinal cord, when removed, seemed healthy. There were no bed-sores.

Dr. Putnam inquired whether tetany became persistent, as hysterical contractions sometimes did?

Dr. Emerson replied that he had not observed any such cases.

Dr. Swezey, upon invitation, spoke concerning the occurrence of tetanus upon Long Island, and knew it to be a fact that punctured wounds were exceedingly liable in that locality, especially upon the eastern portion of the Island to be followed by tetanus.

Dr. Seguin was of the opinion that

SPONTANEOUS TETANUS

occurred upon Long Island, and

Dr. T. A. McBride, of New York, alluded to cases of spontaneous tetanus occurring in that locality, and mentioned by Prof. T. G. Thomas, of the College of Physicians and Surgeons.

Dr. Miles referred to the spontaneous occurrence of tetanus among the blacks in South Carolina; and

Dr. Dupuy spoke of the very frequent occurrence of the affection in Mauritius.

Dr. Putnam-Jacobi referred to two cases mentioned by Bernard.

Dr. Putnam, of Boston, reported the results of his observation in the use of

CARBONIC ACID GAS IN THE TREATMENT OF HEADACHE.

The result was negative in eight out of nine cases.

Dr. Dupuy referred to the experiments by Brown-Séquard and himself, which led to the recommendation of the gas for the cure of headache. The cure, it was supposed, was effected by reflex action, the carbonic acid gas irritating the pharyngeal and laryngeal mucous membrane. In his experience, cure had been effected for the time being, except in a few instances. In the cases in which failure followed its use, the hysterical element was present.

FRIDAY, JUNE 9—THIRD DAY.

Afternoon Session.

The Association was called to order by the President, Dr. Jewell, and immediately went into executive session.

Dr. Eugene Dupuy was elected a member of the Association.

Dr. Putnam exhibited microscopic specimens of syphilitic artery and sclerosis of the posterior columns of the spinal cord, which were prepared by Dr. Edes, of Boston.

Dr. Hammond presented a case of cross-paralysis, which, with three others, he proposed to make the basis of a paper to be submitted to the Council.

The Association granted permission, and also granted permission to submit a paper upon

CEREBRO-CARDIAC DERANGEMENT,

probably identical with chlorosis.

The first paper was read by

Dr. A. McLane Hamilton, of New York, and entitled

OBSERVATIONS UPON CHRONIC EPILEPSY.

In the analysis which the doctor gave of twenty-seven cases that had fallen under his observation, it was found that some had depended upon uterine disease, others upon masturbation, still others upon the presence of intestinal parasites, and in a certain number of instances syphilitic poison seemed to be the cause of the disease.

The paper gave rise to discussion, chiefly with reference to treatment. The first indication was to remove the cause, if it could be ascertained. To allay erethism and reduce the susceptibility of the medulla, and to administer some general nerve sedative, were the leading secondary indications. In those cases in which there was a tendency to anæmia, the bromides did harm.

The doctor claimed that not more than one drachm of either of the bromides should be administered during twenty-four hours.

In those cases in which there was present a tendency to hyperæmia, ergot in large doses was recommended.

Attacks of *petit mal* could be cut short by hypodermic injections of atropine.

Dr. Hamilton regarded digitalis as one of the most important adjuvants we possessed in the treatment of epilepsy.

Nitrite of amyl was regarded as an agent which could afford temporary relief only, and was chiefly serviceable in those cases in which a succession of fits occurred. The doctor regarded nitro-glycerine as an excellent prophylactic. He had used it in solution containing about one-quarter of a drop to v. ♏ of alcohol, and had found that it produced almost an exact effect with nitrite of amyl, but the effects had been more permanent. The principal point in the treatment which gave rise to discussion, was that relating to the use of small doses of the bromides.

Dr. Hammond did not believe that small doses were of any avail whatever, but that large doses should be

administered and repeated, so as to develop the bromic cachexia as quickly as possible. One hundred and sixty grains a day had been given before any effect upon the paroxysms was produced. Administer the bromides, gradually increasing the size of the dose, until the super-excitability of the pharynx was diminished; and unless that was done it was evident that a sufficient quantity of the drug had not been given. In certain cases in which the paroxysms were kept up by force of habit, nitrite of amyl might effect a cure, but, as a rule, its effect was only temporary.

Dr. Miles regarded it as necessary that bromism should be produced, and it might be necessary to administer more than grs. xl. three or four times a day.

Dr. Hamilton thought bromism injurious, because it depressed the system. He regarded grs. xx. t. i. d. as sufficient, if combined with ergot, which contracted the arterioles.

Dr. Putnam inquired whether the bromides produced their good effect in epilepsy, by contracting the arterioles, or by producing some direct effect upon the nervous centres? Furthermore, was it known that the amount of blood in the medulla was diminished under their influence?

Dr. Cross, of New York, believed that complete bromism should be produced, and that the patient should be kept in that condition for some time.

Dr. Seguin remarked that he never gave less than a drachm of the bromide within twenty-four hours, and frequently as much as grs. 120, or even 160. His rule was to administer at bed-time the maximum dose for the day, because the excitability of the spinal axis was greatest at night. A degree of bromism should be produced in the patient, and the symptoms of true bromism could not be developed by administering only sixty grains a day.

Dr. Seguin habitually administered other remedies in combination with the bromides. He used ergot considerably, and in doses of one drachm of the fluid extract three or four times a day. Strychnia was regarded as almost a specific against the motor symptoms of the bromides. Arsenic diminished the acne of bromism, and in many cases prevented its occurrence. Tonics of various kinds, especially chalybeates, should be given regularly, in order that the bromides might be better borne.

Dr. Hamilton remarked that there were cases in which large doses of the bromides could be used with benefit for a week or so, but that he recommended the regular administration of only grs. xx., t. i. d., and the occasional use of large doses—even to sixty grains.

Dr. F. P. Kinnicutt remarked that his experience was entirely in accord with Dr. Seguin's, especially with reference to the size of the doses of bromides and their combination with other remedies.

Dr. Jewell remarked that it had seemed to him the fits occurred just in proportion as the patient became fatigued. That was not invariably the case, but quite regularly so. He had therefore given small doses of the bromides during the forepart of the day, a large dose after dinner, and the next large one at bed-time. He regarded the production of a certain amount of anæsthesia of the pharyngeal and laryngeal mucous membrane as important.

Dr. Cross raised the question, why administer a large dose of the bromides at bed-time if bromism was all that was necessary?

Dr. Seguin remarked that the effect expected from a large dose of the drug at bed-time was temporary and immediate, and at the same time it contributed to the more permanent influence arising from a certain degree of bromism. If the fit occurred in the day-time, the time of administering the large dose might be changed.

Dr. Miles regarded it as important to find out when the attack, as a rule, occurred, and apply the remedy accordingly.

The paper was further discussed by Drs. Hamilton, Hammond, Dupuy, and Seguin; and in the course of the discussion attention was called to the *nitrite of amyl bulbs* devised by Dr. T. A. McBride.

The next subject brought before the Association was

REGIONAL CEREBRAL DIAGNOSIS.

By Dr. F. T. Miles, of Baltimore.

The case which Dr. Miles narrated was interesting, from the fact that the injury of the brain in a particular locality was connected with the exact symptoms observed before the death of the patient.

The brain injury in this instance occurred in an eminent lawyer who, at the time symptoms were first developed, was cross-examining a witness. A facsimile of his handwriting was exhibited, and it could be seen exactly where irregularities in outline of letters began to show themselves.

From that point the chirography grew more and more illegible, until finally a mere blot was made. The gentleman then rising to address the court, it was perceived that something was wrong with him, and he was removed from the room. He became semi-comatose, had complete right hemiplegia, the right side of the face was completely paralyzed, and *ptosis* of the left eye was strongly marked. The tongue was not paralyzed, but the patient was unable to thrust it out, and there was no paralysis of the muscles of deglutition. There was some anæsthesia upon the affected side. The patient answered all questions affirmatively. The eyes could be made to follow the finger only as far as the median line to the right, when they would stop, and the patient would carry them over to the left side. The case terminated in the usual deep coma and death. Dr. Miles had diagnosticated *crural hemorrhage*, producing ptosis, with paralysis upon the opposite side. At *autopsy* a mass of blood which had so flattened the convolutions, that it could be easily seen beneath the surface, was found in the central portion of the middle lobe of the brain upon the left side. When the sac was opened, the first blood that escaped was fluid; then came a jelly-like mass; and, lastly, a hard clot, not easily broken up, which was probably the original clot that gave rise to the first symptoms. The clot did not break through into the ventricles, but remained enclosed in the substance of the third lobe.

Dr. Miles referred incidentally to a case in which an abscess occupied the same region occupied by the original clot in the case being described, but in which there was not a shadow of motor paralysis. In the present instance, the autopsy proved that the diagnosis was incorrect, because there was no hemorrhage into the crus. The symptoms, therefore, were explained by the double influence produced by the destruction of brain substance, and pressure upon the surrounding parts; and that it was the pressure upon the crus and the third nerve that gave rise to the eye symptoms. Dr. Miles demonstrated his remarks by means of finely executed models of the human brain.

Dr. Jewell remarked that the fact of the symptoms in Dr. Miles' case being due to pressure produced upon parts outside of the real lesion, showed how easily mistakes could be made with reference to diagnosis and prognosis.

Dr. Hammond inquired with reference to dilatation of the pupil and strabismus.

Dr. Miles replied that there was no special dilatation of the pupils, and that he did not observe any strabismus.

Dr. Hammond, from those facts, was inclined to regard the ptosis as entirely independent of intra-cranial trouble. He did not regard the case as one of cross-paralysis, but that the ptosis depended upon some orbital lesion.

Dr. Seguin directed attention to one symptom in Dr. Miles' case which would cast a doubt upon the diagnosis of affection of the crus—namely, the eye symptom. The fact that the patient could not be induced to turn the eye beyond the median line to the right, and tended to look to the left, was in obedience to what occurs in lesions of the hemispheres and not in lesions of the crus. From that fact alone he would have been led to believe that the lesion was not limited to the crus.

LOCALIZATION OF MOTOR CENTRES.

Dr. Eugene Dupuy, of New York, read a paper upon the above subject, which may be summarized in the following propositions:

The cortical substance of the brain was not excitable by any means, either physical, chemical, or mechanical.

The effect of electricity, when applied to the surface of the brain, was not localized, but diffused, and the motor results obtained when electricity was used were not due to the direct action of the irritant, but were altogether reflex.

No part of the brain substance was excitable except the nerve-fibres, and there was no way by which nerve cells could be excited except by exciting the nerve-fibres with which they were connected.

When electricity was applied to the cortex, motion might take place, but it was not the nerve-cells themselves which were put into action, as proved by experiments. The cranium of an animal was laid open, a point made sure, which, when irritated, gave rise to certain motions, and then the pia-mater was rendered opaque by means of hot iron, but motion followed the application of an irritant, the same as before. The wound was then allowed to close, and at the end of a month the electrodes were applied over the dura mater covering the same spot, and motion was produced upon the same side of the body. The dura-mater was then divided, and the white patch in the pia-mater exposed, and then, when the electrodes were applied, slight motion followed, but not so marked as before. The surface of the part was then dried by means of blotting paper, and the electrodes applied, but no motion followed. The sclerosed patch of pia mater was then removed, and the surface dried, but no motion followed the application of the electrodes.

If motion did not take place in the second series of experiments, it was not from lack of cortical substance, because the fibres below were found to be healthy when examined with the microscope.

It was then clear that the motion was not due to disturbance of the nerve cells, nor to disturbance of the nerve fibres, except those in close relation with the blood-vessels. The doctor then undertook the examination of the structure of the brain tissue and pia-mater; and he had found that the only points in the cortical substance where motion could be produced by the application of an irritant, were those supplied by vessels which came from the pia-mater, and dipped deep into the substance of the brain, and had nerve fibres accompanying them. He believed, therefore, that there was a nervous connection between the pia-mater and the fibres from the spinal cord which was continuous, and that motion was produced through that connection when an irritant was applied to the pia-mater.

The paper being open for discussion,

Dr. J. W. S. Arnold, of New York, asked Dr. Dupuy what current he employed to stimulate the brain; the induced or the constant current, or the primary or secondary induced current?

Dr. Dupuy replied that it made no difference with regard to the current employed.

Dr. Arnold remarked that that was an important point to be decided; and that he was convinced the diffusion of the induced current was so great that its action could not be limited, whereas the constant current could be limited, and the exact point from which the action came could be determined.

He had also been able, by means of the constant current, to decompose brain tissue to such an extent that motion in certain muscles or groups of muscles, in response to the electrical irritant, could not be reproduced; and that when such tissue had been examined microscopically, the structure had been found to be entirely changed. He had also found that when certain points in the brain, which seemed to have presiding power over definite sets of muscles, were destroyed by means of the constant current, motion could no longer be produced in response to the electrical irritant.

Those were the arguments he brought against Dr. Dupuy's theory, and in favor of localization of motor centres. Dr. Arnold inquired of Dr. Dupuy whether the motion was due to the irritant effect produced upon the involuntary muscular fibres in the coats of the arteries?

Dr. Dupuy replied that they were.

Dr. Arnold remarked that the action of involuntary muscular fibres was slow, but that the motions produced in response to an electrical irritant applied to the surface of the brain, were instantaneous.

Dr. Dupuy remarked that he had not seen movements follow immediately upon the application of the irritant.

Dr. Arnold remarked that he had records of movements following immediately upon the application of the irritant; and not only so, but that he had measured the difference in time which elapsed before motion was produced when the irritant was applied to the involuntary muscular fibres of the blood-vessels in the brain, and when it was applied to the cortical substance and gave rise to motion in the voluntary muscles in the limbs of the animal, and that there was a very appreciable difference in the length of time which elapsed before motion was produced in the two instances. In all his experiments, also, the brain surface was kept free from moisture.

Dr. J. J. Mason remarked that in carefully performed experiments on clay he had not noticed any difference in the diffusion of the two currents.

Dr. Arnold did not believe that experiments performed in that manner settled the question of diffusibility of the electrical current in the brain.

Dr. Jewell thought that, although Dr. Dupuy's paper was interesting with respect to the question of the mechanism by which the excitation led to the contraction, it did not militate greatly against the doctrine of localization of function, but was simply another method of explaining how the contraction was brought about. If the contraction was due to a modification in the nutrition of the part irritated, that view was just as favorable as any other to the doctrine of localization. The theory advanced by Dr. Du-

puy, for aught he knew, might be correct; but it did not, in his opinion, affect the doctrine of localization of function at all, but was simply another way of explaining the phenomenon of voluntary muscular contraction. He was strongly inclined to believe in the doctrine of localization of function.

At the close of the discussion, Dr. Hammond nominated Dr. J. C. Peters for membership, subject to the action of the Association at its next annual meeting.

Evening Session—Third Day.

The Association was called to order by the President; and, under the head of Miscellaneous Business, it was resolved to hold the next annual session in the city of New York, commencing on the first Wednesday of June, 1877.

The following papers were then read by title, and referred to the Council:

The Development of the Nervous Tissue in the Human Embryo, by Dr. H. D. Schmidt, of New Orleans.

Contribution to the pathology of the Fronto-Parietal Region of the Cerebrum, with Case, by Dr. T. A. McBride, of New York.

Post-Diphtheritic Paralysis, by Dr. J. J. Putnam, of Boston.

On Brain Tumor without choked Disc, by Dr. E. C. Seguin, of New York.

On Tumor of the Pons, by Dr. J. C. Shaw, of Brooklyn.

Dr. T. B. M. Cross, of New York, then read a paper

on the retinal circulation in epilepsy.

The paper contained the opinions of various observers upon the condition of the intra-ocular circulation during epilepsy, and also the results of the doctor's own observations, made in 95 cases. His conclusions were mainly as follows:—In a large proportion of cases there was no change in the intra-ocular circulation in the interval between the paroxysms, and no alteration of any of the structures of the eye. In some cases there was an increased or diminished amount of blood in the retinal vessels, but such change was purely accidental, and not because of the epileptic paroxysm. There might be congestion of the retinal vessels after a fit, but it soon disappeared, whether the fit was nocturnal or diurnal. When anæmia was present, satisfactory results did not follow the use of remedies which were said to increase the amount of blood in the brain.

The paper was discussed by Drs. Putnam, Dupuy, Hamilton, Hammond, and Putnam-Jacobi.

Dr. Putnam raised the question whether the bromide of potassium acted through the blood-vessels or nervous centres, and whether, if contraction of the blood-vessels could be produced in any other way, the same effect would be produced as by administering the bromides?

Dr. Hammond gave a number of reasons for believing that the bromides diminished the quantity of blood in the brain.

Dr. Putnam-Jacobi remarked that, with regard to the question whether the effect produced by the bromides was directly upon the molecular elements of the nerve cells, or first upon the blood-vessels, some light, perhaps, might be shed by the fact of the occurrence of acne while the bromide was being administered. Eruptions similar to acne, as well as acne itself, were developed under conditions closely resembling those present when the bromic cachexia was developed; *i.e.*, after recovery from long-sustained nervous excitement followed by nervous exhaustion. Several cases were cited in which cutaneous eruptions were manifestly of nervous origin, and also cases in which cutaneous eruptions had followed allaying of the excitability of the nervous elements. Might not the occurrence of acne after administration of the bromides, which allay the erethism of the nervous system, be evidence that the effect produced was directly upon nerve elements; and, in addition, that they produced effects upon the blood-vessels?

Dr. Hamilton remarked that he had seen bromic acne fully developed, and the fits continued as violently as at the beginning.

Dr. Putnam, of Boston, exhibited a

section of the spinal column and of the spinal cord removed from the body of a boy who had suffered from fracture and dislocation at the twelfth dorsal vertebra.

The last paper was read by Dr. Allan McLane Hamilton, of New York, and consisted of clinical notes upon two cases of

locomotor ataxia associated with the general paralysis of the insane.

The close of the session having been reached, Dr. Hammond moved a vote of thanks to the President for the uniform courtesy he had manifested while presiding over the deliberations of the Association, which was unanimously carried.

Dr. Putnam moved a vote of thanks to Dr. W. M. Carpenter, of the New York Medical Record, for his assistance in making the notes upon papers and the discussions, which was also unanimously carried. The President, Dr. Jewell, congratulated the Association upon the success which had characterized the present session, and spoke for a steadily increasing zeal and activity in its studies and investigations.

The Association then adjourned, to meet in the city of New York on the first Wednesday of June, 1877.

Reviews and Notices of Books.

The Pathology and Treatment of Child-bed, a Treatise for Physicians and Students. By Dr. F. Winckel, late Director of Gynæcological Clinic, Univ. of Rostock, from second German edition, with additional notes by authors. Translated by James R. Chadwick, M.D., Clinical Lecturer Diseases of Women, Harvard Univ. Philadelphia: H. C. Lea. 1876.

This treatise, which has been the standard one of its kind in Germany, bids fair to take a distinguished place as an authority in this country. Presenting to us the doctrines of the German school, it will form a companion to the American views upon the subjects, alongside of which a comparison can be made.—The range of the treatise is quite extensive, in fact almost exhaustive, giving evidence of much painstaking research by the author, in his desire to work up an extensive foreign bibliographical survey.

The introductory chapter is full of careful description and suggestion, and prejudices the reader in favor of the work as a useful and trustworthy manual. The puerperal affections of the external genital organs, which are treated of in section first, are well presented; but the practical value of the descriptions centres in those which refer to hemorrhages, the varieties of inflammations, and the resulting thrombosis and pyæmia.

Chapter VI. of this section, on the etiology of the so-called puerperal fever, is well worthy of careful study, and is full of valuable and suggestive facts for the consideration of every one liable to treat the malady.

The puerperal diseases of the breasts receive a careful and discriminate treatment in section two; while those of other organs, in section three, receive their due share of attention.

On the whole, the work will be found to be of the greatest value to the practitioner, as presenting the views of a very careful and discriminative observer, and one whose judgment has been tempered by a long and varied experience in the treatment of the different puerperal diseases.

The profession are under great obligations to Dr. Chadwick for the admirable manner in which he has made the translation. Unlike most efforts of its kind, it is a model of classical interpretation of the language of the author.

Correspondence.

PATENT RIGHTS AND PROFESSIONAL CHARACTER.

ELMIRA, N. Y.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—An editorial, in the RECORD of June 24th, opens the way for further inquiry as to the soundness or unsoundness of the Code in making it derogatory to professional character for a physician to hold a patent for a surgical instrument. It seems to me that the misunderstanding which has so long existed among good men in our profession on this point had its origin in a superficial or erroneous comprehension of the *several* moral principles which underlie the subjects of surgical invention and of letters patent. One thoughtful, candid glance at the ethical clause in question will, it seems to me, make the truth of this remark apparent. The clause reads as follows:

"It is derogatory to professional character for a physician to hold a patent for any surgical instrument or medicine; or to dispense a secret *nostrum*, whether it be the composition or exclusive property of himself or of others. For, if such nostrum be of real efficacy, any concealment regarding it is inconsistent with beneficence and professional liberality; and if mystery alone give it value and importance, such craft implies either disgraceful ignorance or fraudulent avarice."

Now the most conspicuous error in this clause consists in classifying two kinds of persons in one and the same verbal expression, and immediately afterward in pronouncing upon both classes the condemnation which is only due to one of them. If the weight of this edict rested simply upon the dispensers of *secret nostrums*, its verdict would be just; but when it includes the inventors and patentees of surgical instruments, it overreaches the bounds of justice. The patentee of a surgical instrument keeps nothing *secret*. He exercises no *craft*, but is eminently open and frank. He shows no *disgraceful ignorance*, but evinces advanced knowledge. He is not actuated by *fraudulent avarice*, but simply desires a fair compensation for his own mental labor and the expenses attending his study. He is not deficient in *liberality* toward his professional brethren. (Might I not almost say that they are deficient in liberality toward him?)

Looking at the subject in this critical light, do we not clearly discover that the Code is correct in condemning *illiberality*, *secrecy*, *craft*, *disgraceful ignorance*, and *fraudulent avarice*, but that it is incorrect in attributing any of these qualities to the surgeon and scientist who simply avails himself of a governmental provision for reaping the pecuniary rewards of his own labor?

If the foregoing be true, then we shall sacrifice none of the exalted principles which have ever characterized the medical profession by making the amendment in the Code which this construction would seem to call for.

And may there not be other arguments besides justice to the inventor that should induce us to make this alteration in the Code?

Those wise men who were the framers of the Constitution of the United States, in order "*to promote the progress of science and useful arts*," gave Congress the power to secure, for limited times, to *authors and inventors* the exclusive right to their respective *writings* and *discoveries*.

Is it true that this provision of Congress, if allowed full sway among surgeons, would be instrumental in *promoting the progress of science* in the field of surgical implements and appliances? If so, then this is another valid argument for removing the inadvertent restriction.

Should this restriction be removed, then the inventor, instead of being classed with the dispenser of secret nostrums, would be classed with the author—better company; and when the author goes to the publisher and asks, "How much will you give me for this manuscript?" the inventor may go to the cutler and ask, "How much will you give me for this instrument?" and the profession at large will stand in the same relation to each; for in buying a book they will pay the author for writing and the printer for publishing, and in buying an instrument they will pay the originator for inventing and the cutler for making.

In neither case is it to be supposed that money is the main object of the physician's study and labor—no, his motive is far nobler; the benefit of humanity; but money is always a proper and legitimate auxiliary to help the philosopher and the philanthropist onward in every praiseworthy undertaking.

Yours respectfully,

T. H. SQUIRE.

CINCINNATI, June 26th, 1876.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—In your issue of the 24th of June you direct attention to this matter as called up by the resolution offered before the American Medical Association to the effect that "it is not derogatory in any physician to take out a patent for a surgical instrument of any kind." In your article you seem willing to do away with a portion of the disabling clause of the Code, to the extent that a physician may patent an apparatus used in medicine, provided it "can also be used in other arts." Now, why draw a line which, if ever drawn at all, would be an exceedingly crooked one—running far out into forbidden fields? Why may we not boldly declare that the present section of the Code is narrow and contracted—of the nature of Trades Unions restrictions rather than those of a liberal profession, prompted more by selfishness toward ourselves than generosity toward mankind—the tyranny of the many over the few under the guise of medical etiquette? Is not this a peculiar profession,

by the joining of which we are divested of one of our rights as American citizens?

Let us look into the *fons et origo* of the patent law. It is this: the community are aware that certain men possess that peculiar combination of faculties which renders them apt at contrivance; they have discovered that to induce such persons to put forth their best efforts they should be rewarded, not only by the esteem of their fellow-men, but *pecuniarily*, for the time, toil, and thought expended, all this aside from the absolute property right which each one has to the result of his labor. Also, they have seen that nothing operates so forcibly in causing an inventor or manufacturer to introduce a new article as the security of future sales; but for this many a valuable invention would now moulder in a dusty attic, or never have been made. Thus thinking, they have formulated the admirable patent laws, protecting the inventor in the product of his time and talent for a limited term of years, after which it becomes the property of mankind. What is the result of this beneficent system? It need not be told; the world knows it. Why, then, should medical art be debarred from the operation of these just and good laws? Why should medical men not be encouraged to put forth their best energies for the advancement of the mechanical part of their profession? "Oh!" it is said, "the primary object of all inventions directly or indirectly connected with the healing art is for the benefit of humanity, and . . . the medical man should be remunerated by the consciousness of contributing his mite to the relief of mankind."* Well, then, let us throw away our fee-tables and throw away our fees. Let us be in fact what we are in theory—an eleemosynary order, pursuing long years of study, expending thousands of dollars, all, that we may be prepared to benefit mankind. Let us cast ourselves with open arms on the generous breasts of that public, with whom gratitude to the physician is the first thought, but tangible evidences the last. No! this is not practical, it will not do for the medical practitioner, neither will it do for the medical inventor.

The entire subject of patents should be stricken out of the Code, and relegated where it belongs—to the laws of the United States. We need have no fear of an inundation of medical patents, for they, as a rule, are worthless, not enough of any one instrument being sold to pay the cost of procuring a patent; neither need we fear oppressive exactions in the way of royalty, for this would only be an equitable division between inventor and manufacturer of the profit which now goes entirely into the pockets of surgical instrument-makers—men who are ready enough to patent any device of their own, and equally ready to derive profit from the ingenuity of their credulous medical friends. If perchance there should be a medical patent so valuable and so indispensable that it should be given to the world free, then let the government purchase it from the inventor at an equitable price and make the donation; but do not demand that the inventor make all the sacrifice. W——.

---

613 Seventh Street, Washington, D. C., June 28, 1876.

To the Editor of The Medical Record.

Sir:—In your journal for 24th June I notice some remarks on "Patent Rights in Medicine," indicating a tendency to relax the Code which prohibits a physician to take a patent for any invention he may make. And in regard to this question I wish to say a few words—an offering of my mite—toward a correct understanding of this matter. A patent can only be granted for some instrument or thing which is beneficial to the public. The art of a physician is directly to this same point, and we will suppose his invention is an instrument to be used in surgery. Now his chief desire *should be* that every practitioner should possess this instrument, because in that way only can the public receive the full benefit of it. The Code requires that this end should be accomplished by a voluntary dedication of the invention to the public; but does that proceeding bring about the desired result? All experience proves that it accomplishes next to nothing, except in exceptional cases. In order that this instrument may go into the hands of every practitioner, two things are necessary: 1, They shall be manufactured; 2, They shall be brought to the notice of and explained to every practitioner. Yes, and a third thing comes in—they must be manufactured at a price which will not exceed the ability of the practitioners to pay. The dedication does not accomplish or even touch either one of these conditions, without which the invention might as well not have been made. The first requires an investment of capital in advance, and upon a hope and prospect of return. The outlay is necessarily considerable. The second likewise requires an advance in capital for advertisements, etc.; and the third is of equal importance. No one will advance this capital, and sink it in absolutely necessary *preliminary operations*, to perfect and make this thing known, if at the moment he has succeeded in making a market all his rivals in business are at liberty to step in and share the profits without any of the preliminary outlay. *Therefore* this instrument does not go into such general use as enables the public to derive such benefit as the philanthropic inventor desired. The result is, it is only manufactured in the most disadvantageous way, *i.e.*, by hand, and without aid from special tools. It only goes into possession of public institutions and wealthy practitioners, to whom expense is of minor importance. It is only manufactured perhaps upon special order or in small quantities, and the expense is enormously exaggerated. But suppose he takes a patent. The manufacture may then be confined to a single party. The monopoly enables that party to advance the required capital with safety, special tools are constructed, and the instrument is produced at a low rate and of superior quality. And the history of inventions shows that exorbitant profits are not imposed, the desire to sell large numbers being best subserved by moderate profits.

Those best acquainted with this subject all agree that the public benefit is promoted by patents; and if this is true in regard to general devices, there is no reason for excepting those devices which are related to medicine.

If the inventive physician hesitates to *profit* by his mechanical invention, because of humanity, it seems the same reason should operate to prevent his daily entry for attendance at the bedside of his suffering patient. But then he can easily forego his royalties if he so desires, and no one will complain, and he can stipulate with the manufacturer whom he licenses that profits shall not be above a certain percentage. However he may do in those regards, the true Code should require him to do all that he can to extend the usefulness of the invention, and that can only be accomplished by means of letters patent.

Respectfully,

R. D. O. Smith.

* This is a quotation from the Record, but it is the foundation-stone on which all those build who support the present attitude of the Code.

THE MICHIGAN STATE MEDICAL SOCIETY AND THE UNIVERSITY OF MICHIGAN.

UNIVERSITY OF MICHIGAN,
ANN ARBOR, June 21, 1876.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—Will you allow me to call your attention to the very unfair impression conveyed by your report of Michigan affairs at the late meeting of the American Medical Association? According to your report it appears that the delegates from the Michigan State Medical Society were ultimately exculpated by the Judicial Council, whereas the truth is that they are even now under charges before that body,—charges, too, of the most serious character, in reference to which the Judicial Council have promised to report at the next annual meeting of the Association.

True, one set of charges was not sustained, but before the Council on the first and milder set a second and much more serious charge was preferred, and when the roll was called the delegates from the Michigan State Society were protested against, and the matter was referred to the Judicial Council.

For the information of those of your readers who were not at the meeting, I may mention that the delegates from the State Society of Michigan are charged with the most improper affiliation with and "aiding and abetting" of homœopathy and other quackery, and the evidence of their guilt is to be found in the published Transactions of the Society for the years 1874 and 1875. The charge was preferred by a member of the medical faculty of the University of Michigan.

Again, you report quite accurately the resolution of Dr. Toner in reference to the aiding and abetting in the graduation of students in irregular or exclusive systems of medicine,—a resolution the principle of which no respectable member of the profession could for a moment hesitate to endorse; but you have inadvertently omitted all notice of the important and pointed resolution moved by my colleague, Professor Frothingham, and without which Dr. Toner's would have had but little practical significance or utility. It reads as follows:—"*Resolved*, that the Judicial Council be asked to investigate and determine precisely the kind of action which shall be regarded as aiding and abetting, and report at its earliest convenience." This resolution was carried without a dissenting voice. The important bearing of these two resolutions upon the controversy which has existed in this State during the last twelve months will at once appear.

Interested and unscrupulous persons have endeavored to persuade the profession of the land that we of this University Faculty have been and are in the position of *aiders* and *abettors* in the graduation of homœopathic students.

We stoutly and most unequivocally deny this charge, and, on the contrary, contend that we have been and are now standing in the breach, and preventing the country from being flooded with homœopathic graduates. We contend that we have been and are engaged in defending this reputable and important stronghold of regular medicine from passing over into the hands of the homœopathic fraternity. Not only so, but we are prepared to prove that for the seeming temporary advantage which homœopathy *has* gained at this point the State Medical Society, which has for three years urged a policy of affiliation with all sorts of quackery, is to blame.

Now, sir, the resolution of Dr. Frothingham will necessitate the calm, full, and impartial investigation of these matters in all their details, and the result will be a decision from which there is no appeal. With this position of affairs we of this Faculty feel thoroughly satisfied. We feel that at last we will get a *fair hearing*; that our case will be *thoroughly sifted*; that blind prejudice and wilful misrepresentation will alike be silenced, and that there is at last a prospect of our receiving from the profession all that we have asked, namely, *justice*. I am, etc.,

DONALD MACLEAN.

PRELIMINARY EDUCATION.

PORTLAND, MAINE, 24th June, 1876.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—Some weeks ago you approvingly mentioned the rule of the Portland School for Medical Instruction, which requires every applicant for admission to undergo an examination in common English branches, unless he can furnish documentary proof of his graduation from at least a respectable academy. Last week the school year began; and, while one-quarter of the students were college graduates, and another quarter had fitted for college, a number of new applicants presented themselves who were obliged to submit to the examination. This was of a very elementary character, consisting of questions in arithmetic (interest, reduction, proportion, fractions), geography, and grammar, the candidates' knowledge of the last study being tested by their ability to correct a badly spelled, constructed, and punctuated passage. Simple as the exercise was, a third of those who attempted it were at once rejected.

Let me give you a few samples of the answers. One man named "the States bordering on the Atlantic in regular order from north to south," as follows: "Mane, New Hampshere, Massachusets, Rhodeisland, Connetieut, New York, Delaware, Verginea." Of the sixteen counties in Maine (his own State), he gave "Cumberland, Nox, Lincon, Aroostoc, Sagadahoc, Somerset." He could not name a single city of continental Europe—in fact, he did not know what "continental" meant—and he had no idea of the location of the Niagara River. He failed on arithmetical problems which most boys of twelve would solve in ten minutes, and the following are fair samples of his spelling:—"Medicle, som, comon, arithmatic, speling, necassary, daley, desgrace."

This was thought to be the worst possible display, until the inspection of a set of papers which showed that the writer of them not only knew almost nothing of arithmetic and geography, but did not comprehend the meaning of ordinary English words. Here are some examples of his cacography:—"Acknoledg, verey, desireable, possesed, pelimenary, edducation, enny, knowledg, clasicts, bleive, Lattin, admitt, arethmetic, nessesary, phycian, capeable, writeing, accerately, daly, desgrace, medisene."

I am aware that it is often objected that an examination of this kind does not gauge a man's capacity for medical work; that some excellent practitioners are abominable spellers, and that many a bright and learned man would shrink from an examination in geography and simple mathematics. I admit that some good physicians are heterographic prodigies. Only the other day a worthy surgeon of my acquaintance, in recording an injury between the hip and knee, wrote that the patient had his "thy jambed." But while such phonetic atrocities may be pardoned on the score of natural inaptitude at one of the most arbitrary and perplexing branches of study, it is fair to insist that, if a man can not re-learn the most of the forgotten geography and arithmetic of his boyhood in a few days, his mental endowments are not

sufficient to warrant any one in encouraging him to enter upon the study of medicine. The deplorable exhibition of ignorance at the examination which I have mentioned compels the belief that there are in most of the medical schools large numbers of students who are utterly unprepared to appreciate what is said to them; for any man can enter almost any school in the country on payment of the required fees, without a question as to his attainments or ability. As a result of this the professors must either talk unintelligibly to a considerable proportion of their auditors, or else, by adapting their instruction to the understanding of the average student, do less than justice alike to their topics and the better class of their pupils.

An entrance examination which requires so inconsiderable an amount of knowledge and training as this in Portland, is certainly nothing to boast of, and I write to you about it not because we consider its existence particularly creditable or worthy of note, but because, as you have shown so much interest in everything pertaining to medical education, I thought you would like to know definitely some of the results of a genuine effort to investigate the qualifications of the men who undertake the study of medicine. You will be pleased to learn that there is a determination on the part of the instructors in the school to rapidly advance the standard of preliminary requirements, and, on and after 1878, to insist upon the elements of Latin and natural philosophy. Yours very truly,

FREDERIC HENRY GERRISH.

Medical Items and News.

DRS. J. R. VAN KLEEK AND J. O. STONE.—At a stated quarterly meeting of the Board of Managers of the New York Society for the Relief of Widows and Orphans of Medical Men, held at the rooms of the New York Academy of Medicine, June 21, 1876, the following resolutions were passed in regard to the decease of Dr. John R. Van Kleek and Dr. John O. Stone.

JAMES L. BANKS, *President.*

GOUVERNEUR M. SMITH, *Secretary.*

Whereas, It has pleased an Allwise Providence to remove suddenly from us our late presiding officer, John R. Van Kleek, M.D., whose labors as a member of the Board of Managers and as President of this Society for two years have contributed largely to the present prosperity of this institution; therefore,

Resolved, That we reverently bow to the wise behest of Him who has promised to be the widow's friend and a father to the fatherless, and whose blessing is vouchsafed upon all efforts of benevolence;

Resolved, That in the death of Dr. J. R. Van Kleek the medical profession has lost one of its most worthy members—one who was ever watchful of its best interests and whose earnest and thoughtful labors have done much to preserve its institutions and harmonize its interests;

Resolved, That we tender our heartfelt sympathy to the members of his family, with the assurance that he has endeared himself to the whole profession and bequeathed an honorable example worthy of the imitation of all its members;

Resolved, That a copy of these resolutions, properly authenticated, be communicated to the family of our late President, and that the same be published in the medical journals of this city. (Signed)

Committee { SAMUEL L. PURPLE, M.D., O. WHITE, M.D.

On coming together so soon after the death of our long-time associate and friend, Dr. John O. Stone, and seeing the chair occupied by him at this Board for so many years now vacated forever, we desire to place on record some appreciation of the love and respect we entertained for the deceased. Therefore, be it

Resolved, That with unfeigned sorrow and grief do we lament the death of our fellow-member of this Board and former President of this Society, as an almost irreparable loss to us and to the Society;

Resolved, That in the death of Dr. Stone the profession in this city has had removed from its midst an accomplished member of it, who was both a high-toned, courteous gentleman and a most agreeable companion;

Resolved, That we commend to the younger members of the profession in this city for their emulation the many virtues of the late Dr. Stone—his love for his profession, his solicitude for its honor, his fealty to its ethics, his conscientious practice of it, his liberality to all of its organizations having the well-being and elevation of its members for their object, his integrity in all things, and the honorable position he attained among his fellows and in the community where he had so long resided;

Resolved, That our profound and heartfelt sympathy with his family, in this great calamity that has so suddenly befallen them, be assured to them; and that the Secretary of this Board be directed to transmit to them a copy of these resolutions;

Resolved, That these testimonials of our love, respect, and esteem for our late associate in this Board of Managers be entered in the record of its minutes. (Signed)

Committee, { O. WHITE, JAS. O. SMITH, ISAAC E. TAYLOR.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from July 2d to July 8th, 1876.

SWIFT, E., Surgeon and Medical Director. Granted leave of absence for one month, with permission to apply for an extension of two months. S. O. 123, Dept. of the Gulf, June 30, 1876.

BREWER, J. W., Asst. Surgeon. Assigned to duty at Fort Bridger, Wy. T. S. O. 88, Dept. of the Platte, June 28, 1876.

SMART, CHAS., Asst. Surgeon. Assigned to duty at Camp Douglas, U. T. S. O. 88, c. s., Dept. of the Platte.

CONTAGIOUS DISEASES.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending July 8, 1876.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.
July 1.....	0	5	26	1	17	53	5
July 8.....	0	5	29	1	37	35	8

DR. L. DEFOREST WOODRUFF, a prominent surgeon of this city, died suddenly July 9th, of acute basilar meningitis.

YELLOW FEVER.—Quarantine Commissioner Judd reports that there is not a single well-marked case of yellow fever in the quarantine hospitals.

DR. ROBERT WATTS has resigned his position of Clinical Lecturer on Diseases of Women in the Medical Department of the University of New York.

DEATH OF STROMEYER.—Stromeyer, the distinguished German surgeon, died of apoplexy, June 15th.

Original Communications.

STATE MEDICINE IN ITS RELATIONS TO INTEMPERANCE AND THE INEBRIATE.

By EDWARD C. MANN, M.D.,

MEDICAL SUPERINTENDENT STATE EMIGRANT INSANE ASYLUM, WARD'S ISLAND, NEW YORK.

(Read before the American Social Science Association, at Philadelphia, May 31st, 1876.)

During the past few years scientific men have been earnestly laboring to impress the idea upon the public that more thought and study should be expended in the direction of the dissemination of the knowledge of sanitary and hygienic laws among the ignorant masses, in order that the public health might thereby be improved and disease prevented. This study of the laws of disease as they affect communities and nations is of very recent origin. We have now come to realize that preventable disease exists in a great measure as a result of ignorance and the violation of physical, moral, and intellectual laws, and a neglect of sanitary precautions. We have also come to realize that for the prevention of disease we must remove ignorance by a sound education of the masses, so that they may both understand and obey sanitary and hygienic laws. Then, and only then, will the preventable be converted into the prevented. We check intermittent fever by draining our land properly. We mitigate the ravages of small-pox by vaccination. We prevent consumption by avoiding a damp, wet soil for our residence. We avoid fever by taking care of the sanitary condition of our dwelling-houses and the purity of our water supply. We prevent the invasion of cholera and yellow fever by proper attention to sanitary and hygienic laws, and by quarantine; but there is a disease which tends directly to the destruction of all physical and mental health of individuals, communities, and nations, which preventive or State medicine has seemed thus far powerless to check: that widespread and universal disease—intemperance. We need more efficient and wiser legislation upon this subject; and although the Legislature undoubtedly has the right to interfere with the personal habits or private business of individuals, when these are productive of direct evil to the public, yet I think their wisdom and intelligence should be directed in the channels of the diffusion among the masses of the knowledge of sanitary and hygienic laws and the penalties consequent upon their violation. The public sentiment must be enlightened and changed before prohibitory laws and statutes will avail. When the masses can be made to understand that by intemperance they are destroying not only their own physical, moral, and intellectual health, but that of their offspring, on whom this curse is inevitably entailed by the laws of hereditary transmission, then, and only then, will the disease—for disease it is—be abated.

In all parts of the civilized world man seeks for some stimulus, the results of which are more or less disastrous to his physical, moral, and intellectual health, according as the liquors employed are strong and fiery, or mild and light. This tendency or appetite for stimulants varies with varying climatic law, with race, fashion, and the character of the stimulant used. The instinct or appetite for stimulants we can not annihilate, and our efforts must consequently be directed towards its regulation, so that it may be properly restrained by education, reason, and conscience. It has been determined with comparative accuracy that the prevalence of intemperance is governed by a cosmic law, which consists essentially in the fact that the tendency to intemperance increases, and its effects on man become more disastrous, as we go from the equator, where intemperance is comparatively rare, towards the northern regions of the globe, where it is both very prevalent and its effects violent. The stimulating nature of the climate of northern regions induces, perhaps, a desire for such stimulants, while the stimulating nature of our climate on the Atlantic coast, combined with the extremes of heat and cold, operates very unfavorably in the production of intemperance,—a tendency to which we inherit from our English ancestors. Before entering upon a discussion of the disastrous effects produced by intemperance, it will be interesting to note the habits and tendencies of some of the foreign countries in this respect, with the effects of indulgence in alcohol upon the physical characteristics of such nations. In Italy the inhabitants use light wines and beer, and crime resulting from intemperance is comparatively rare.* In Greece the people use universally the light wine of domestic manufacture, and consume annually about 3,800,000 bottles; yet intemperance is very rare, and in the published register of deaths in the city of Athens, for nine years, only twenty-six deaths of natives are recorded as the result of intemperance, and this out of a population of about 50,000 inhabitants. In Germany wine and beer are in unlimited use, but without apparent detriment to either health or national prosperity. This is owing to climate, temperament, and mode of life. In Turkey intemperance is confined to the Christian population, as the Mohammedans abstain from drink. As the use of distilled liquors in Turkey has been found to be very detrimental to both physical and mental health, native and foreign wines are in use by the Christian population. In Spain intemperance is rare, although Spaniards drink more or less wine, Burgundy, and aquaidiente. In Denmark beer and brandy are much used, and the mental and physical constitution of the people is injuriously affected by this indulgence. Suicides are frequent from drink. The better classes use the European wines in moderation. The effect of the climate and the uniform good nourishment of the people of Denmark prevent the disastrous effects which would otherwise appear from such a consumption of alcohol. In Ireland the poorer and middle classes use whiskey and porter very freely, and the rich use wines and brandies. A majority of the diseases and nearly all of the crime in Ireland is due to intemperance. In England the liquors principally used are gin, brandy, beer, wine, and cider, and intemperance is very prevalent. All the competent authorities in England concur that a large proportion of all the crime, disease, and early mortality is produced directly by intemperance. In Russia intemperance is very prevalent, the principal drink of the common people being "vodka," which corresponds to our whiskey. Wine, brandy, beer, and ale are also made in Russia, and drunk by the higher classes. In Japan the people are

* During the last few years, however, dipsomania has been on the increase in Italy, and there has been a decided increase of cases of the nervous system and brain, resulting from the abuse of alcoholic liquors. This I deem to be due to the fact that the warm, humid temperature, particularly of Rome, relaxes the muscular and nervous system; the blood circulates sluggishly, thus predisposing to disease, if alcohol be indulged in, by reason of the imperfect oxidation of the tissues.

on the whole decidedly temperate. More or less "saki," a liquor brewed from rice, is drunk, but it is largely diluted with water, and drunk in very small glasses. Very little crime results from intemperance, owing to the division of the people into castes. The upper class, or the "Samonrai," refrain from drink, as they do not wish to endanger their chances of promotion by the Emperor, who makes his selection from the wisest or most skilful men of the upper class. Their ambition for promotion, therefore, keeps this class comparatively very temperate, while the lower classes refrain from drunkenness from a fear of offending the upper classes, their lives and property being at the disposal of the "Samonrai." In Scotland whiskey is universally drunk by the lower classes, and the amount of intemperance thereby induced operates in the production of crime, and has a very unfavorable effect on the mortality of this class. An apparent exception to the law spoken of in the beginning of this paper, that intemperance is comparatively rare near the equator, is found in the natives, or aborigines, of Central Africa, India, West Indies, and the tropical islands of the Pacific Ocean. It is stated that in these localities the natives rival any nations of the globe for beastly intoxication and drunken orgies. The descendants of European colonists occupying these countries are, however, uniformly temperate. If we look at the foregoing description of the drinking habits of different nations, we shall see that the greatest amount of disease and crime resulting from intemperance occur in those countries where the climate and the nervous temperament of the inhabitants renders the effect of indulgence in alcoholic stimulants especially hurtful to the brain and nervous system. This is nowhere more noticeable than in our own country, especially on the Atlantic coast, where the peculiarly stimulating nature of the climate induces a peculiar nervous susceptibility which operates in the production of grave diseases of the nervous system if drinking habits are indulged in.

The evils resulting from intemperance in our own country can hardly be overestimated. Inebriety, insanity, epilepsy, delirium tremens, and chronic alcoholism are among the more frequent, while the laws of hereditary transmission are inexorably preparing the way for a generation of drunkards. The amount of pauperism, crime, and disease produced in this way every year is something fearful to contemplate. In New York it is estimated that 33⅓ per cent. of all deaths are due directly or indirectly to the abuse of alcoholic stimulants, of which it is supposed that $60,000,000 worth are annually sold in this country. According to the report of the Special Commission on the revenue, of which Hon. David A. Wells was chairman, the amount of distilled spirits used for drinking purposes in the United States for the year ending June 30th, 1865, was thirty-nine million gallons. They also estimated the increase in the consumption of these liquors at the rate of ten per cent. per annum, which would make the consumption for the year 1870 amount to three hundred and sixty million gallons. If we add to this the imported wines and the domestic distilled spirits that are consumed, we have a consumption of not far from four hundred and ten millions of gallons. Now, would the unlimited introduction of light wines and beer prevent the amount of intemperance caused by the consumption of this enormous quantity of distilled liquor? Far from endorsing the idea that the prevalence of light wines and beer *diminishes* intemperance in such a climate as ours, I believe it directly *promotes* it; as I think a person, especially one inheriting a tendency in this direction, after indulging in wine and beer for some time, feels a growing desire for some more powerful stimulant, and soon resorts to the habitual use of distilled liquors, such as brandy or whiskey. I doubt very much whether the introduction of light wines into this country, free of duty, would induce people to give up the more powerful stimulants. My own opinion, with all due deference to the opinion of others, is, that an unlimited abundance of light wines would result gradually in increased habits of intemperance, and I do not think it would result in diminishing the sale of distilled liquors. The almost universal use of light wines in France has not prevented the people from resorting to absinthe and other strong stimulants. I think in our own country that intemperance begins almost universally with the use of wine and beer, which habit lays the foundation or creates a desire for a stronger stimulant, and that in this way thousands are annually prepared to become victims of inebriety. In the year 1830 a measure was introduced in England, originating, I believe, with the Duke of Wellington, establishing beer-houses, hoping that they would promote the cause of temperance and prevent the consumption of distilled spirits by the masses. Instead of exerting this benign influence, it was decided by English statesmen that it was increasing and intensifying intemperance. Lord Brougham was so much impressed by this that he introduced into the House of Lords a bill for the repeal of the beer act, although he was at first very sanguine about the amount of good it was going to accomplish. The introduction of beer did not decrease the sale of ardent spirits; and all the judicial, civil, and medical authorities united in their testimony of the increased evils arising from this measure. In the year 1872 the editor of the San Francisco *Pacific* wrote as follows respecting the increased use of wines, consequent upon the establishment of the vineyards of California: "The lowest, slowest, most illiterate, most unimpressible, most unimprovable, if not most vicious population, outside of the great cities, is found in the oldest wine districts of this State, and that the use of the products of vineyards has been the most active cause of this condition of the population; that the increased production and consumption of wine on this coast, in the more recent years, has diminished the use of neither distilled liquors nor lager-beer, but rather increased the demand for both." With our national susceptible nervous temperament, the artificial habits of living, the intensity and excitement of life, and the undue predominance of the nervous temperament, which is gradually taking place in successive generations, would the dangers of intemperance be lessened by the unlimited supply of light wines and beer? I think not. I regard inebriety as a physical disease, and I do not believe that a man whose nervous system is diseased by indulgence in alcoholic stimulants will ever voluntarily abandon distilled liquors for light wines. Such a man feels, when depressed physically or mentally, an irresistible desire, impulse, or craving to seek for the relief which he obtains temporarily from the use of alcoholic stimulants; and this relief he cannot obtain from a decidedly weaker stimulant than that he is accustomed to use. The very nature of the disease consists in the gradual development and growth of this abnormal appetite or craving, until it reaches that point where it renders its unhappy possessor blind to the dictates of reason and judgment, and the slave of this irresistible, insane impulse, by which he is impelled by a terrible *vis-à-tergo*, to gratify his morbid propensity. The sooner this disease theory of inebriety is acknowledged and recognized by the public, and the proper sanitary, hygienic, and medicinal remedies are applied

to this disease, the sooner will it disappear and be classed under the head of *prevented* diseases.

EFFECTS OF INTEMPERANCE UPON INDIVIDUALS AND COMMUNITIES.

The effects of intemperance upon the sanitary condition of individuals and communities is very disastrous. This naturally results from the pauperism and crime, and the moral and social degradation of the masses, consequent upon this indulgence in alcohol, which culminates in the ruin of their physical, moral and intellectual health. This is seen most clearly when countries are visited by epidemics, when it is observed that temperate communities resist disease far better than intemperate ones. Intemperance weakens the constitution, so that it cannot resist the poison of cholera, yellow fever, etc. The desire for alcoholic stimulants is often the result of an abnormal constitutional organization. It also appears as the result of ill health, sunstroke, blows on the head or spine, and severe mental shock, in the same way as do other nervous diseases. Alcohol is not either respiratory or accessory food, as it has been claimed to be. Liebig and others maintained that when alcohol was taken into the system it united with oxygen, and that combustion or oxidation ensued, by which it was converted into carbonic acid and water; hence it was termed by him "Respiratory Food." This theory of Liebig was destroyed by the researches of Dr. Prout, of London, who proved by direct experiment that the presence of alcohol in the body directly *diminished* the amount of carbonic acid gas exhaled from the lungs. These experiments of Dr. Prout were confirmed by Sandras and Bouchardet, of France, who repeated them with like results, and also by scientists in our own country. The chemico-physiologists then maintained that alcohol being a hydro-carbon, must necessarily be used for maintaining temperature and respiration, and that its use increased temperature and strength. Dr. Boker, of Germany, then instituted a series of experiments, proving that the use of alcohol retarded tissue metamorphosis, and thereby decreased the excretion or elimination of effete matter, so that from the accumulation of hydro-carbonaceous material the individual increased in weight. This latter fact led certain persons to claim that alcohol was an accessory food—an erroneous idea, which they would have recognized as such, had they observed such individuals carefully; for they would have seen that such persons always exhibit a corresponding decrease in nervous and muscular stamina. It was proved in 1869 by the experiments of Dr. N. S. Davis that, after taking alcohol, either in a fermented or distilled state, the temperature began to fall within an hour, and continued to fall for two or three hours. A few years later, Lallemand, Perin, and Duroy proved, by a series of experiments, that alcohol was absorbed and carried with the circulation throughout the whole body; and also a very important point that it was eliminated as alcohol, unchanged, from the lungs, skin, and kidneys. Others claim that only a part of the alcohol taken is eliminated. We see, therefore, that alcohol has no claim to be regarded as food, as it is not used to build up the tissues of the body, or repair or restore lost nervous or muscular force. It merely diminishes the nervous sensibility of the individual, so that it lessens his consciousness of impressions, and acts as a sedative by retarding tissue metamorphosis. The nervous sensibility is diminished by virtue of a paralysis of the vaso motor and cerebro-spinal system of nerves, which the alcohol causes as it circulates through the body. The use of alcohol, therefore, to recapitulate, diminishes the temperature, the strength and the power of endurance of the individual who takes it habitually, and increases his predisposition to disease. It impresses a peculiarly morbid influence upon the brain and nervous system, which, if the habit be indulged in, becomes a permanent pathological impression, and results in the formation of an irresistible or insane impulse to seek for the relief obtained from alcoholic stimulants. In this state of moral insanity, the control which the intellect normally exercises over the moral senses is overborne by the superior force derived from disease. This permanently diseased state, or dipsomania, is markedly hereditary, and, like insanity, appearing under other forms, it often disappears in the second generation to break out with renewed intensity in the third. It manifests itself in predisposition or simple aptitude; in a latent state; or in the actually developed disease. In the second or latent state, the germ of the disease, which has been inherited by the individual, lies dormant, perhaps, for years, and starts into life in advanced age; as the result of ill health or mental shock, resulting in mental inebriety in a previously healthy and temperate person. This permanently diseased state of the brain is due probably to the interference in the nutrition, growth, and renovation of the brain-cells, which, by the use of alcohol, are unduly stimulated, so that a process of waste and decay is induced, beyond the powers of reparation and renovation. Owing to this impression of a pathological state on the brain-cells, there results a change of healthy function, and disease is induced. The effect of the alcohol is to cause a change in the chemical composition of the cerebral cells from the standard of health, which is the foundation and the starting-point for organic disease. Owing to long-continued use of alcohol, we have resulting: Cerebral hyperæmia, with symptoms of irritation, due to increased excitability of the nerve filaments and ganglion-cells of the brain. At a later stage, we have symptoms of exhaustion, due to lost excitability of the nerve-filaments and ganglion-cells, owing to a want of the proper supply of arterial oxygenated blood to them. Alcohol not only weakens and impairs the functions of the body, but it causes grave nervous diseases, such as insanity, epilepsy, and chorea, and also influences the offspring of intemperate parents in the most unfavorable manner. The offspring of such parents inherit a predisposition or aptitude for some form of nervous disease, the particular form being often determined by causes subsequent to birth. It may be inebriety, insanity, epilepsy, chorea, or a proclivity to crime. These children, offspring of intemperate parents, are generally cursed with a defective, ill-balanced organization, and a weakened, if not actually diseased, nervous system; as a result of which they are predisposed to seek for the relief obtained from alcohol, when depressed mentally or physically. They soon degenerate, become victims to the irresistible impulse, and die inebriates. Insanity from intemperance is on the increase, especially in England, where it shows an alarming increase, judging from the last reports of one of the largest asylums, the Crichton Royal Institution, where in the last five years the admissions due to intemperance have risen from 8 per cent. to 35 per cent. The Medical Superintendent, Dr. Gilchrist, remarks, that "doubtless a more minute analysis would largely increase the proportion of those in which the excessive use of stimulants, by the patients themselves, or by their parents, constitutes an important, if not the primary factor in the production of mental disturbance." In order to successfully combat all these manifold evils which we have seen result from intemperance, we need to educate

the public up to the universal acceptance of and belief in the fact that alcohol, instead of being a tonic and restorative to the system, is a narcotico-irritant poison; that it has no analogue in the human system; and that its continued use will *inevitably* result, not only in the impairment of the mental and physical health of the individual himself, but also that of his offspring. When the public come to take this view of the subject, and come to believe that mind and body are debilitated, instead of nourished and renovated, by the habitual use of alcoholic liquors, public sentiment will then be adequate, without the necessity of prohibitory laws, to the prevention of intemperance.

INEBRIATE ASYLUMS AND CARE OF THE INEBRIATE.

We have already spoken of the necessity of wise legislation tending to the prevention of intemperance; but what shall we do with the Inebriate? It becomes a grave question relating to the political economy of the commonwealth as to the annual loss entailed on the State by the loss of the labor of inebriates. The average longevity of a man at 20 years of age, if temperate, has been estimated at 44.2 years; while if intemperate, his average life is reduced to 15.6 years. If an inebriate at 20 years of age is not reformed or cured, the State loses his earnings for the 44.2 years which he would have made if temperate; and there is also an expense entailed, for his care, on his family or the State, for the 15.6 years remaining as his average life. When we reflect upon the extent of intemperance throughout the commonwealth, we see what an immense loss is suffered by the State by such a waste of productive power, and what a grave financial problem this subject becomes when viewed in this light. We need, in every State of our country, to establish State inebriate hospitals, adapted in construction, location and surroundings to the special needs of this class of unfortunates, so as to enable them, with the assistance of wise superintendence, to regain their lost self-control and manhood, and have their weakened and diseased minds and bodies properly strengthened and cured. In this way a great annual expense would be saved to every State, by materially lessening the number of paupers, idiots and criminals, to say nothing of the destitute children, and that percentage of the insane who have been rendered so by the abuse of alcohol. If one-tenth part of the sum annually appropriated in each State to almshouses, hospitals, prisons and asylums, should be appropriated to the reform and cure of inebriates, the expenses of the above-named institutions in a short time would be very much lessened, by the decrease in admissions, which would be the natural result of a decrease in the *causes* of pauperism, crime and disease. If, in addition to building Inebriate Hospitals in every State, the Legislature of such States would pass such laws as would enable the public guardians to put into active operation remedial restraint, so that inebriates should be committed in precisely the same manner as are the insane, and held for treatment until the superintendent deemed them fit to take their place in society, we should then soon have accomplished great good in the permanent reformation and cure of men who are admitted with broken-down nervous systems and shattered constitutions. To do this, military discipline, good hygienic influences, cheerful, tranquil, and pleasant surroundings, and regular exercise, both bodily and mental, are among the indispensable indications for treatment, while the superintendent will be best able to judge of the special needs of individual cases. There should be no half-way or sentimental measures adopted in the confinement and treatment of inebriates. The public must understand that inebriation is a type of insanity; and that in all cases, prompt and effective measures will be taken to prevent such individuals from ruining themselves and injuring society. That in all cases prompt measures will be taken to confine such persons in an institution for the cure of inebriates, by law; and that, when there, they will be under strict discipline, which will require and enforce both physical and mental labor, as they are a class of patients, for whom, in my estimation, not less than the insane, physical and mental labor is absolutely necessary for restoration to health. An inebriate who is allowed to idle away his time will never acquire that mental and physicial stamina which is requisite for his reformation and cure. He will only degenerate; and on his discharge will relapse into his former habits. An inebriate asylum where the patients cannot be detained by law until cured, loses much of its efficacy. It must be understood that the inebriate is suffering from a physical disease, and that he is committed to an inebriate hospital to stay until cured, whether that cure takes for its completion six weeks or six years; and that when in such an institution he is to submit to the discipline of the house. If the question be raised, How can you tell whether your patient is cured? I reply, that when reasonable hopes are entertained of the cure of a patient,—when we think that we have given our patient new blood, bone, muscle, and *mind* enough to take care of himself, his family, and his property, then, I would do as I am in the habit of doing with my insane patients, send them out on pass—on trial—still maintaining a legal control over them, and when it is clear that they are going to do well, discharge them. With the insane I have found this plan to work well; why not with the inebriate insane, if they are in like manner legally committed upon admission? For the successful treatment of inebriety, as with insanity, it is necessary to send the patient for treatment in the early and curable stage of the disease. Like insanity, inebriety, if treated in the early and curable stage, ought to give a much larger percentage of cures than it now does; while if the patients are sent for treatment after years of disease, they present small chances for recovery. Yet people do not wish to send their friends for treatment to such an institution until they have become confirmed sots, and beyond all hope of reformation and cure. Such cases should be sent to an *asylum*, and should not be allowed to cumber up the wards of an inebriate *hospital* where we send patients, not to *keep* but to *cure* and return to society. Finally, the Legislature should, in dealing with this question, in addition to legislating in the direction of the dissemination of knowledge among the masses, as to the nature and effects of alcohol, deal with its indiscriminate sale, just exactly as it does with the sale of arsenic or prussic acid, for it is just as surely a deadly poison. Arsenic is sometimes used as food to increase flesh and impart brilliancy to the eye and complexion, but is it not a deadly poison? Opium and haschish are also used, for their effects, in the same manner, but is not their sale restricted, as with all other poisons? The Legislature must appreciate the fact that the use of alcohol is a form of suicide, and must legislate in this direction. No other form of prohibitory statutes will ever accomplish the desired result. I have already alluded to the fact that it becomes at times a very difficult task to convince a man's family that he is a proper subject for an inebriate asylum. I deem it a sacred duty that in such cases devolves upon the governmental authority, to protect society, as in the case of other insanities, against danger, either existing or being

apprehended, such as can be avoided by precautionary and preventive measures, and to protect in his rights of person and property the individual citizen who, from whatever cause, is unfortunately so far impaired in his physical, mental, or moral faculties, as to render his uncontrolled movements alike prejudicial to his own interests and those of society.

NEPHROTOMY FOR THE RELIEF OF PYO-NEPHROSIS—RECOVERY.

By MARK H. WILLIAMS, M.D.,

NEW YORK.

W. H. P., æt. 32, New York; single, printer. Was first called to see patient February 14, 1876, because of a "severe back-ache," which he had endured the previous two weeks, and had attributed to a "cold" resulting from lying on dampened paper while perspiring. He had continued at work until one week ago, and was now obliged to remain in bed, chiefly on account of "general weakness and the pain in his back." Four days ago he had a chill, followed by fever, which has since continued, with daily afternoon exacerbation, terminating later by free perspiration, during which time he suffered less pain.

He gives a favorable antecedent history, being unable to recall any illness that necessitated indoor confinement until within a comparatively recent period. Fifteen years ago a muco-purulent urethral discharge was consequent upon an original indulgence—his only mishap, which proved to be of short duration, and was not followed by stricture. Six years ago, while in China, he dates his first illness, an attack of yellow fever, from which he made a speedy and satisfactory recovery.

Two years ago a rather formidable furuncular eruption appeared on his back, to which poultices were applied, healing rapidly after purulent discharge. In a few weeks this was followed by another crasis showing itself in an isolated manner on arms and legs, disappearing as before under the same local treatment. Although causing him great discomfort, these eruptions did not seem to reduce his general physical vigor; he ate well, and retained his average weight of 160 pounds. In the course of six months the engendering cause was expended, and during the following year he had entire immunity from all "fleshly ills," enjoying excellent health.

Five months ago several deep-seated indurations, attended with pain, and a gradually extending areola, appeared in the posterior tibial region of both legs, the consequent duration of which was evidently limited by free incision, and the internal administration of the solut. hydg. iodid. comp., although no previous specific history could positively be determined.

On the occasion of my present visit I found the patient in bed, lying upon his back, with right leg drawn up, and a peculiarly wearied expression of countenance. His skin was dry and hot to the hand. Tongue thickly furred, yellowish brown in color, and dry. Pulse, 120, temp. under tongue, 103° F.

Constipation had been marked for the past ten days. No change in the quantity of urine voided had been observed. On examining back no pain was caused by pressure over vertebra, or in the left lumbar region; but on being increased over right lumbar space, and particularly over a point two inches to the right of the fourth lumbar vertebra, the pain was so severe as to cause him to cry out. To relieve his present distress, I gave him a subcutaneous injection of morphine, applied wet cups, and advised frequent hot poultices over seat of pain.

A specimen of urine brought me, after standing several hours, was seen to be of dark straw color, containing a flocculent whitish deposit, sp. gr. 1.012, acid. With heat and nitric acid, ¼ albumen in volume. Under microscope, a few blood-corpuscles and a great profusion of pus-cells, with several uric acid crystals and a doubtful spindle-shaped cell (the only one observed at any time); these examinations were daily repeated without further result.

Feb. 21st.—During the following week no marked improvement was manifested. His daily temperature ranged from 102 to 105; pulse averaged 120; considerable thirst; his tongue is more moist, but a dry brown streak continues along median line; has no desire for food; fæces hard and dry, and skin sallow. Diet limited to milk and Saratoga vichy, of which he drinks from three to four pints daily, without relief to his constipation or acid condition of urine; has occasional vomiting; no jaundice, and no abnormal condition other than in right loin, excepting some pain closing the act of micturition, referred to the root of the penis, and for which he requests relief. Examinations of urine present about the same features, with an increased amount of pus. Poultices to back continued; occasional milk punch, and to take 5 gr. quinine with 40 gtts. tr. ferri mur. every six hours.

Feb. 28th.—The patient seemed to improve during the third week; his average temperature was lower, and he had some desire for solid food. He was still annoyed with the smarting after voiding urine, but in a less degree. Complains of swelling of right testicle, with pain at irregular intervals. To apply leeches and poultice.

At this time his urine was lighter in color, and the amount of deposit greatly diminished; the gradual improvement being more perceptible by placing in regular order the three last daily specimens; and under the microscope but few pus-cells could be found. Its reaction was still acid, and albumen remained.

He expressed himself as feeling better than he had at any time during his illness, and urged me to allow him to leave his bed for a reclining chair. Although in a feeble condition, I acceded to his request, and a position by the window afforded him a few hours' relief.

The freedom from pus discharge continued some three days, when it reappeared in increased quantity. This tended to confirm the provisional diagnosis of calculous pyelitis. It was now apparent that the pelvis of the affected kidney was undergoing dilatation (pyo-nephrosis) as a result of imperfect escape to the constantly formed purulent secretion; but to arrive at a perfectly satisfactory conclusion as to the cause, nature, and location of this obstruction was a more difficult matter. In accordance with the symptoms and microscopical evidences, it seemed plausible that a *renal calculus* was the source from which this man's condition resulted. The patient had sat up but one day, and in the latter part of the week pain extended down through right inguinal region to inner side of thigh; he had diminished muscular power in right leg, with *numbness* of three outer toes.

March 6th.—During the fourth week he rests entirely on his right side, unable to lie upon back because of increased pain. The right leg is extended, and he can flex it only with assistance, the movement causing no pain. Urine is voided freely, and no distress follows the act. On employing a searcher, no cause could be ascertained for the bladder tenesmus

he had experienced; the urethra was not unusually sensitive at any part, and no complaint was afterward made against a rather prolonged examination.

March 13th.—The only interesting note of this week's progress was the return of the pain and swelling in the right testicle, which was relieved previously by local abstraction of blood and the application of poultices. On Saturday, March 18th, the testicle measured, in its long diameter, three inches, and transversely, two inches; it was of stony hardness, hot, and very sensitive to pressure; at the lower and inner border the scrotum was adherent, and an obscure sense of deep-seated fluctuation was obtained; this part was freely opened, giving exit to about two drachms of thick, creamy pus; lint was introduced. It healed by granulation, and no further trouble resulted from this source.

At this time the *right side*, measured from the spin. proc. of vertebræ to the median abdominal line, exceeded that of the corresponding left side one inch. Slight bulging was apparent posteriorly, at previous point of greatest pain, on pressure. This enlargement was felt to be firm, and somewhat elastic, and measured, on a line with the inf. angle of scapula, from ninth rib downward, *seven inches;* laterally, from within two inches spi. proc. vertebræ toward median abdominal line, *eight inches.* A fluid tumor was evidently present, although the precise nature of its contents was as yet undetermined.

On Tuesday, March 22d, Dr. J. H. Ripley (to whose valuable advice the subsequent good result is largely due) was called in consultation, and, after obtaining pus by an exploratory puncture with a small aspirating needle, confirmed the diagnosis, and advised a free incision into the kidney, if necessary, rather than simply removing the accumulated pus by aspiration, and Friday, three P.M., was agreed upon for this operation.

The condition of the patient was now extremely critical. During the past week quinine had had no effect upon his high temperature, and hectic, followed by profuse sweating, was of daily afternoon occurrence. He was much emaciated, very pale and feeble, exhausted after speaking but a few words, rarely above a whisper. Aphthous patches in mouth were scattered over tongue, cheeks, and fauces; commencing bed-sores over right trochanter and at sacro-lumbar articulation. This discouraging condition, with no other prospect of relief, caused him to readily acquiesce in any measure that promised to improve his chances of recovery; his only stipulation being that he should not suffer further pain. His nurse was instructed to collect all the urine passed in the ensuing twenty-four hours, that it might be compared with that following the operation. It was found to measure 64 oz., sp. gr. 1.018, acid; one-third purulent deposit; the supernatant clear fluid containing one-fourth albumen.

March 24th, 3 P.M.—*Operation.*—Present, Drs. J. H. Ripley and V. P. Gibney.—Two ounces of brandy, with half a drachm of bromide of potassium, was given patient, after which Dr. Gibney kindly proceeded to place him under the influence of ether.

The particular operation determined upon was that suggested by Thomas Smith, in a paper on "Nephrotomy as a means of treating Renal Calculus," *vide Med. Chirug. Trans.*, April 27, 1869, in which the details are given with commendable particularity.

Patient being placed upon the table, and turned upon his left side, an incision was made, beginning at the last rib, three and a half inches from the spi. proc. vertebra, and extending downward four inches to the crest of the ileum, dividing successively the skin, areolar tissue, latissimus dorsi, serratus posticus inf., and the fascia transversalis. At this point sanious pus discharged freely, of strong ammoniacal odor, three pints of which were collected. On lengthening inner line of incision, the fingers could be readily introduced, and search was made for the kidney, which was found, after some difficulty, diminished in size, bound down by adhesions, bluish-red in color, and compressed against the posterior abdominal wall. Three openings, corresponding to the infundibula, were found leading from the convex border to the pelvis of the kidney; sinuses through which the over-distended organ had furnished an outlet to the pus contained. Repeated exploration was made by myself and the gentlemen present, but no calculus was obtained. The evacuated pus left a cavity, the measured dimensions of which were:

Upward and outward toward vertebræ..4 inches.
Upward, inward, and anteriorly.....6 "
Downward, inward, and anteriorly.....8 "

The amount of hemorrhage was slight, and no vessels required ligation.

Time occupied during operation, fifty-five minutes. The patient's condition was now so depressed that further investigation was deemed unadvisable. A pledget of oakum was interposed between lips of wound, covered with a large compress of same, over which adhesive strips were placed, and these supported by an abdominal bandage. When placed in bed his skin was blanched, and his pulse feeble and irregular.

5 P.M.—Pulse 140, temp. 98½.—Is partially conscious, but does not rally well; skin is cold, moist, and of leaden hue; he is warmly covered, has mustard over epigastrium, hot bottles to feet, and is given two ounces hot brandy.

6 P.M.—Circulation improved; says he feels more comfortable, but weak; is very thirsty; there has been no vomiting during nor since operation.

11 P.M.—Pulse 74, temperature 98½°.—Since 6 P.M. has taken ℥ iij. brandy, some beef-tea, and a glass of milk and lime-water. Skin is warm and moist, pulse more full and regular; rests upon back with ease, the first time in six weeks, and expresses himself as feeling better than last night. Has passed 12 ozs. urine, of darker color than usual. Oakum compress exchanged; drainage free; 15 ♏ Magendie's solution hypodermically to insure sleep.

March 25th, 10 A.M.—Pulse 110, temp. 100°.—Dr. Ripley present.—Passed the night in refreshing sleep, awaking only for drinks. At 6 A.M. passed ℥ viij. dark urine, containing considerable pus. Was removed from bed to table, to allow clean bedding, and cavity was thoroughly irrigated with ½ solution carbolized water, washing out pus and several blood clots; there is no offensive odor, but at orifice urinous smell still present. *Careful but thorough probing failed to discover any calculus.* Wound dressed as before.

9 P.M.—Has not had usual hectic flush this afternoon, but some sweating. Passed urine twice, ℥ viij. each time, lighter in color, and diminished deposit. Total amount of urine passed in the twenty-four hours succeeding operation, 50 ounces, of sp. gr. 1.018, acid. Has eaten some raw oysters, and drank milk punch freely. Right leg still extended and powerless. Was given 15 ♏ Magendie's solution hypodermically.

March 26th, Sunday, 10 A.M.—Pulse 110, temp. 99¼°.—Dr. C. W. Rush present.—Slept well, and feels comfortable. Aphthous spots in mouth improving. On removing dressing about 6 ozs. sanguinolent fluid escaped, with but little pus; the returned irrigating fluid was highly colored. Transudation was readily traced to the previously compressed kidney, which

was now considerably enlarged, as a result of established circulation, and oozing was taking place from its bright red granulating surface.

March 27th, 10 A.M.—Pulse 100, temp. 100°.—A single glance at the wearied expression of patient showed him to be not as well. He had slept satisfactorily, but complains of feeling worse, although he cannot define any particular distress. His skin was bluish, lips pale, nostrils dark and dry; uncovering wound the odor was fetid, and two ounces thick pus with some blood escaped. He was quickly attended to, and replaced in bed, given brandy, and soon felt much better. Temperature lowered to 99° in one hour. His depression was evidently due to deficient drainage.

March 28th, 5th day.—Pulse 110, temp. 98½°.—Dr. C. W. Rush present.—This morning had first fæcal evacuation since operation, which was composed of small, dry, hard masses (scybalous); slept two hours on left side; lies most of the time in left latero-dorsal position; eats quite heartily of meat and vegetables, and takes freely of milk punch; speaks with chest voice, and less effort; both legs drawn up unaided. Says he feels better than he has for a month, and is confident of complete recovery.

March 31st, 7th day.—Pulse 110, temp. 99°.—Dr. C. P. Tucker present.—Is doing well; has solid fæcal evacuation daily. A drainage-tube was introduced, two inches long, one inch in diameter, with flaring inner extremity and a wide fenestrated flange externally, secured by tape passing around abdomen; has an extensive miliary eruption over buttocks and abdomen.

April 4th, 11th day.—Pulse 100, temp. 98½°.—Drs. Ripley and M. J. Baker present.—Steadily improving. Is anxious to sit up in chair. Passes two pints of urine daily, free from albumen. Some pus-corpuscles still present.

April 20th.—Is gaining flesh rapidly. Has had a most voracious appetite during past two weeks. A zinc drainage-tube, of the same diameter but flattened, has been substituted, facilitating cleanliness by frequent removal. The previously displaced contents of right lumbar region have resumed their normal position. He is quite strong, and walks daily to the dining-room for meals.

April 28th.—Walks out daily, and is not fatigued; thinks he is in as good condition as he ever was. His present weight is 160 pounds. During the past four days he has gained five pounds. A small gutta-percha tube, with a perforated soft rubber tube attached, is in wound, although the amount of drainage is inconsiderable. He passes normal amount of urine daily, and several examinations have failed to reveal any element that might give rise to doubt regarding the perfect success of the means which contributed to his recovery.

May 15th.—Wound completely closed. Has returned to his work, which he pursues without inconvenience.

Remarks.—These notes were prepared for publication before I became familiar with the details of the case reported by Dr. Geo. A. Peters, in the *N. Y. Med. Journal*, Nov., 1872, with which in several particulars I thought they closely corresponded. The respective patients were males, of nearly the same age, and the right kidney the seat of disease in both cases. *Strong presumptive evidence of renal calculus—none being obtained*—and abscess affecting testicle of same side, previous to operation. As regards the openings from the convex surface to pelvis of the kidney, the amount of pus and distention was greater than in his case; had he deferred operating one week longer, the objective condition of the kidneys would have been similar. He writes of "adhesions binding it down on all sides. *Several* fluctuating points were discovered on the surface of the kidney, into one of which a small exploring trocar was introduced, and an inconsiderable amount of pus was withdrawn, but no stone was felt."

The main points of interest in this case, briefly summarized, are:

1st. The possibility of not being able to obtain calculus, when all available means of diagnosis lead one to infer its existence.

2d. The difficulty in determining previous to operation the condition of calculous, tubercular, or other varieties of pyelitus.

3d. The persistence of acid reaction of urine during the liberal administration of alkaline solutions.

4th. Preference of free incision over aspiration.

5th. The abscess of testicle; was this due to pressure upon or other interference with the function of the genito-crural nerve?

6th. The destructive changes that had taken place in the kidney, the extensive burrowing through soft parts, the relief given by operation, and the rapid convalescence.

7th. Total absence of vomiting following the administration of bromide of potassium, previous to ether inhalation, as proposed and used several years ago in the Charity Hospital.

The want of a proper nomenclature for kidney operations, which would be self-defining and readily comprehended, is much needed. The term nephrotomy might be limited to those cases when the operation by incision is undertaken with the object of relieving abnormal conditions existing within the kidney; the word itself defining the particular organ operated upon, as in cystotomy, gastrotomy, urethrotomy, etc.; while *lumbar section* would refer to the relief of conditions existing external to the kidney, and with which the organ does not enter as a complication.

I have been able to collate the following recent cases of nephrotomy:

Dr. W. W. Dawson, Ohio: female, æt. 50. Reported in *Hays' Jour.*, Jan., 1873. Death, fifth day.

Dr. Geo. W. Callender, Edinburgh. Reported in *Hays' Jour.*, Oct., 1874. Death, third day.

Dr. F. D. Lente, New York, awaiting publication. Reported "doing well."

Dr. John J. Crane, New York: male, æt. 31. Reported in MED. RECORD, Aug., 1874. Death, fifty-two hours.

My case as here recorded: male, æt. 32. March, 1876. Recovery.

The operation of extirpation of the kidney is one attended with greater difficulty, and with less chances of success, than in simple nephrotomy, as defined above. Of these I can find recorded but four cases, namely:

G. Simon, Heidelberg, 1870: female, aged 26. Reported in *Deutsche Klinik*. Recovery.

Dr. Linsen, Berlin, 1870: male. Reported in *Hays' Jour.*, May, 1872. Death, ten hours.

Dr. Durham, London, 1872: female, aged 43. Reported in *Brit. Med. Jour.*, May, 1872. Death, seventh day.

Dr. Geo. A. Peters, New York, 1872: male, aged 36. Reported in *N. Y. Med. Jour.*, Nov., 1872. Death, sixty-five hours.

Progress of Medical Science.

The Contagiousness of Whooping-Cough.—Dr. Sturges, of Westminster Hospital, recently devoted a clinical lecture, which is published in *The Lancet* of May 20th, to the consideration of the nature of the contagion in whooping-cough. He rejects the theory of specific poison, of contagion carried by a material agent, and contends that it is a nervous affection, infectious in the same way as the emotions of fear, pity, and discontent, and as the acts of yawning or laughing, or of coughing during church service. So also other nervous diseases, as hysteria, chorea, and sometimes even epilepsy, are infectious. "Catching a habit" is a proverbial expression that may often be properly applied to disease. Pertussis in a hospital does not spread from bed to bed, but skips about here and there, from one ward to another. Dr. Sturges believes that we are liable to different nervous disorders at different periods of life, and that the period of liability to whooping-cough lies between the second and sixth years of life, not spread over that time in each individual case, but falling somewhere between these limits. When whooping-cough enters a family, infants and older children generally escape, the former because they have not yet reached the period of liability, the latter because they have passed it. The whoop is notoriously recurrent as long as the catarrh accompanying it continues; relief is never permanent until the lungs are quite free and the cough gone. On the other hand, once cured it is not apt to return again, although the patient may suffer from a precisely similar catarrh. This is not because whooping-cough confers anything that prevents its return in the future, but because the human subject continues prone to the disease hardly more than two years, and when that future arrives the child has outgrown its liability. Dr. Sturges closed his lecture with the following conclusions deduced from his preceding remarks:

1. Whooping-cough is a nervous disease of immature life, due immediately, like nervous asthma, to a morbid exaltation of sensibility of the bronchial mucous membrane. Although possible in a modified form at all ages, it has its period of special liability and full development simultaneously with that time of life when the nervous system is irritable and the mechanism of respiration diaphragmatic. A child of the proper age with catarrh and cough is thus on the very brink of whooping-cough. A large proportion of such children will develop the disease for themselves upon casual provocation, all contagion and all epidemic influence apart.

2. The whoop of whooping-cough is due to a spasmodic contraction of the diaphragm which follows its extreme relaxation with the emptying of the lungs by spasmodic cough, the force of the inrush of air being met by a conservative spasm on the part of the glottis.

3. The natural history and relations of whooping-cough—its uneven course, indeterminate duration, method of recovery and cure, frequent absence of pyrexia, and seasons of prevalence—are in striking contrast with diseases of the zymotic class. Admitting the fact of its contagion, the great commonness of the disease and its association with epidemic catarrh, coupled with the popular belief that its source of infection may be indefinitely remote, are circumstances which must combine to render whooping-cough more contagious in appearance than it is in fact.

4. In its character as a purely nervous disease, whooping-cough may very well be contagious like other nervous affections of a quasi-voluntary kind. The assumption of a specific morbid poison is both hypothetical and gratuitous, or so nearly gratuitous that the facts it seems to explain are insufficient to counterbalance its inherent improbability.

5. The non-recurrence of whooping-cough is not in strictness analogous to the non-recurrence of contagious fevers, nor out of real harmony with the pattern of nervous disease. It is the rule that affections of this class alter their shape with the successive epochs of life, so that each will appear either solitary or recurrent, according as the time allotted for it is shorter or longer. The after-infancy period to which whooping-cough attaches is one of brief duration and special liabilities. The features of the disease are in strict correspondence with the characteristics of its time of life.

6. The specific remedies for whooping-cough (which have their season and may be said now to include all drugs whatever of any potency) have all of them a certain testimony in their favor. They agree in a single point: whether by their nauseousness, the grievous method of their application, or the disturbance they bring to the child's habits and surroundings, the best vaunted remedies—emetics, sponging of the larynx, ill-flavored inhalation, change of scene, beating with the rod,—all are calculated to *impress* the patient, and find their use accordingly.

A Knife-blade carried for Years in the Pleural Cavity.—Dr. Carl Bleiweis, of Leibach, reports that at the autopsy of a patient about thirty years old, who had died of pulmonary consumption on July 8th, 1875, a knife-blade was found in the left pleural cavity. It was three inches long, half an inch wide, and was lodged between the third and fourth ribs, at the inner border of the left scapula, lying in a slanting position and the edge forwards. The wound by which it had entered was indicated by a small and now adherent cicatrix about an inch above. This patient had been an inmate of penal institutions for about half of his life, and the reporter states from personal knowledge that the wound had not been received within four years of his death, and the presence of the foreign body was wholly unsuspected by those who had charge of him, the patient doubtless having reasons for not calling attention to it. Further inquiry rendered it probable that the injury was received in a quarrel in 1868 or 1869. The reporter does not regard the foreign body as the probable cause of his phthisis.—*Memorabilien, XXI. Jahr.* 20, 1876.

Treatment of Prolapsus Ani in Children.—Prof. Henoch, of Berlin, treats this affection very successfully with hypodermic injections of strychnia and ergotine. He dissolves $\frac{1}{10}$ of a grain of sulphate of strychnia in 2½ drachms of distilled water, and injects daily in the neighborhood of the anus from three to six minims—$\frac{1}{10}$ to $\frac{1}{5}$ grain strychnia. This remedy is in some cases remarkably successful, but in other cases it fails entirely. Ergotine seems to act more certainly. He injects daily a quarter, or a half, or even an entire syringeful (Pravaz's) of a solution of the strength of one to ten. The professor advises that when the child goes to stool, the chamber be arranged on a table or chair, so that the legs will hang free. This will prevent, to a great extent, the straining action of the abdominal muscles.—*Allgemeine Medicinische Central Zeitung*, May 31st, 1876.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, July 22, 1876.

BAXTER'S STATISTICS.*

It should be a matter of congratulation with statisticians and medical men generally that the examinations of recruits and drafted men during the late rebellion are now made available for scientific study. We are hardly surprised, in view of what we have seen done by the army medical bureau at Washington, to find the work of Colonel Baxter the most complete of its kind that has ever been published. Two immense quarto volumes are before us, filled with figures, charts and maps, systematizing and elaborating the anthropological and medical conditions of nearly a million of men who were examined for admission in the late army of the rebellion. These examinations were made by authority of the different States furnishing the recruits, but they were generally found to be so unsatisfactory in their results, owing to a want of uniformity of system and centring of responsibility, that Congress passed an act in March, 1863, creating a bureau of the War Department, known as that of the Provost-Marshal General's. A complete enrollment of all the States was then made; and in order that none but able-bodied men should be placed in the field, a medical branch of the Provost-Marshal's Bureau was established, and to it was assigned the authority and responsibility of thorough and systematic medical examinations. This medical bureau was placed in charge of Col. J. H. Baxter, from its inception to the end of the war. The great value of the statistics which had been collected during that time was then prospectively presented in a "report of the medical statistics on file," and the impression made upon the government was such that Col. Baxter was directed to continue his labors and make a complete report. Under the system adopted by him and carried out by the surgeons of the boards of enrollment, a most complete systematic account of every individual examined was obtained. To give some idea of the comprehensiveness of the plan, it is only necessary to refer to the fact that in the blanks furnished to examiners the following conditions were to be noted concerning each recruit or drafted man: Date of examination, designating number, name, age, nativity, occupation, height, complexion, color of eyes, color of hair, girth of chest at inspiration and expiration, social condition, color, general physical constitution or physique, whether a volunteer or substitute, result of examination, specification of disease when rejected, and if accepted, the noting of any distinguishing natural or accidental mark by which the recruit might be identified. In fact the proper filling up of this blank gives the physical likeness of the individual examined, and constitutes an accurate and thoroughly trustworthy descriptive list.

The intrinsic value of the statistical data not only rests upon the circumstances of its uniform and systematic detail, but also upon the fact that the examinations represent the mean condition of the people as a whole, every class being well represented, either in the wide-spread offering of volunteers or in the accident of a general draft.

In order to make the comparison of each of the physical conditions with the others noted, easily comprehended, the plan of giving ratios expressing the relation that one number bears to another has been adopted, and as these ratios are millesimal, their simplicity and accuracy can scarcely be questioned. The labor in calculating these ratios, considering the different and multitudinous comparisons to be made, has been, as might have been expected, immense. Col. Baxter makes the following statement in regard to this point, which is full of significance as an earnest of his intention to make the deductions of his figures valuable: "The labor of computing all these ratios has of course been very great; over a hundred and thirteen thousand calculations, in which the decimal was carried out four places, having been made and carefully verified by the ordinary method, and by the addition of the results obtained, which, if correct, would agree with a larger ratio obtained in another way." He further says: "For convenience in estimating, the tables may be put into six classes, as follows: the first class consisting of Tables 1, 2, and 3; the second of Tables 4, 5, 6, 7, 8, and 9, the third of Tables 18, 19, and 20; and the sixth of Tables 21, 22, and 23. To produce the tables of the first class in their present form, three thousand five hundred *preliminary* tables had to be made. These preliminary tables contained, in the aggregate, three million five hundred thousand sets of figures, or independent num-

* Statistics, Medical and Anthropological, of the Provost-Marshal-General's Bureau, derived from Records of the Examination for Military Service in the Armies of the United States during the late War of the Rebellion, of over a Million of Recruits, Drafted Men, Substitutes, and Enlisted Men. Compiled under direction of the Secretary of War, by J. H. Baxter, A.M., M.D., Colonel and Chief Medical Purveyor U.S.A., late Chief Medical Officer of the Provost-Marshal General's Bureau. In two Volumes. Washington: Government Printing Office. 4to, pp. 1165.

bers, and were condensed into twenty-four intermediate tables—one for each nativity—which contained one million four hundred and forty thousand sets of figures, exclusive of eleven thousand ratios; and these twenty-four intermediate tables were condensed to form Tables 1, 2, and 3, and presented in this report."

Although the statistics of the tables is comparatively easy of comprehension by the ratios given, even the mere mental comparison of abstract numbers is made unnecessary by the arrangement of charts, which present, by horizontal tinted columns of different lengths, a ratio of difference corresponding to the proportions per thousand as expressed in the figures. In addition to these charts showing the comparative anthropological and medical conditions of the men examined, we have beautiful maps, differently colored, and graded in shade to picture the prevalence of different diseases in the different Congressional districts. This may be called scientific object-teaching on a large scale, and will constitute the most interesting and valuable feature of the work for the ordinary student of anthropology, giving the general conditions, physical and regional, which are associated with the prevalence of disease in this country.

Any attempt at an extended analysis of the conclusions to be drawn from the immense array of statistical facts presented in these ponderous volumes, would be, of necessity, incomplete; but we shall try, in a cursory way, to present a meagre outline of the ratio of disease to occupation, and to social and physical conditions, leaving the gaps to be filled up by the patient study of those who are interested in these kind of investigations.

In order to avoid unnecessary repetition, we shall name in order the ratio of disease as connected with the different conditions named, giving three of the highest grades in each. For instance, the chart of General Diseases in connection with occupation, the highest ratio is represented by the following in the order named: (1) Editors, (2) Teachers, and (3) Watchmen. This plan of enumeration being understood, we present it in abstract under the respective headings:

General Diseases as to locality: (1) Massachusetts, (2) Maine, (3) Rhode Island. Nervous diseases, as to locality: (1) Rhode Island, (2) New Hampshire and Connecticut. In the consideration of the highest ratios of special diseases in the different States we also express them in numerical order:

Phthisis pulmonalis.—(1) Maine, (2) New York, (3) Connecticut. *Paralysis.*—(1) New Hampshire, (2) Maryland, (3) Rhode Island. *Insanity.*—(1) New Hampshire, (2) Rhode Island, (3) Maine. *Hernia.*—(1) Minnesota, (2) Rhode Island, (3) District of Columbia. *Syphilis.*—(1) Rhode Island, (2) District of Columbia, (3) Maryland. *Diseases of the Eye.*—(1) Missouri, (2) Illinois, (3) Massachusetts. *Diseases of the Ear.*—(1) Minnesota, (2) Maryland, (3) Massachusetts. *Diseases of Respiratory Organs.*—(1) Rhode Island, (2) Connecticut, (3) Massachusetts. *Diseases of Digestive Organs.*—(1) Minnesota, (2) Massachusetts, (3) Vermont. *Diseases of Circulatory System.*—(1) Maine, (2) Rhode Island, (3) Massachusetts. *Diseases of the Organs of Locomotion.*—(1) Maine, (2) Massachusetts, (3) New Hampshire. *Diseases of Urinary System.*—(1) Massachusetts, (2) Maine, (3) Connecticut. *Diseases of Generative System.*—(1) Massachusetts, (2) Maine, (3) Rhode Island. *Diseases of Cellular Tissue.*—(1) Rhode Island, (2) Massachusetts, (3) Maine. *Diseases of Cutaneous System.*—(1) Illinois, (2) Missouri, (3) Minnesota. *Local Injuries.*—(1) Maine, (2) Delaware, (3) Missouri. *Internal Organic Diseases.*—(1) Missouri, (2) Kentucky, (3) Illinois. *Diseases and Injuries of Nose.*—(1) Maryland, (2) Delaware, (3) Minnesota.

In regard to the social condition, the married men showed the highest ratio of disease of every class except syphilis. The reason for this undue preponderance of diseases is probably owing to the fact that the very large majority of volunteers and drafted men were at that age in which matrimony was the rule rather than the exception.

In regard to the influence of occupation upon the different diseases we have the following remarkable exhibit:—

Chronic Rheumatism.—1. Liquor Dealers; 2. Photographers; 3. Brokers. *Syphilis.*—1. Sailmakers; 2. Cooks; 3. Paper-hangers. *Phthisis Pulmonalis.*—1. Editors; 2. Dentists; 3. Architects. *Diseases of Nervous System.*—1. Watchmen; 2. Agents; 3. Innkeepers. *Paralysis.*—1. Agents; 2. Architects; 3. Physicians. *Mental Diseases.*—1. Coppersmiths; 2. Ostlers; 3. Engravers. *Diseases of the Circulatory System.*—1. Liquor Dealers; 2. Coppersmiths; 3. Editors. *Obesity.*—1. Sailmakers; 2. Photographers and Innkeepers. *Diseases of Digestive Apparatus.*—1. Watchmen; 2. Innkeepers; 3. Merchants.

The relative ratio of these diseases to the respective profession is of more or less interest to medical men, as showing the comparative healthfulness of their calling. We name the professions in the order of their ratio of influence upon disease, and in this instance, for the sake of more extended comparison, will give the complete list as presented in the chart.

Chronic Rheumatism.—1. Lawyers; 2. Public Officers; 3. Physicians; 4. Clergymen; 5. Druggists; 6. Dentists; 7. Teachers; 8. Students. Architects, Editors, and Musicians, *nil.* *Syphilis.*—1. Musicians; 2. Architects; 3. Druggists; 4. Public Officers; 5. Physicians; 6. Clergymen; 7. Students; 8. Dentists; 9. Teachers; 10. Lawyers. Editors, *nil.* *Phthisis Pulmonalis.*—1. Editors; 2. Dentists; 3. Architects; 4. Public Officers; 5. Physicians; 6. Teachers; 7. Clergymen; 8. Lawyers; 9. Druggists; 10. Students; 11. Musicians. *Diseases of Nervous System.*—1. Lawyers; 2. Clergymen; 3. Physicians; 4. Druggists; 5. Public Officers; 6. Architects; 7. Teachers; 8. Mu-

sicians; 9. Students; 10. Dentists; 11. Editors, *nil*. *Paralysis.*—1. Architects; 2. Physicians; 3. Lawyers; 4. Teachers; 5. Druggists; 6. Public Officers; 7. Clergymen. Dentists, Editors, Musicians, and Students, *nil*. *Mental Diseases.*—1. Lawyers; 2. Clergymen; 3. Musicians; 4. Physicians; 5. Students; 6. Druggists; 7. Teachers. Architects, Dentists, and Editors, *nil*. *Diseases of Circulation.*—1. Editors; 2. Physicians; 3. Public Officers; 4. Clergymen; 5. Architects; 6. Lawyers; 7. Teachers; 8. Druggists; 9. Dentists; 10. Musicians; 11. Students. *Diseases of the Digestive Apparatus.*—1. Dentists; 2. Physicians; 3. Editors; 4. Public Officers; 5. Clergymen; 6. Druggists; 7. Lawyers; 8. Architects; 9. Teachers; 10. Musicians; 11. Students. *Obesity.*—1. Lawyers; 2. Dentists; 3. Musicians; 4. Students; 5. Clergymen; 6. Physicians; 7. Teachers. Architects, Druggists, Editors, and Public Officers, *nil*.

As we have before remarked, it is impossible, in an ordinary editorial notice, to give even an outline of the valuable deductions contained in these wonderful volumes, but we have striven to perform a conscientious duty in presenting what we have to our readers, in order that they may obtain a faint idea of the immense and incalculable value of this elaborate contribution to the systematic study of the statistics of disease, and their connection with the interesting subject of anthropology. With such a work before the faithful student of statistics, political economy, and public health, it is impossible to say what will be the limit of his studies in the mysteries of the natural laws of development and disease.

In conclusion, we congratulate Col. Baxter on the completion of his arduous labors, and in the name of his profession thank him for the present benefit and prospective good which such labors have conferred upon them.

Reports of Societies.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, May 24, 1876.

DR. C. K. BRIDDON, PRESIDENT, IN THE CHAIR.

RUPTURE OF THE BLADDER.

DR. ERSKINE MASON presented a specimen of rupture of the bladder taken from a man aged thirty-two years, who was admitted into Bellevue Hospital on May 13. On the tenth of May the patient was arrested for intoxication, and was confined in a station-house. Shortly afterwards he complained of inability to pass his water; and, suffering from great pain in consequence, he applied for relief. Instead of obtaining assistance, however, he was deluged with cold water. On the following day he was taken to the City Prison (Tombs), where he remained until his admission to the hospital. While at the prison his water was drawn twice.

When Dr. Mason saw him at the hospital he was perfectly rational; had a small, feeble pulse, anxious countenance, and the abdomen was swollen, the upper portion being tympanitic and the lower portion dull. He complained only of vesical tenesmus. The scrotum was somewhat discolored, giving rise to the possibility of injury of the perineum and consequent rupture of the bladder. No other marks of external injury were, however, discoverable. A moderate-sized catheter was passed into the bladder, and twenty ounces of pure urine were evacuated. There was evidently no stricture. A rectal examination was made by passing the forefinger well up into the rectum, behind the prostate. A little to the left of the latter a distinct swelling was recognized, containing fluid. The diagnosis was then made of rupture of the urethra, behind the triangular ligament, with effusion into the peritoneal cavity.

As the only hope rested in an operation, the usual one for lithotomy was performed. As soon as the incision was made, the finger being passed into the bladder, came in contact with, and passed through, a rent into the posterior wall of the viscus. The latter was firmly contracted, and no urine flowed through the incision. A silver catheter was then passed through the rupture into the peritoneal cavity, and ten ounces of a somewhat turbid fluid were drawn off. The patient sank and died twelve hours after the operation, and on the fourth day from the commencement of the trouble. The autopsy was made a few hours after death, and revealed general peritonitis, with considerable urine in the cavity of the abdomen. The intestines were matted together by recent adhesions. In the posterior wall of the bladder the rent was discovered, measuring one and a half inches in length, the edges being everted, and presenting a sloughy appearance.

In conclusion, Dr. Mason gave the following statistical account of the operations which had been performed for rupture of the bladder:

"The first who did this operation for rupture of the bladder was Dr. W. J. Walker, of Boston, 1845. Operation done 24 hours after the accident; patient recovered.

It was done in this city by Dr. Willard Parker, a few hours after rupture had occurred; patient recovered.

I have had four cases of rupture of the bladder, where I did this operation, and two recoveries.

My first case was in 1871, and reported in the *N. Y. Journal of Medicine*, in a paper on rupture of the bladder, August, 1872.

The first case I had was in 1871. Operation done third day after the accident; patient recovered.

Second case in 1873, a few hours after the accident; patient recovered. Third case was operated on twenty days after the accident; he lived fourteen days. Reported in the MEDICAL RECORD for Dec. 1, 1874. Fourth case, just reported."

I have been able to collect seven cases where this operation has been done, and with four recoveries, a most gratifying result when compared with the seventy-eight cases of rupture of the bladder collected in 1851 by Dr. Stephen Smith, which were treated without operation. Among these there were but five recoveries, and but in one had the rupture opened into the peritoneal cavity, and but in three was the rupture due to violence.

MONTHLY ABORTIONS.

DR. MARY PUTNAM JACOBI presented a small specimen which had been discharged from the uterus of a

married lady during one of her monthly periods. As similar masses, partly resembling clots, and partly resembling membranes, had been voided every month, and as the patient was always regular in her catamenia, she was supposed to be suffering from simple dysmenorrhœa. The passage of the clot, as is usual on such occasions, was always accompanied with pain. The microscopic examination of the specimen in question showed the existence of flat epithelial cells imbedded in a very fine matrix, but none of the cylindrical cells of the uterine cavity were found. The clot was then carefully washed, when the appearance of a very minute blood-stained embryo was seen, with head, neck, extremities, and umbilical cord. The doctor believed that this product of conception had been destroyed by hemorrhage as soon as formed, and thought it by no means impossible that the previous attacks of dysmenorrhœa could be explained in a like manner; in other words, that the patient had been in all probability suffering from monthly abortions.

Dr. Peugnet presented three specimens. The first was the caput coli and appendix vermiformis removed from a young man aged nineteen years. On Monday (May 24) not feeling well he concluded to consult a physician. In his attempt to get into a carriage for that purpose he was seized with syncope, followed by peritonitis and death. At the autopsy the appendix vermiformis was found very much distended with fæces, with a rupture near the cæcum. No enterolites were discovered.

IRREDUCIBLE FEMORAL HERNIA.

Dr. Peugnet presented a second specimen, which was one of irreducible femoral hernia.

On the 22d of December, 1875, the Doctor saw the patient in consultation with Dr. Naudain: a lady, 68 years of age, during her first pregnancy, at 23 years of age, contracted a femoral hernia on right side; this was reduced by her physician and controlled by a triangular pad and bandage, as a truss was irksome. She continued to enjoy good health until about six years since, when she began complaining of intense enteralgia, spasmodic in its character, accompanied with nausea, vomiting, and obstinate constipation; she was seen by several physicians, who made the usual diagnoses in such cases, especially as no evidences of hernia could be found, although carefully searched for. Her enteralgia was controlled by opiates, the constipation only relieved by croton oil, and even this occasionally failed. On the 21st of December, 1875, whilst at stool, a tumor made its appearance in her right femoral region, which led to a recurrence and aggravation of her symptoms. Several attempts were made to reduce the femoral hernia, but without success. The Doctor found the swelling about the size of a hen's egg. As it was evidently distended with serum, an ounce of amber-colored fluid was removed by aspiration; a loop of intestine could then be distinctly felt, but still remained irreducible. Dr. Peugnet then made the usual incision, exposing the sac, and without opening it, divided Hey's ligament and reduced the hernia without difficulty. During the night, the patient had, as she expressed it, "the first natural movement from her bowels in years." On the fifth day there was a recurrence of her pain and nausea with constipation, but these subsided under appropriate treatment. On the 11th day she insisted upon rising for stool, immediately sank into collapse, and died in twelve hours. At the post-mortem, 24 hours after death, the most extensive diffuse suppurative peritonitis was found, although there had not been the slightest indication of it previous to her death. A diverticulum of the ileum was found protruding through the right femoral ring adherent to the sac, and firm and old adhesions were also found at the neck; immediately above, the ileum was twisted, and the entire small intestine above the twist distended with fæcal matter. It was evident that the hernia reduced by the operation was a recent enterocele, and that the adherent intestine served to explain the causation of the severe and obscure gastro-intestinal disorders this patient had been subject to at intervals for several years previously.

OVARIOTOMY.

A third specimen by Dr. Peugnet was an ovarian cyst, with the following history:—

Mrs. H., æt. 70 years 9 months, a multipara, had always enjoyed good health until January, 1875, when she felt a sensation of discomfort and uneasiness in the lower portion of the abdomen; but did not observe any appreciable enlargement until the ensuing April; then sought medical advice, and was treated with diuretics. Subsequently she passed into the hands of a homœopath, who pronounced it a uterine fibroid and treated her for inflammation of the bowels in consequence thereof, and pronounced her case as incurable. Dr. Naudain was finally called in, and recognized the difficulty.

On the 11th of March, 1876, Dr. Peugnet saw her in consultation with Drs. Naudain and the late C. F. Rodenstein. The abdomen was much enlarged and the physical signs of an ovarian cyst unmistakable. With a view to relieve her from the pain and distress caused by the pressure, as well as to prepare her for ovariotomy, the Doctor tapped the cyst, and removed from it twelve pounds of a clear albuminous fluid. The uterus, which was turned towards the right iliac region, and partially anteverted, immediately resumed its natural position; no evidences of adhesions were found, and there were apparently some solid constituents in the cyst which evidently arose from the left side. On the 15th of March the patient was taken with symptoms of peritonitis, which, at first alarming, rapidly subsided under the use of opiates. Owing to her advanced age, she was advised that ovariotomy was scarcely warrantable, but insisted upon submitting to it rather than to suffer a year or two longer. With this view, quinine, muriated tincture of iron, with minute doses of the bichloride of mercury, were administered to her, the latter with the special purpose of increasing the red corpuscles of the blood, as she was rather anæmic.

On the 3d of May, the patient having been etherized by Dr. A. M. Campbell, Dr. Peugnet, with the advice and assistance of Dr. Sims, and in the presence of Drs. Naudain and Crump, performed the usual suprapubic operation. There was a slight effusion of serum in the peritoneal cavity, a few adhesions on the left anterior surface, which were readily separated with the fingers, the cyst evacuated with the dome trocar, and readily extracted, the pedicle secured with wire clamp, and a rubber drainage tube passed through Douglas's cul-de-sac. This tube had been prepared by Dr. Sims, and was constricted at its centre by means of a silver ligature, for the purpose of permitting of a more thorough washing out of the peritoneal cavity, the injection passing in from above, and the drainage portion proper carrying it off from below. For the purpose of insuring perfect drainage, the straight portion of a silver catheter, of sufficient length to reach the bottom of the pelvic cavity, was passed into the upper extremity of the tube. One of the adhesions was tied with a silk ligature, and the latter cut close. The wound closed with twelve silver sutures, all passing through the peritoneum. The cyst and contents

weighed over twenty pounds. One hour and fifty minutes, including anæsthesia and dressing the patient, was consumed in the operation. Pulse 106, temperature 98° in axilla, immediately before the operation. Drainage in first twenty-four hours, two ounces of bloody serum, none subsequently. The pulse never rose above ninety-eight, temperature 99⅘ in mouth. On the 5th, or second day, there was slight tympanites and tenderness, which entirely subsided on the 7th, or fourth day. Ten sutures were removed on the 10th, also the silver tube. On the 11th, or eleventh day, the drainage tube was removed; 19th, or sixteenth day, the pedicle came away; 20th, an enema, followed by an evacuation; 24th, or twenty-first day, patient sitting up, a small superficial ulcer at lower segment of wound.

The special points of interest in this case, are, 1st, one of the oldest recorded; 2d, the rapidity of the development of the cyst, which is multilocular, but only one having attained any size.

TRACHEOTOMY IN DIPHTHERIA, IN A BOY TWO YEARS ELEVEN MONTHS, WITH RECOVERY.

Dr. Charles A. Leale presented two pieces of diphtheritic membrane, each over two inches in length, which he had removed from the opening in the trachea, on March 22, 1876. The child had adenitis, œdematous face and neck, was cyanotic, and suffocating from the accumulations of exudations in the larynx and trachea, when Dr. Leale made an opening as low as the upper border of the manubrium, while the child was additionally rendered insensible by sulphuric ether. No vomiting followed, no blood-vessels were ligated, and only about ʒ ij. of hemorrhage lost from the capillaries. It was nearly an hour before the tube could be safely inserted, in consequence of the large accumulation of muco-purulent matter and diphtheritic membrane, which he removed by the long elbow forceps inserted through the wound, and while the child was held with head lower than body to facilitate the removal of matter, by sponging the parts immediately after an expiration, and before it could be drawn in by returning inspiration. In two hours after the operation the child breathed comfortably, and the skin was less cyanotic; he was placed on his side, and inhaled steam; and Dr. J. Lewis Smith in consultation saw him. At 12 P.M. Dr. Leale examined a piece of the freshly thrown off membrane, and found it alive with cocco-bacteria. First day after operation, child breathed easily through the tube; the inner one removed every half hour to be cleansed—it frequently containing large pieces of the diphtheritic membrane. During a forcible paroxysm of coughing, a piece was thrown through tube a distance of ten feet. Second day, pulse 120, R. 35, no air could pass through the larynx, and the endeavor increased the painful breathing to an alarming degree. Third day, P. 135, R. 35, T. 105°; profuse expectoration through tube, and frequently clots of blood. Urine examined within quarter of an hour after being voided, contained ½ albumen, epithelial casts, and an abundance of living bacteria. Seven P.M. P. 144, R. 62, T. 106°, increased evidences of septic poisoning. Nine P.M., P. 135, R. 60, T. 105°; erosions around wound, and from pressure of tube, caused 1 oz. hemorrhage; and, in consequence, the tube was permanently removed; has very painful cough and profuse expectoration of thick diphtheritic membrane from the small bronchial tubes.

4th day: P. 150, R. 60, T. 105°; entire surface of body covered with herpes, profuse diarrhœa, very light in color, and containing large quantities of mucous and diphtheritic membrane, showing that the disease had extended to the stomach.

5th day: P. 130, R. 28, T. 102⅘°; wound in neck covered with diphtheritic exudation, which reforms as soon as removed by suppuration.

6th day: P. 140, R. 62, T. 105⅗°; cannot breathe through the larynx; two small deep seated abscesses opened beneath the fascia at wound, discharging about ½ oz. pus; child exceeding fretful; passage of air over denuded bronchial membrane very painful; parts cleaned by frequent sponging after expirations, wound contracting, and child becoming cyanotic in consequence. With the elbow-forceps passed a small piece of sponge rapidly two inches through the opening, at moment of inspiration, and with forceps dilated the tracheal opening with beneficial effect; and concluded, if no improvement followed, to reinsert the tube.

7th day, by cleansing the wound to keep it open, and with partial removal of occlusions above, by coughing, could breathe better. There is complete aphonia.

From 7th to 11th day after the operation, the pulse, temperature, and respirations at many times were alarming; and apparent death impending. After the 11th day, convalescence fairly commenced and rapidly progressed until April 13th, twenty two days after the operation, when he went to Dr. Leale's office. The opening had then completely closed, and the voice was almost entirely restored. His treatment from time of operation until recovery was without any medicine. Diet of milk, bread and water, and the inhalation of steam in a room, the temperature of which was kept at 98° Fah.

Dr. Mary Putnam-Jacobi, in referring to the successful result of the operation in so young a child, asked the question if there were any similar cases on record of children under one year of age.

Dr. Beverley Robinson answered that Dr. J. Solis Cohen, in his late work "*On Croup* and its Relations to Tracheotomy," had reported several of such cases.

Dr. Robinson has since then sent the Secretary the following statistics from the work referred to:—

Age at Operation.	Operator.
6 weeks	Scoutetten (Strasbourg), 1840.
7 months	Bell (Edinburgh), 1861.
7 months	Lawson Tait (Birmingham).
10 months	Baizeau (Algiers).
10 months	Dujardin.
10 months	Bourdillat.
10 months	J. Cooper Forster.

The details of the first of the above cases (which are very remarkable), will be found in the *Am. Jour. Med. Sciences*, April, 1844, p. 466.

Dr. Mason thought that the elbow-forceps spoken of by Dr. Leale was an invaluable instrument for the removal of phlegm from the trachea, and he was satisfied that he had by its use saved more than one child's life. The sudden plugging of the tube was an accident of such frequency, and so often resulted in death before the physician could be summoned, that his experience had almost persuaded him not to use a tube at all, but merely to make a free incision, keeping the lips of the wound open by strings passed behind the neck. The objection to the old form of tube was that, by unequal pressure at its curve, it produced ulceration.

Dr. Robinson thought that this complication could be avoided by use of the tube bent at right angles.

In answer to a question regarding the laying open of the tracheal wound, Dr. Mason stated that such an operation had been performed abroad.

Dr. Bridson added his testimony to the great value of the elbow-forceps in the prompt and efficient removal of clogging phlegm in the trachea, and referred to some cases in which it had proved the only means

of saving life. In one instance of tracheotomy for syphilitic disease of the larynx he was in the habit of cleaning out the trachea regularly with this instrument, sometimes inserting it as far down as the bifurcation, which latter, on more than one occasion, was grasped between the blades. In order to guard against the possibility of plugging of canula, he had made it a rule to have the inner tube removed every hour, washed and immersed in glycerine before it was reinserted. In regard to the propriety of the operation he had not the slightest doubt, and believed that it was not performed as often as it should be. He was of the opinion that the use of anæsthesia during the operation would explain a good many fatal results.

Dr. Mason, in connection with the danger of sudden clogging of the tube, referred to a case of his in which tracheotomy was performed as a forlorn hope, and in which at the moment of its completion a plug of mucus was coughed into the tube, completely closing it and causing immediate death.

Dr. Biddon presented the ankle-joint removed by amputation of the leg from a male patient of the Presbyterian Hospital. He then read the following history of the case as prepared by Dr. W. E. Forest, a member of the House Staff:

Terrence Reynolds, age 34, admitted February 23d. Three months ago the patient was pushed backward off a step, striking on the left foot and falling to the ground. Admitted to the hospital next day for fracture of the leg. The patient is a large man, of intemperate habits. Had syphilis fifteen years ago, followed by secondary and tertiary manifestations.

On examination the tibia was found to be fractured near the ankle, obliquely downwards and forward into the joint. The fibula fractured at the lower extremity as in Pott's fracture. The soft parts presented no appearance of injury except *a small superficial abrasion*, so small as almost to escape detection, opposite the lower end of the tibia. The syphilitic cachexia of patient was strongly marked, the integument over the tibia on the uninjured limb being purplish and scaly, and deformed by ostitis and periostitis.

Three days after admission the limb was put up in a plaster dressing. In a few days this was removed, when the small abrasion at the anterior and inner side of the ankle was found to have assumed the circular, worm-eaten appearance of a syphilitic ulcer. The plaster dressing was reapplied, a fenestra being cut in the dressing opposite the ulcer, and the patient put upon anti-syphilitic treatment.

From this time, March 1st, the ulcer steadily progressed, in spite of treatment, until it became nearly an inch in diameter, of a circular, perforating character.

March 27th.—The patient had a severe chill, followed by some prostration, during the past night. The discharge to-day is greater in amount, and movement of the foot forces out a thin, sanious pus. The chill, together with the character and manner of the discharge, indicates, it is thought, that the joint is penetrated.

March 29th.—The probe passes into the joint and comes in contact with carious bone. A small detached fragment of necrosed bone from the lower end of the tibia was removed. The surface of the ulcer has assumed a diphtheritic appearance.

April 2d.—An incision made in front of the external malleolus allowed a free discharge of pus. From this time on the discharge continued from both the openings into the joint; the lateral motion of the foot became more and more marked, and crepitus on movement of the foot was distinct; water injected into one opening passed freely through the joint and out at the other opening. Thus a simple abrasion of the skin had become a penetrating ulcer of the ankle-joint, due to the syphilitic cachexia of the patient.

May 5th.—The condition of the joint has not greatly changed. The blackened and necrosed end of the tibia is visible through the inner opening, and caries of the astragalus can be detected by manipulation. The integument of the whole lower third of the leg has assumed an unhealthy, brawny, inflamed appearance.

May 11th.—Amputation having been decided upon, the operation was made at the junction of the upper and middle thirds of the leg, by the lateral skin flaps and circular through the muscles. A small quantity of blood was lost and the patient made an excellent recovery from the immediate effects of the operation. The examination of the amputated part showed the periosteum covering the lower end of tibia to be thickened and inflamed. The posterior half of the articular surface of the bone was split off, together with the posterior two inches of the lower end of the bone. The anterior portion of the articular surface and the anterior portion of the bone at its lower end was dead and blackened, but no well-marked line of demarcation had formed. The posterior portion of the lower end of fibula fractured off and displaced. The astragalus was extensively ulcerated and eroded on its upper surface. The remaining bones of the foot healthy.

Correspondence.

THE THEORY OF ANIMAL HEAT.

To the Editor of The Medical Record.

Sir:—Allow me to intrude upon your space in order to speak of some theories advanced by Dr. Gray, of West Meriden, Conn., in his article on "Animal Heat, and its Reduction by the use of Gelsemium."

I shall not at all refer to his discovery of the febrifuge quality of the herb spoken of, although I am quite a sceptic from the experience I have had. For in my own experience, as well as in that of several colleagues, I have seen the much-vaunted febrifuges, such as quinia, salicylic acid, as well as salicylate of soda, prove utterly unable to control a high febrile state in many cases. In others their administration has been followed by a reduction—in some cases a marked one—and there the golden rule, "*Post hoc ergo propter hoc*," has, of course, been applied.

Notwithstanding, I shall try the gelsemium as faithfully as I have tried the others, and I am really sorry that for that reason Dr. Gray's paper has come only now to my notice.

The only reliable and never-failing method has been, at my hands, that of Ziemssen—lukewarm baths, gradually reduced to a cold temperature. In pneumonia, of children especially, if combined with one or two doses of quinine—given more as a tonic than as a febrifuge—they are invaluable.

Be that as it may, however, the point I wish to make is one that has a wider application: I propose to speak of Dr. Gray's "*full and rational theory of heat*," which he gives in the following words:

"An increase or diminution of the activity of the vital functions is accompanied by a corresponding rise or fall of the temperature of the body."

I shall not ask Dr. Gray how he reconciles that clini-

cally so important variety of fever, called asthenic, with this theory, or whether he recognizes such a type at all; I only wish to direct his attention to the term vital functions.

This term, as well as vital force, ought to be entirely discarded. In modern physiology the principal effort has been directed toward showing that in the animal, as well as in the vegetable kingdom, the same physical and chemical forces are the active agents; and although force, as well as motion, may take different forms, there is one and the same impulse underlying them all. Force is the cause of motion, and motion is the cause of force; potential energy may, in various ways, be stored up and transformed into actual energy, and a given amount of the one will always correspond to a definite amount of the other. This theory of the correlation of forces applies to vital, so-called, as well as to physical or chemical forces. And the explanation of the process by which animal heat and muscular power is developed is the following:

In the leaf of the plant, which is the chemical laboratory in the earth's household, the granules of chlorophyll have the innate property of deoxidizing carbonic acid under the influence of the sun's light (the yellow rays particularly). The process takes place in presence of various inorganic bodies, such as water, ammonia, sodium, and potassium salts, sulphuric and phosphoric acids. These may enter in combination with some of the reduced carbonic acid atoms and form various albuminous bodies; or, if water alone enters, or its constituents, hydrocarbons and carbohydrates will result. Only a comparatively small part of these compounds is used up for the tissue-change of the living plant, undergoing oxidation and leaving it again in the form of carbonic acid. The greater part remains and serves as nutriment to animals, in whose bodies it is oxidized and nearly all of it reconverted into carbonic acid and water; only a small part of the nitrogenous compounds is not completely oxidized and leaves the system as urea, and is then transformed into a carbonate of ammonia, ready again to begin its cycle.

The principle of the correlation of forces teaches that every particle of the force developed by the sun's light in deoxidizing the CO_2 in the chlorophyll-granules of the leaf is deposited as actual energy in the carbon-compounds resulting from this process. This potential energy is converted into actual energy as soon as the carbon contained in those vegetable matters is brought to its highest degree of oxidation, *i.e.*, is burnt up to CO_2. The actual energy thus produced by chemical action may directly take the form of molecular motion, of heat, or a part of it may be converted into mechanical motion by the intermediary stage of muscular contraction.

Vital action, therefore, means nothing but *chemical action*, however modified by the circumstances under which it takes place. Animal heat has its source in nothing but in chemical action; however modified the oxidation, however numerous the intermediary stages (Gorup-Besanez mentions about ten of the latter), it is *oxidation*, and nothing but *oxidation*.

The explanation of animal heat by "friction and vital force" is utterly untenable in the light of modern physiology, and besides it is not even the only theory held by physiologists of the seventeenth century, as Dr. G. stated; for there lived during that time a physician in Bath, England, by the name of John Mahew, whose views, as published in his works, in 1683 (two years after his death), very nearly conform with the principles heretofore stated, which are accepted by all the great physiologists of the day.

If friction is really to take part in the production of animal heat (and to a very limited degree it does), we may well ask, What is the cause of the friction? The answer is the expulsive force of the heart. And the cause of this force? The contraction of the heart-muscle. And of this? Well, nothing but the oxidation of the constituent muscular tissue and muscle plasma. Therefore *oxidation* again is the *ultimate* and the *only* cause of animal heat. And this same oxidation that is the cause of the tissue-change, gives, to my mind, a much more rational explanation why the blood in the veins is warmer than in the arteries, especially that of the portal vein, which collects the blood from the most extensive mucous membrane of the body, where, naturally, absorption and chemical action is at its height. It is hardly probable that the impelling force of the heart should be of such magnitude as to produce an elevation of the temperature of the blood by friction, amounting to ½ to 2 degrees. On the contrary, as Fick has shown, the mechanical work of the heart in 24 hours is equal to 40,000 kilogrammometers, which is equal to about 100 units of heat, *i.e.*, the force of the heart, if entirely converted into heat, would be able to raise the temperature of 100 kilos of water by 1° C. (=1¾° F.). Assuming the amount of blood in a man to be 9 kilos, and his pulse to beat 60 in a minute, a simple calculation will determine the elevation of temperature for every beat:

$$\frac{9 \times \qquad \times 100}{5 \times 24 \times 60 \times 60 \times 9} = 0.0000231 \text{ F.},$$

and not from ½° to 2°, as Dr. Gray's theory assumes.

Friction and *vital functions* ought therefore to be put aside, and *oxidation* take its place.

Yours truly,

GEO. W. RACHEL, M.D.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from July 9th to July 15th, 1876.

COUES, E., Asst. Surgeon. To report to Secretary of the Interior for duty with the U. S. Geological and Geographical Surveys of the Territories, under charge of F. V. Hayden, U. S. Geologist. S. O. 134, A. G. O., July 3, 1876.

KNICKERBOCKER, B., Asst. Surgeon. His resignation accepted by the President, to take effect July 1, 1876. S. O. 134, c. s., A. G. O.

CLEMENTS, B. A., Surgeon. Assigned to duty as Post Surgeon at Fort Sanders, Wy. T. S. O. 92, Department of the Platte, July 7, 1876.

TILTON, H. R., Assist. Surgeon. On completion of examination for promotion, to proceed to Headquarters, Department of Dakota, and report to the Medical Director of that Department. S. O. 138, A. G. O., July 10, 1876.

KINSMAN, J. H., Assist. Surgeon. When relieved by Dr. Terry, to proceed without delay from Fort Ripley, Minn., to Fort A. Lincoln, D. T., for temporary duty at that post. S. O. 83, Department of Dakota, July 12, 1876.

CALDWELL, D. G., Assist. Surgeon. Leave of absence extended two months. S. O. 137, A. G. O., July 8, 1876.

BENTLEY, E., Assist. Surgeon. Granted leave of absence for six months. S. O. 137, c. s., A. G. O.

KIMBALL, J. P., Assist. Surgeon. To accompany battalion of Twenty-second Infantry from Forts Brady

and Mackinac to Fort A. Lincoln, D. T., for duty under General Terry. S. O. 127, Military Division of the Atlantic, July 9, 1876.

King, J. H. T., Assist. Surgeon. Assigned to duty as Post Surgeon at Fort Concho, Texas. S. O. 121, Department of Texas, June 30, 1876.

Harvey, Phil. F., Assist. Surgeon. To accompany battalion of Twenty-second Infantry, under command of Lieut. Col. Otis, to Fort A. Lincoln, D. T., for duty under General Terry. S. O. 127, c. s., Military Division of the Atlantic.

Dickson, J. M., Assist. Surgeon. Granted leave of absence for one month from September 1st. S. O. 129, Department of the Gulf, July 8, 1876.

Tesson, L. S., Assist. Surgeon. To accompany battalion Fifth Infantry, under command of Col. Miles, to Department of Dakota. S. O. 139, Department of the Missouri, July 8, 1876.

Medical Items and News.

Contagious Diseases.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending July 15, 1876.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.
July 8.....	0	5	29	1	37	53	8
July 15.....	0	10	21	3	14	31	12

The following is a record of cases of contagious disease reported at this Bureau for the quarter ending June 30th, 1876:

Number of cases of typhus fever, 3; Typhoid fever, 89; Scarlet fever, 876; Cerebro-spinal meningitis, 39; Measles, 612; Diphtheria, 934; Small-pox, 285.

Practice of Medicine in France.—No medical man can practise in France without a license, which costs several hundred francs yearly; neither dare he write a medical certificate or similar legal document except on paper bearing the government stamp.

Sir William Fergusson's condition has undergone no material change within the last fortnight.

Cholera is now raging in Cashmere.

The Plague.—At Bagdad the daily average of cases is eighty and that of deaths sixty.

The meetings of Medical Societies in New York have adjourned until September.

The death of the Sultan is now admitted to be the result of suicide committed in a moment of desperation by opening the arteries of both arms by a pair of scissors.

British Medical Service.—Owing to the growing deficiency of medical officers in the British Army, it is stated that leave of absence in several of the home districts has been peremptorily stopped, and that at Woolwich every medical officer has extra duties imposed upon him. So much for the new army warrant.

Examination by Proxy.—A medical student, named Dearden, has been lately apprehended on the charge of defrauding the Board of Examiners of Glasgow University, by employing another man to represent him at the preliminary examination.

Annual Report of the Marshall Infirmary, Troy.—The following is a summary of the operations of the hospital for the year ending August 2d, 1875: Total number of patients remaining under treatment at the close of the year was 45—males, 30; females, 15. The number of patients admitted during the year was 235—males, 168; females, 67. Total number of patients under treatment during the year was 280—males, 198; females, 82. Of this number there were cured 146—males, 109; females, 37: improved, 40; males, 29; females, 11: unimproved, 19—males, 9; females, 10: dead, 19—males, 12; females, 7. Total number discharged during the year was 231—males, 163; females, 68. The number of patients remaining under treatment at the close of the year was 49—males, 35; females, 14.

In Commemoration of Traube.—At a late meeting of the Berlin Medical Society it was decided to hold a special meeting to do honor to the memory of Traube.

Death of Prof. Richter.—On the 24th of May, Prof. Hermann Eberhard Richter, known wherever medicine is read in the German language as editor of *Schmidt's Jahrbücher*, died in Dresden, at the age of sixty-eight. Widely and well known as he was in this position, he was also most favorably known in Germany as founder and editor of the organ of the German Medical Union. His efforts to promote union among physicians and to advance their standing were unwearied, and the profession in Germany feels largely indebted to him for procuring governmental recognition and appreciation of the medical associations. He also took great interest in sanitary science and the development of sanitary legislation. He published several works on various medical topics.

Five Children at a Birth.—The *Melbourne Medical Record* reports the case of the wife of a native who at one birth created a family of five children, three sons and two daughters.

Dissection is now legalized in Australia.

Midwifery Engagements.—In England a medical man can claim by law an obstetric fee if previously engaged to attend a case, even if the birth takes place in his absence.

Female Doctors.—Within the last ten years the University of Zurich has conferred the diploma of Doctor of Medicine on thirteen ladies.

Vivisection in England.—The Council of the Royal College of Surgeons of England has expressed the opinion that legislation on the vivisection question is unnecessary and subversive of the interests of science.

The *New York Medical Register* for the ensuing year (Dr. A. E. M. Purdy, editor) is published, and presents, typographically speaking, an elegant appearance. It contains the names of 3,805 physicians, divided as follows: in New York City and county, 1,190; Brooklyn and Kings county, 380; the remainder of New York State, alphabetically arranged, 1,267; in New Jersey, 589; and in Connecticut, 379. The number of removals in this city during the past year have been 168; new names added, 89. The removals in Brooklyn were 70, and the new names 26. As a whole, the work fully sustains its well-earned reputation for completeness and accuracy.

British Medical Association.—The next annual meeting of this Association will be held at Sheffield, commencing August 1.

Original Communications.

THE RELATION OF LOCOMOTOR ATAXIA TO GENERAL PARALYSIS OF THE INSANE.*

By ALLAN McLANE HAMILTON, M.D.,

VISITING PHYSICIAN TO THE EPILEPTIC AND PARALYTIC HOSPITAL, NEW YORK, ETC.

I DESIRE to invite attention to the subject of sclerosis of the posterior columns of the cord, and its coexistence more particularly with that form of insanity known as general paralysis of the insane. Not only do these two conditions occur together more frequently than they are generally supposed to, but the former very often presents the most varied mental expressions, passing from simply irritability to marked dementia.

Leidesdorf† has related one case in which general paralysis was preceded by spinal symptoms, and Maudsley speaks of other cases. Calmiel says that in many cases the changes proceed from the cord upwards, and Baillarger endorses the views of the last-mentioned authority. From a consideration of the fact that sclerosis is nearly always progressive, and that locomotor ataxia is in many instances ascending, it is very probable that either an extension upwards of the morbid process, in such a way as not to involve the roots of the intercostal nerves, or, on the other hand, a simultaneous and general appearance of disseminated sclerosis in the cerebrum and cord, will very probably be attended by mental disturbance. In most of the autopsies that have been made, decided changes have been witnessed in the layers of the cortex; we may therefore assume that a lesion in the gray cortical matter may be attended by intellectual perversion. Charcot has proved very conclusively, by the classical case of Mlle. V., that disseminated sclerosis can exhibit all the symptoms of general paralysis of the insane; that intellectual trouble, even including the delusions of wealth, or, as Valentenir calls them, the *délire des grandeurs*, may occur in patients of this class‡

We find also that in these people there is often a great deal of emotional disturbance. Every one who has seen much of locomotor ataxia will recognize the melancholic attacks, or the great excitability. I have a patient in whom the spinal sclerosis has extended so high as to greatly affect the origin of the intercostal nerves; and in her, transitory attacks of mania are not at all uncommon. She becomes violent, hurls abuse at those around her, and talks only in French; her chosen language at ordinary times being the English. Charcot relates that Mlle. V. was subject to true attacks of lypomania, and had hallucinations of hearing and vision. She had delusions that those about her intended her death by poison. For twenty days she refused food, and it was found necessary to use the feeding tube.

With these things in mind, it is very reasonable to conclude that general paralysis is but the expression of disordered function produced by the same lesion that causes decided pelvic trouble and locomotory perversion, when it is seated in the cord. The form of morbid alteration of the brain and its meninges, I think, has very little to do with the formation of any particular variety of insanity; that it is a matter of location rather than of alteration. In any of the lists of morbid appearances we will find all forms of altered structure,—meninges, gray and white substance,—are involved, and we do not find any two forms of insanity which present identical appearances. If you will consult Fox, which is the most complete work I know of, you will see that there is a great deal of confusion and irregularity of information that may be obtained from the examination of the insane brain.

Perhaps the morbid anatomy of general paralysis of the insane is more clearly settled than all the rest. Delaye, Foville, and Pinel (Grand-Champs) found induration of the cerebral substance; Fox presents a plate illustrating the miliary sclerosis of general paralytics, and I myself have seen the same changes on isolated spots, varying in size from a small speck to the larger spots of colloid degeneration. That these appearances are the result of primary ischæmic trouble there is not much doubt. Fox is of the opinion that a prolonged spasm of the vessels, and subsequent condition of degeneration, are the precursors of actual increase of the connective tissue. In the cord, clinical experience teaches us that conditions of altered vascularity precede sclerosis in every instance, and that marked functional changes are the forerunners of locomotor ataxia. In the brain the primary alteration of function, however slight, may be connected with decided interference with the intellectual processes, and sometimes when these patients die before the disease has extended, it will be exceedingly difficult to detect any alterations, either gross or microscopical, while in the cord, if ataxic symptoms have developed themselves, in nine tenths of the cases there will be seen unmistakable traces of induration.

Notwithstanding so many observers consider the lesions in general paralysis to be those of sclerosis, Calmiel, Poincaire, and Bonnet thought that they were more often softening, and fatty degeneration; in fact, others take equally opposite views, but the great majority hold to the other doctrine. With the anatomico-pathological facts in mind, it is strange that the true conditions are not more frequently seen together. In my own limited experience I have seen several cases which presented an extension of the symptoms.

Obersteiner,* in an excellent paper upon Locomotor Ataxia and Mental Disease, considers that mental symptoms are found in the greater proportion of cases of this disease, and calls attention to the fact that these expressions of psychical trouble may be very slight, but still an acute observer will know that there is a departure from the normal intellectual condition. The patient's character is often changed very markedly. I have been often astonished at the apathy of the individual, or, on the other hand, the irritability of temper, the violence of anger, the petulance, which are more than transitory evidences—they are as important symptoms, I think, as neuralgic pains, difficulty of coördination etc. These changes were very well displayed in a patient of my own: in health a most amiable, high-minded army officer; in disease a morbid, bad-tempered, whining wreck. He had been noted for his gallantry on the field during the war; but after this disease had become once established, his character seemed to undergo a complete transformation. He wrangled with every one; became irritable over petty things, and made himself generally disagreeable.

Obersteiner† and Simon‡ both agree that these

† Loc. cit.

‡ Archiv für Psychiatrie, I. & II., 1875.

patients should be examined most carefully, and that the prognosis depends much upon the facts relative to mental alterations. The latter says: "It is not enough that the patient keeps himself quiet, and answers the questions relative to his age, how he feels, etc., and does not show marked delusions;" these are not enough to assure us that his intellect is intact.

In regard to the grave secondary mental changes, Tigges* considers general paralysis to be a complication, while Oberstiener is convinced the symptoms of this latter disease indicate a progression of the sclerosis upwards. He considers the lesions to be identical, and that it is only the seat of the change which has anything to do with the form of symptom expressed. He has also found in general paralytics who have died, a sclerosis of the cords.

The commencement of paralysis of the insane is not regular. We may either have the mental symptoms preceding the paralytic, or *vice versa*, or they may both show themselves simultaneously after a form of apoplectic attack.

M. Rey, whom I have alluded to, has observed nine cases of insanity associated with locomotor ataxia. In three of these the spinal sclerosis preceded the cerebral trouble, and in one the induration had extended from the posterior to the lateral columns. He found that the diagnostic difference between locomotor ataxia combined with cerebral induration and simple descending general paralysis of the insane, was the walk. In the former the patient could not stand with his eyes shut, and in the latter there was no difficulty of the kind. We may also take for granted that the walk of the ataxic is an early sympton, and that of the general paralytic a late one. Both are examples of defective coördination, and I think the latter is very unwisely called *paralytic*. I have found in these patients (the general paralytics) *festination*, which Sanford considers to be confined to paralysis agitans, and is an evidence more of sclerosis than anything else.

The difficulty of turning around is marked in ataxis, and I think is not a prominent symptom in general paralysis.

Though Sankey has presented us with a table showing the points of difference of the two diseases, I think it wise to give one that is more extended. Some of these symptoms will be found to very closely resemble each other, and I am assured will show how possible it is for the two diseases to run into each other.

GENERAL PARALYSIS.	LOCOMOTOR ATAXIA.
Initial Mental Symptoms.	
Slight irritability of temper. Extravagance (the patient purchases unnecessary articles, or spends money without reference to his means).	No mental trouble, except perhaps irritability.
Erotic and libidinous idēas and indulgences.	At first diminished sexual power, afterwards an increase.
Initial Material Symptoms.	
Slight impairment of muscles about mouth, and tremor of tongue (when protruded it is agitated by vermicular tremors).	No affection of tongue, nor of any muscles of face, except those supplied by third nerve.
Pupils unequal.	Pupils generally contracted, sometimes dilated after an attack of pain. Strabismus a frequent symptom.
Patient unable to properly pronounce his words; his speech is thick and very slow (Ronquin); stammering (Griesinger).	No disturbance of speech.
Patient begins to lose power in both upper and lower extremities; he does not raise his feet; walk somewhat straggling; feet planted rather widely apart. Patient inclined to walk a great deal.	Gait jerky; patient comes down on heels, feet thrown out with force. Patient unable to walk in dark.
Patient can stand with eyes closed.	Patient cannot stand with eyes closed.
Difficulty of coördination of upper extremities generally primary.	Difficulty of coördination of muscles of upper extremities always secondary.
Patient cannot perform delicate muscular acts, particularly writing. He leaves off the ends of words or omits the word altogether—(early stages).	Patient cannot perform delicate acts with muscles of upper extremities—(late stages).
Patient boastful, irritable; has delusion of great wealth; violent; will not bear contradiction.	Patient may have moral perversion; in last stages there may be mania. Attacks of melancholia not uncommon during progress of the disease.
Occasionally local paralysis, generally on one side.	Never paralysis.
Tremors in limbs.	Tremors only occasional.
General loss of electro-muscular contractility in late stages (Bucknil).	Exaggerated electro-muscular contractility in the beginning, loss later on.
Very slight muscular atrophy (Marcé, Brierre de Boismont).	Very slight atrophy of muscles of lower extremities, more from disuse than anything else.
Diminution of reflex excitability.	Diminution of reflex excitability; loss of muscular sense.
The progress of the disease in general is from above downward (Calmiel).	Progress from below upward.
Disturbances of sensation are sometimes primary. There is sometimes hyperæsthesia.	Disturbance of sensation are always primary; generally cutaneous anæsthesia at some time.
Generally runs its course in a few years.	Of much longer duration.
There may be periods of remission.	Disease progressive.
No marked involvement of bladder or rectum till the end.	Generally obstinate constipation; sometimes paralysis of both sphincters.
Usually terminates in dementia.	No mental decay as a rule. Patient dies of phthisis.
During the progress of the disease there may be paralysis of various cranial nerves.	Not uncommonly the fifth, sixth, third, and optic nerves may be affected.

From an inspection of this table, it will be evident that there is a close similarity between the symptoms of the two diseases, which I think may be explained by the difference of location. In both defective coördination is marked. In both reflex action is lost. In both there may be tremor. In one the disease is an evidence of lesions in the cortex, in the other in the white or gray matter of the cord. Both may be seen in the same individual, and after death the lesions

* Allgemeine Zeitschrift für Psychiatrie, 1871.

are the same. The mental symptoms may be identical, although always differing in the period of appearance. Ocular difficulties may be present in either, as may difficulties in speech. Both are progressive and generally fatal.

It now remains for me to relate a case which lately came under my charge where the sclerosis of the cord was ascending, and in an incredibly short space of time the cerebral symptoms which indicate the general paralysis of the insane were evident.

M. F., aged twenty-nine, United States. On admission to the Epileptic and Paralytic Hospital, March 6, 1876, I was immediately struck by the woman's walk, which was ataxic in the extreme, and on questioning her and her husband we ascertained that about two years ago she had neuralgic pains in the legs and feet; her walking became defective, and has continued so. Her mind has been clear up to a short time ago. Her pupils are now unequally dilated, the left being the largest. Her lips quiver distinctly, and her tongue, when protruded, also quivers. When told to keep it quiet the motion is greatly exaggerated. There is some ptosis of the left eye. When told to close her eyes she is unable to coördinate delicate muscular movements. She cannot find the tip of her nose with her forefinger by more than an inch. When her eyes are open she cannot touch small points, such as the markings upon my watch-dial. When she stands with her eyes closed she topples over almost instantly. When she walks her toes are thrown out, and she comes down upon her heel. Her feet are planted far apart when she attempts to stand. When walking across the room she reels, and has difficulty in turning around. When attempting to answer questions she talks slowly, each word being uttered with some effort; the words containing the letters "f" and "p" are *explosive*, and the lips seem to have a great deal of work to form them. The consonants are slurred over; for instance, the word "man" is pronounced "mah," the "l's" are dropped, as are many other letters. Her writing is very scratchy and irregular, although her husband says she wrote an excellent hand. Mentally she is silly, and laughs immoderately at wrong times and without cause. She has no idea of time, but seems to know what she is saying. She has had several delusions, one of which was that she had been home the day before.

May 12th; two months after admission.—Her walk is much worse; no urinary or other difficulty. There is some festination; pupils still uneven. The difficulty in speech has markedly increased. Her tottering walk is very striking. We at first thought she had syphilis, but this is not so. Being unmanageable and restless, she was transferred. Here undoubtedly was an ascending condition, beginning with the pains and gait of locomotor ataxia, and ending with several early symptoms of general paralysis.

A case related by Obersteiner* illustrates another phase of this connection of symptoms of both diseases in one patient. There was undoubtedly a predisposition to mental trouble. It is to be regretted that a *post-mortem* examination was not made, for the case was a most interesting one.

M. D., banker, Vienna, æt. 49. Entered hospital May 1, 1869. Patient was always well, and, although uneducated, was a clever mathematician. Married twenty years; has five children; in good circumstances. Noticed, without any known cause, at the end of the year 1865, an increasing weakness of lower extremities, and loss of sensation therein. Soon after that darting pains were felt, which were not relieved by medicine, and increased in the fall of 1868 to the involvement of the entire legs, and the pains occurred particularly at night, with incontinence of urine. At the same time there was decrease of mental power. In December of same year, suddenly a severe apoplectic attack occurred, after which he became insane and was very violent. The restlessness and mental weakness kept on until he was admitted into the institution, when he exhibited a loss of all shame. Exalted ideas were well marked. He bought the whole house, and had control over millions to furnish this mansion in a beautiful manner. He was very violent. Speech became thicker and more unintelligible. He grew mentally and physically weaker, and in October, 1869, was taken home to receive private nursing, and died there in the year 1870. This patient presented a very good example of tabes, which after three years' duration attacked the brain, while before the psychical functions were not perfectly performed. This whole process showed itself as ascending dementia paralytica.

M. Hayem* described before the Society of Biology a case which presented remarkable cranial symptoms, and I will briefly outline the case, as I consider it to be one illustrating my subject.

H., aged thirty-seven years, entered La Charité Nov. 23, 1874. Parents both healthy. The patient is of feeble organization, and at the age of eight years he had scarlatina, but has never had any other serious trouble. He was a clerk, and wrote a great deal previous to admission. Toward the end of 1861 he felt "hot and cold," and on the cold days he had pains in his limbs which were darting. Toward the end of October (a month before entering the hospital) there was strabismus, with especial trouble in the right eye; there was marked diplopia. These symptoms were experienced only when the effort to write was made. He subsequently found difficulty in holding the pen. The muscular troubles in his fingers were even preceded by feelings of formication. The mind was unaffected.

Condition of Patient, Dec. 1.—The appearance of the patient indicated that he had suffered great privation. He is thin, pale, very anæmic. The painful points on the side of the nose are detected; there is considerable muscular atrophy of the face; many of the teeth have dropped out since the beginning of the trouble, and those that remain are carious. The muscles of expression are not paralyzed. The right pupil dilated more than the left, and the sight is more feeble in the right eye. In the right side of the face there is some loss of sensibility. Sense of smell intact.

The arms and hands are considerably atrophied; the sensibility is lowest in the skin of the right hand; no points of analgesia; sensibility to temperature is unaffected. When the eyes are closed the movements of the superior extremities are uncertain, particularly the right arm. Delicate acts of coördination are impossible. The sensibility of the shins, thighs, legs, and feet is increased. He is unable to stand with his eyes closed, and does not know when legs are changed which is which. His walk is uncertain; the right leg is more feeble. He does not feel as if he is walking on elastic balls. No headache, nor sleeplessness.

Dec. 22.—Progress of disease is slow.

Jan. 2.—Coördination more difficult.

Feb. 3.—Patient unable to leave his bed; can hardly walk. Lung trouble recognized. Both his eyes are directed to the sun, and he does not mind the light.

Feb. 4.—Painful sensation in the neck and right

* Wien. Med. Woch., No. 29, 1875.

* Gaz. Méd. de Paris, 1876, No. 19, p. 219.

eye; vision very feeble. The muscles of shoulders are atrophied.

Feb. 8.—Reflex movements can be still produced; the limbs are losing power gradually. No headache nor noises in the ears. Lung trouble increased.

Feb. 12.—The feebleness increased; "*il y a une véritable atrophie du système musculaire.*" Patient during the last few days has had difficulty of speech; speaks very slowly; the voice is somewhat nasal. No paralysis of the veil of the palate.

Feb. 25.—Constipation for several days.

March 5.—Feebleness and emaciation extreme. Bedsores. Incontinence of urine. Speech embarrassed. Diarrhœa.

March 7.—Pain in the throat. Sensibility completely disappeared in limbs. Fever; delirum; pulse 120°. Almost complete loss of reflex sensation. Œdema of left leg.

March 12.—Complete paralysis of legs. Tongue dry; speech almost abolished. All muscles contract to electric stimulation.

Autopsy.—The lungs were emphysematous. Exudation in pleura, etc. Kidney large and congested. Heart small; disease of mitral valves. *Head:* Dura mater healthy. *Brain and Cord:* Induration and atrophy were found at cervical lumbar regions. The posterior and right lateral columns are more altered than the opposite side. Vessels of brain healthy. The optic nerves were healthy except in the centre, where there was a gray deposit. The motor oculi were the seat of the same lesion at their apparent origin. The meninges were very vascular. There was no cortical trouble. The other parts of brain were apparently unaffected

Microscopical examination showed sclerosis of the post. column of the cord, with great quantity of granular bodies. The central canal was obliterated in the dorsal region; there is also sclerosis of the lateral columns.

The alterations in the medulla were seen at the root of the trigemini. The pyramids were healthy. Points of sclerosis were found at the nucleus of the facial, and in other parts. The motor oculi nerve were found greatly degenerated; a hyperplastic condition between fasciculi and a reduction in size of the nerve-tubes.

In the next case, one of my own patients, the symptoms of sclerosis were preceded for some years by epileptic attacks. I am inclined to think that the lesion existed in the white matter, and was gradually followed by changes in the gray substance both of the cord and brain. Her symptoms are very marked, both mental and physical, and are characteristic of abnormal changes of slow growth.

J. W., forty seven years, married. Condition on admission.—Has sharp pains in the legs, which first came two years ago; she calls them "striking pains." Tactile sensibility fair, and she appreciates touching and pinching. Reflex movements fair. Muscles of calf well nourished; some loss of coördinating power; cannot put the heel of one of her feet on the toe of opposite foot. Fingers numb. Marked ataxia of upper extremities; no diplopia, nor other weakness of vision. Very much constipated; menstruation irregular. She has had epileptiform attacks for the last twelve years, which occur at night. With the present symptoms there is considerable tremor in the upper extremities, which is increased with voluntary movements. Her hands are now numb and heavy. Her body sways to right and left when she walks. *Mental condition:*—Memory greatly impaired. Every two or three weeks she indulges in delusions of the most extravagant character; is emotional and tearful. She very often uses the French language, talking with a great deal of rapidity, and without a thought of what she is saying. She is easily excited, at other times she passes many hours of the day reading her prayer book. This is her present condition, and her disease has progressed but very little in the past year, except that her mind is more affected and her upper extremities are more involved. Her lips now tremble and her speech is somewhat thick. She cannot stand with eyes closed when unsupported. There is a slight history of syphilis, which is very uncertain. She lately had very extravagant delusions in regard to her home and her husband's condition. Has great difficulty in turning around. Her lucid intervals are very short.

In conclusion, I must refer to the fact that sclerosis in either of its forms is not unrarely preceded or associated with other nervous diseases. Mollière calls attention to Charcot's discovery that hysteria often preceded locomotor ataxia. Magnau has detailed cases of epilepsy connected with locomotor ataxia, and as for the complications of general paralysis, several English writers, chief of whom, if I am right, is Clouston, speak of chorea, epilepsy, neuralgia, and other neuroses as being very common.

PERINEAL LACERATION TREATED BY IMMEDIATE OPERATION.

By EDWARD J. BERMINGHAM, M.D.,

NEW YORK.

F. R., a delicately framed but healthy country girl, æt. twenty, primipara, was delivered of a living child instrumentally on the morning of the 30th June, 1876, upon which occasion I was assisted by Dr. J. J. Henna. Although every precaution was exercised to prevent such an accident, the perineum was lacerated to a considerable degree—the rent extending through the sphincter ani, and up the recto-vaginal septum about 1¼ inches. After a brief consultation, we decided to operate immediately, and accordingly, before the patient had recovered from the effects of the chloroform which had been administered prior to the application of the forceps, the ruptured surfaces were brought together in the usual manner, by interrupted silver sutures deeply introduced.

℥ ij. of Squibb's fluid extract of ergot was now administered to keep the uterus firmly contracted, and the knees were bandaged together. A couple of hours later this bandage was removed and the patient was placed in Sims' position, to prevent the lochia from flowing over the wounded surfaces. This position was maintained as much as was tolerable for the patient, and when she was permitted to rest on the back the thighs were not bandaged but allowed to remain apart. The urine was drawn off periodically by means of the catheter, and morphia was administered in sufficient quantities to relieve pain and confine the bowels. The vagina was periodically syringed with carbolized water, and the parts both externally and internally were kept scrupulously clean.

No bad symptoms supervened; the sutures were removed on the sixth day, when union was found to be complete. From this out the bowels were moved by laxatives, and on the 12th of July the patient was sitting up and feeling perfectly well. A thorough examination of the parts at this time showed their complete restoration to the normal condition.

The result of the operation in this case exceeded

our most sanguine expectations. As a rule, immediate operative interference in cases of rupture of the perineum does not seem to be warrantable. If the laceration; be incomplete it oftentimes heals by first intention, and surgical measures adopted for extensive complete rupture extending up the septum, as in this case, but too often give a bad result.

The reason of this non-success in many cases I believe to be due to the carelessness or incompetency of the nurses having the subsequent care of the patients. It is therefore of the utmost importance that the practitioner should attend to all the minutiæ himself. Another measure that should be considered as absolutely necessary to the success of immediate operation is the maintaining of the patient in Sims' position.

This will probably meet with a very decided opposition, but it is the duty of the attendant to insist upon it for a few days, as the only hope of a happy recovery. By this procedure the wounded surfaces are freed from the irritant lochia, and the battle is thereby more than half won.

102 West Forty-ninth Street.

Reports of Hospitals.

BELLEVUE HOSPITAL.

Notes of Practice and Peculiarities of Treatment.

AN ASYMETRICAL DEFORMITY.

There was a peculiarity in the case of deformity before us which is only occasionally seen, namely, lack of symmetry depending upon paralysis of the perineal muscles on the left leg and the tibialis anticus on the right.

FRACTURE OF THE EXTERNAL CONDLYE OF THE HUMERUS—NEGLECT OF AN IMPORTANT ITEM IN THE CASE.

A stout, healthy boy, aged seventeen, received a blow which gave rise to fracture of the external condyle of the right humerus. The limb was dressed in the fully flexed position, and passive motion commenced as early as possible. The manipulations were steadily kept up, and each day a perceptible gain was made until good motion was secured at the elbow-joint, such as enabled him to extend the forearm fully and to touch the shoulder with the hand. Strict injunction was given that the passive motion should be continued daily for a long time; but the boy went out, engaged in business which called into action the hands and wrists chiefly, and entirely neglected to attend to the motions of the elbow-joint. The result was, that he returned to the hospital after a short time with the forearm flexed at nearly a right angle with the arm, and the elbow-joint almost in a condition of false anchylosis.

REMARKABLE DURATION OF JAUNDICE—A POINT OF PRACTICAL VALUE IN CERTAIN CASES.

In the case before us jaundice was the only symptom. It was very marked, and had been tolerated without special inconvenience for nearly four years.

INSIDIOUS APPEARANCE OF PLEURISY WITH EFFUSION—PATIENT UNDER TREATMENT FOR HÆMATURIA.

A male patient entered the hospital and submitted to treatment for the relief of hæmaturia depending upon some cause not well understood. After he had been in a short time he complained of a very trifling cough, without expectoration, without fever, without marked shortness of breath, and upon examination of the chest evidences were found indicating the presence of fluid in one pleural cavity, as high as the spine of the scapula. No marked inconvenience was experienced by the patient, and that fact, together with the insidious approach, made the case worthy of note.

PLEURISY WITH EFFUSION IN A NURSING WOMAN—IMPORTANT QUESTION RELATING TO TREATMENT.

The rational symptoms and physical signs made the diagnosis of pleurisy with effusion, in the case before us, positively correct. The patient had a babe one month old, and the question arose, should the woman continue to nurse her child? Notwithstanding the weakened condition of the mother it was believed to be better that she should continue nursing, for the reason that the secretion of milk actually assisted in the removal of the fluid effused into the pleural cavity. Allow the child to nurse and compensate for the extra draught upon the nourishment of the mother by furnishing an extra amount of nutritious food. Besides, it was thought best not to wean so young a child just before the beginning of the hot season, unless circumstances rendered it absolutely necessary.

A NOTABLE CASE FOR HISTO PATHOLOGICAL INQUIRY.

A male patient had suffered from acute articular rheumatism, double pleurisy, pericarditis and bed-sores, and bade fair to elude the grasp of the pathologist by getting well.

EXCEPTIONAL SITUATION OF A POPLITEAL ANEURISM.

A laboring man, æt. 42 years, in whom no history of syphilis could be obtained, and whose habits were moderately good, was engaged, four months ago, in dragging three bags of oil-cake, weighing three hundred pounds, up an inclined plane, when he experienced a sensation in the left leg, just below the knee, as though some one had struck him a blow. So certain was he that he had been struck, that he inquired as to which one of his companions had given him the blow. He suffered some pain immediately after the occurrence of the accident, but did not discontinue his work, and was not much annoyed with symptoms for a period of two months. During that period, however, when straining at work, and sometimes when quiet in bed, he experienced an itchy sensation, and occasionally a pain, in the lower part of the popliteal region of the left side. Two months after the occurrence of the accident, he first noticed a tumor in the same region, but it was not large. To obtain relief a variety of external applications were made; but at the end of the third month after the accident he was compelled to abandon work. The tumor at the time of the operation, four months after the occurrence of the accident, had increased the circumference of the limb two and a half inches, and the entire limb below its situation was somewhat swollen. The situation of the tumor was quite exceptional, for it was found to overlap only a small part of the outer and lower border of the popliteal space; the chief extent being to the outer aspect of the leg and below the popliteal space. The question arose: was not the tumor a pulsating tumor of the bone? It was believed to be an aneurism, because it was a pulsating tumor,—a tumor with thin walls, a tumor that could be reduced in size by pressure upon the tumor itself, and also upon the artery above it, and was a tumor over which a distinct murmur could be heard, synchronous with

the first sound of the heart. For its cure the femoral artery was ligated, and the patient did well.

EIGHT ATTACKS OF ARTICULAR RHEUMATISM BETWEEN THE AGES OF FOUR AND TWELVE YEARS—ABSENCE OF CARDIAC COMPLICATION.

The first attack occurred when the boy was four years old; the last during the past winter, and extended over a period of six weeks before he was able to walk without the aid of crutches. The first attack involved the ankles and knees, confined him to the bed and house, and lasted about three weeks; the intervening attacks had varied somewhat in severity and duration, but had usually continued three or four weeks. Upon physical examination of the chest no evidence of cardiac complication could be found. Why the boy should have escaped heart disease after having had eight attacks of articular rheumatism between the ages of four and twelve was a question. It was possibly due to the mildness of the attacks.

CONGENITAL MITRAL STENOSIS.

The girl had not suffered any inconvenience from the cardiac lesion until puberty had arrived, when she began to experience "uneasy sensations," some pain and palpitation in the præcordial region. The murmur indicative of the lesion mentioned could be heard with the greatest ease. To improve the general nutrition of the patient was the idea involved in the treatment. For that purpose Vallet's mass was prescribed in four-grain doses, three times a day, and at the end of a week there was marked improvement. Rest was enjoined and also a nourishing diet Cod liver oil was not recommended because of a probable inability to digest it properly. Iron was believed to increase nutrition in some way, besides its mere effect upon the blood.

THE INNOCUOUSNESS OF VALVULAR MURMURS OF THE HEART, ILLUSTRATED BY CASES.

A male patient, æt. 27, was admitted to the hospital Nov. 5, 1875, and stated that, ten years ago, having fallen from a scaffolding, he immediately experienced great dyspnœa, expectorated blood, and some blood came from his ears. For some time after receiving this injury he suffered from cardiac palpitation and severe dyspnœa upon exertion. The patient was temperate, but admitted that he had venereal disease. He had never had rheumatism, but distinct evidence of aortic lesion was present. That fact led to the remark that aortic lesion in a patient who was not advanced in years, and who had never had articular rheumatism, was strongly suspicious of syphilis. For many years he had suffered but little from his cardiac trouble. It was thought quite propable that the heart sustained an injury at the time the patient received his fall.

AORTIC DIRICT AND REGURGITANT MURMURS.

In this case the murmurs were sufficiently distinct to be easily recognized, but the inefficiency of the valves was probably not extensive for the reason that there was only moderate cardiac enlargement. The man had never had general dropsy, or cough, or expectoration. He had complained of dyspnœa, but upon close examination it was evident that he did not draw a very nice line of distinction between dyspnœa and palpitation. The clinical teacher remarked that he should say to such a patient, "Your heart is unsound, but that does not involve any immediate danger or immediate serious consequences, and is not inconsistent with a fair degree of health." The great aim in the treatment was to control accessory circumstances, such as those relating to exercise, habits, diet, and the general nutrition of the patient.

TOLERANCE OF CARDIAC LESIONS—MARKED MITRAL DIRECT AND SOFT REGURGITANT MURMURS—DOUBLE AORTIC MURMURS.

These murmurs occurred in a male patient, æt. 30, who denied venereal, but was accustomed to the use of alcoholics, and had his first attack of acute articular rheumatism five years ago. From time to time he had had slight hæmoptysis. Two years ago he first noticed palpitation upon exertion, and occasional attacks of dyspnœa, which had modified somewhat in severity. The attacks of dyspnœa had increased in frequency during the last eight months. It was quite probable, however, that in this case also very much of what the patient recognized as dyspnœa was nothing more than cardiac palpitation. There was but little enlargement of the heart. The case, therefore, showed the tolerance of cardiac lesions. In this connection the question arose: can we have pulmonary hemorrhage dependent upon mitral obstruction, before the heart becomes enlarged? It was believed to be possible, but it was regarded as rare for profuse bronchorrhagia to occur dependent upon that lesion.

MITRAL REGURGITANT MURMUR.

This murmur was found in a male patient, æt. 23, who had been intemperate, had had syphilis, and four years ago had had acute articular rheumatism. The cardiac impulse was slightly strong, which was the only present evidence of cardiac hypertrophy. The patient suffered from headache, præcordial pain, dyspnœa, dizziness, and palpitation, all of which were increasd upon exertion. At the same time there was a murmur, with the first sound at the base of the heart, and it was suggested that that fact would explain many of the symptoms from which the patient suffered. The prognosis was by no means unfavorable, as regarded serious consequences within a short period of time. It was remarked that a slight amount of regurgitation might be tolerated for an indefinite period. The existence and character of cardiac lesions, however, should be determined in each and every case.

REMARKABLE LIMITATION OF THE SYMPTOMS OF CHRONIC GASTRITIS TO THE STOMACH.

The man had been sick four years. The first thing that attracted his attention was vomiting, and for two years an attack came on every fourth week, lasted from three to five days, and then ceased. Then came five months of cessation from vomiting. During the succeeding two years the vomiting occurred every third week to the very day, generally taking place before breakfast, and continued throughout the attack with only an occasional hour's interval. The vomiting was not accompanied by pain, but the day previous to its recurrence the patient was able to say that an attack was approaching, on account of a feeling of uneasiness and discomfort in the abdomen. Latterly the man had only a feeling of nausea, with regurgitation of a slight amount of fluid into the mouth during the morning. The material which he had ordinarily vomited had been simply a yellowish, frothy, sometimes bitter, sometimes watery substance. He had lost flesh and strength; had no appetite for his morning meal; but towards night was able to eat quite well. His bowels were regular, and had been undisturbed throughout his entire sickness. The symptoms had been limited to the stomach. There had been no headache or vomiting of blood.

It was believed that the case would receive the most certain and the most permanent benefit from the use of the stomach pump. It was recommended to wash out the patient's stomach with tepid water from two to four times a week, and continue that plan of treatment for some time. Patients very readily learned to do it themselves, it was said, and as the general condition improved, the pump could be used less and less frequently, and recovery would probably be complete. If for any reason that plan could not be carried out, it was recommended that powders containing bismuth and cubebs, five grains each, should be administered three times a day. It was also advised that a trial be made to ascertain whether acids or alkalies agreed best with the condition of the stomach. It was thought probable, however, that the good effect of the powders of bismuth and cubebs could be increased by combining with them five grains of the bicarbonate of soda, but at the same time it was a fact worthy of note that some patients were made worse by alkalies, while others were decidedly disturbed by the use of acids. The patient had been accustomed to the use of the sour wines, and, perhaps, the setting aside of those and substituting an alkali would be beneficial. The Rhein wine was regarded as a very good acid preparation to recommend in cases where acids were required. The digestion of a great many old people might be materially improved by the use of an acid while taking their dinner, and the Rhein wines fulfilled such an indication very well.

Progress of Medical Science.

A Case of Ureteroplasty.—By Prof. Nussbaum, of Munich. (Abstract from Bavarian *Intelligenz Blatt*, by Dr. Petershausen.)—Ovariotomy had been performed more than a thousand times, when it happened that Prof. Simon, of Heidelberg, accidentally cut through the left ureter at an operation. As he was compelled at the same time to remove a large part of the uterus, the urine afterwards ran both through the abdominal fistula, which formed itself in the cicatrix, and through the cervical cavity and the vagina. Great suffering was caused to the patient by this state of things. But at last the Professor ended her miserable condition by resorting to renotomy, which operation was a complete success, the remaining kidney soon assuming a two-fold function. Afterwards a similar misfortune occurred to Prof. Nussbaum, while removing an ovarian cyst of fifteen years' standing. The most difficult part of the work was the separation of the tumor from the uterus. Thus far the operation was successful; but it was noticed that, after several days, the quantity of urine was much less than it should have been, while at the same time a watery excretion oozed out of the abdominal wound. A close examination of the excretion showed that it contained urine. As the bladder was not injured, it seemed that the injury resembled that in Simon's case. An examination proved that the right ureter, which was closely connected with the ovary, had been cut during the operation. The woman made a quick recovery, but as there remained an abdominal fistula, through which one-half of the urine escaped, the poor woman was so exceedingly troubled by it that the doctor at last concluded to put an end to her suffering. There were different methods which the doctor had in view for this purpose. In this case he thought it would be best to conduct the urine, excreted by the fistula, to the bladder by the shortest way. This could be done, either by uniting the cut parts of the ureter, or by forming an artificial one. The doctor intended to try the first method. The abdominal fistula was dilated for two days, by laminaria bougies. Then introducing his left forefinger into the fistula, he could reach a reservoir of the urine, and the termination of that part of the ureter which was connected with the kidney. To reach the other end of the ureter, the doctor widened the urethra by Simon's dilator, but he was unsuccessful in finding the termination of the ureter. When he introduced a male catheter into the bladder, and pushed the latter upwards by it, his left forefinger in the fistula could be touched, the intervening space being no greater than an inch. This space was now penetrated by a trocar, and in the opening there was introduced a drainage tube. To its lower part there was attached a glass tube with a broad margin, by which an escape of the drainage tube towards the fistula was to be prevented, while a silver wire, fastened to the upper end of the tube, was led from this point through the fistula, and, by strips of adhesive plaster, attached to the skin. The drainage tube, which in this manner was kept in position, was intended for a supplementary ureter. Incontinence followed for three days, but in general the patient got along nicely. Some days later the tube unfortunately escaped, in spite of its rim, through the newly-formed ureter, and this became obstructed by flocculent matter. The urine was again excreted by the fistula, and the doctor had to introduce another tube. The upper end of this was likewise connected with a silver wire, but it was so much longer that its lower end protruded from the urethra, so that the urine ran into a vessel. The patient was very unwell for some days; but little urine was excreted by the fistula. To the astonishment of the operator he found the drainage tube, two days after its introduction, upon the patient's belly. This tube had also slipped upwards, as in the previous instance. However, an injection of litmus solution convinced the doctor that the artificial way was still open, and consequently he did not introduce another tube. The artificial way kept intact, a normal quantity of urine was excreted, and when, several weeks later, a few drops of urine were still excreted by the fistula, which was then very narrow, this was closed by cauterization. The patient's health became excellent afterwards.

The Epidemic of Typhoid at Croydon, England.—Dr. Buchanan's report on the late epidemic at Croydon, appears almost simultaneously with the subsidence of the disease; having been at first epidemic, then endemic, typhoid fever has at last disappeared, after fifteen months' sojourn in the district. There have been in all about 1,200 cases of fever in 942 houses. The disease was due to "the escape of infected air from the sewers, and its inhalation by persons susceptible to the disease." The Croydon water, as obtained from the well, was perfectly pure, but the pipes which conveyed the water into the houses were very frequently the vehicles by which the sewer air found entrance into the infected houses. The sewers were insufficiently ventilated, and the flushing arrangements were so defective as to allow, and even compel, the contamination of the water-supply whenever the sewers were flushed; so that the more the essential means for the removal of the excreta from the sewers were put into practice, the more the water became polluted by sewer gas. This is surprising, because one of the by-laws of the local Board of Health requires that

there shall be no direct communication between the water-source and the sewers. In many of the best houses, overflow pipes were found going direct to the sewers from cisterns in confined situations under the bed-room floors, a position for cistern and protection from overflow that were positively contrary to the by-laws of the Board.

Dr. Buchanan shows conclusively that the fever bore no relation to the rain-fall. He points out that the fever was co-extensive with the Croydon water area; and that houses served with Croydon water contained cases of fever, even where the drainage arrangements were perfect. He quotes the case of a large school, in which the water supply, being from the same source, came on the boys' side direct from the main, and was often stinking, while there was no complaint from the girls' side, which was served after the boys' were provided for. The fever was on the boys' side alone. Some Condy's fluid was put into the main, and the greater part of it was drawn off from the boys' tap, scarcely a stain of it reaching the girls' side. The water was complained of as stinking in various parts of the water area, but when analysed it was found pure—the inference being that sewer gas had found admission to the water pipes and polluted the water; but with the escape of the gas all trace of pollution was gone.

The report concludes with the following recommendations:

1. All public sewers that are not in good order and equal to their work must be replaced by perfect sewers.
2. The by-laws must be carried out, and the sewers be completely ventilated in such a way as to secure a constant current of air through every foot of sewer in the town.
3. The direct communication of houses with sewers must be interrupted, and an efficient independent system of ventilation applied to every house drain.
4. Means of flushing must be provided, such as shall not endanger water services.
5. There must be a separation of all water pipes from immediate connection with sewers.—*British Medical Journal*, May 20.

Cancer of the Pylorus.—Dr. Hutchinson, of Philadelphia, reports a case of cancer of the pylorus in which great relief followed the washing out of the stomach according to Kussmaul's plan, with a solution of a drachm of bicarbonate of sodium in a quart of water. Before this treatment was adopted the patient vomited after every meal, and occasionally a simple change of position would be sufficient to cause vomiting. Oxalate of cerium, bromide of potassium, restriction of the diet to milk and lime-water, and even feeding by the rectum, had been tried in turn, but nothing seemed to control the vomiting. From the time, however, that the stomach-pump was first employed until the patient's death, a period of rather more than seven weeks, vomiting occurred only twice, or at most three times. During this time she was able to take food freely, and was rendered so much more comfortable by the treatment that she begged for its continuance herself. Wyman's stomach-pump was the instrument used at first, but its manipulation required so much time that a Thudichum's douche was soon substituted for it. The rubber pipe of the douche was attached to the tube that was introduced into the stomach, and the alkaline solution allowed to pass into the stomach by its own gravity. While the tubes were still full the bottle was suddenly depressed below the level of the patient's body, and the india-rubber tube was detached from it, a siphon being thus formed through which the contents of the stomach freely flowed. In this way the stomach was completely emptied. This was repeated two or three times at each sitting, without the slightest discomfort to the patient. The operation was at first repeated every day, but it was afterwards found that every other day was sufficiently often to prevent vomiting.

This treatment not only rendered the patient more comfortable, but it enabled a positive diagnosis to be made by diminishing the distention of the abdomen and the extreme irritability of the abdominal muscles. Previous to its adoption no tumor or induration could be felt in the abdomen even on deep pressure, but during the third *washing out* a hard body was felt to left of the median line just under the arch of the ribs, and this was found at all subsequent examinations.—*Philadelphia Medical Times*, May 27th.

Syphilis.—Dr. Thiry recommends the following treatment in old and obstinate cases of syphilis:

℞ Hydrarg. cyanuret..... gr. $\frac{1}{65}$
Ext. opii..... gr. $\frac{1}{6}$
Ext. guaiaci..... gr. iss. M.

To be made into one pill. One such pill is to be taken four times a day at equal intervals, and followed each time by a glass of some sudorific infusion.

On the Intra-venous Injection of Chloral.—In *Lo Sperimentale*, Fasc. 1, 1876, V. Chirone declares himself strongly opposed to the injection of chloral into the veins, as first practised by Oré of Bordeaux. He declares that it is often followed by phlebitis, and that in Bernard's laboratory he has seen animals die during the injection, from arrest of the heart's action in diastole. It may also produce dangerous symptoms from the power of chloral to coagulate albumen. He can see no reason for preferring the venous injection to the ordinary mode of administration.—*Allg. Med. Cent. Zeit.*, April 29, 1876.

Bent Knee, Eleven Years' Standing, successfully treated by an Operation.—Eleven years ago, Dr. Bent was called upon to treat a child three years of age, with acute inflammatory disease of the knee-joint, where there was inability to move the joint without pain. There was no cause assigned for the injury, so it was attributed to the constitutional condition. Antiphlogistic measures were adopted, but the inflammation became chronic, and counter-irritants with alteratives and tonics constituted the treatment, which was kept up for years, and the leg became flexed upon the thigh, with wasting of the muscles of the leg and thigh. The disease in the joint ceased about one year ago, but the limb was deformed and useless. At this time Dr. B. chloroformed the patient and divided the biceps tendon, and gradually straightened the limb; it was then flexed and allowed to remain in the position which it had held for so many years. The knee was bandaged, and retained in this position for eight days without any pain or swelling ensuing. Being placed under chloroform a second time, the leg was straightened again, with less difficulty than at first. It was then placed in a box, extending two-thirds on the thigh and beyond the foot, and secured by a broad bandage over the knee, and a narrow one at each end. It was retained in this position for two weeks; then the box was removed, and the knee bandaged, and the patient gradually put on her feet. She was, at last accounts, able to walk the streets with the aid of a cane, and the doctor thinks she will soon be able to use the limb without any artificial support.—*Canada Medical Record*, May, 1876.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, July 29, 1876.

THE HYGIENE OF RURALIZING.

At this time of the year, when half the population of our cities are ruralizing, a great many questions concerning the strictly sanitary advantages of the practice present themselves for consideration. The physician, when he advises his patients to go to the country, does not as often as he might appreciate the responsibility which he assumes. There are so many qualifying conditions to be taken into account in the choice of a locality, that it is not surprising that many mistakes are made; that patients, instead of improving, get worse; indeed, that the very change which was thought to be beneficial had a direct influence in hastening their dissolution. Some of the disastrous effects of this advice cannot be very well avoided in the absence of exact knowledge concerning the effects of climate on disease; but there are other drawbacks which are preventable and remediable, and to which, as medical men, we should give our attention.

We are of the opinion that there is not enough care taken to guard against the causes of disease which are now so generally recognized as associated with the unsanitary rural retreats. The time has gone by when the mountain side, the river shore, or the ocean beach is a synonym of health, and that a hap-hazard guess at the salubrity of these localities is always attended with good results. It has become the habit, however, with some medical men to consult the conveniences of their patients as regards localities, rather than rely upon a positive knowledge of the claims of the said locality as a health resort.

We have had within the past few years numerous examples of sickness in some of our most fashionable summer hotels, due to the neglect of the most ordinary sanitary regulations. When we consider this possibility in connection with large and expensive hotels, supplied "with all the modern conveniences," how much more will such a possibility of danger be exaggerated in the numerous farm-houses tinkered into the appearance of comfort and health, and overcrowded in the hottest time of the year by temporary boarders. The practitioners in rural districts have readily offered their testimony against these abominations, or so-called country boarding-houses; and numerous cases of preventable diseases occurring in them have come to our notice, due not only to overcrowding, but to culpable neglect of drainage, foul drinking-water, and other disease-engendering influences. So common is this condition of things, that it is becoming the exception rather than the rule to find these farm-houses even decently supplied with sanitary conveniences. When we add to this the risk of contamination of drinking-water, the frequent possibility of which has of late been so painfully impressed upon us, we become aware of the fact that a country retreat, far from being a health resort, may be the positive source of diseases which do not exist in the cities.

We have repeatedly alluded to the dangerous condition of some of the religious camping-grounds, so largely occupied during the warmer months. Although much has been done to prevent disease, much more is required before we can be assured that the longer these grounds are occupied the more dangerously saturated will the soil become. It was only a short time ago that provisions were made to guard against the sewage saturation of one of the largest of these camping-grounds. Until then, drinking-water was obtained by the sinking of pipes in a sandy beach, while holes in the sand were the only receptacles for the excrement. It is impossible to estimate how many cases of disease and death have been prevented by these means, the timely adoption of which seems almost providential. But many of these pilgrim picnic grounds are not in such a desirable condition, and the breaking out of camp fever, diarrhœal and other diseases, seems to be the merest question of time. The same remark applies with equal force and in a proportionate degree to many of the farm-houses, whose drains are badly cared for, and whose crowded condition intensify the risks of speedy soil contamination.

We can hardly be accused of magnifying the importance of attention to these matters, when we take into consideration the recent experiences in England. The history of the Eagley epidemic is still fresh in the recollection of many of our readers, and has directed attention to a source of disease which has been almost entirely overlooked. A great many of the temporary maladies which are popularly ascribed to change of water and change of air are quite explicable in the light of recent investigations, and are believed to be due to foul swamps and contaminated wells. Another one of the many difficulties which present themselves to the physician, in his attempts to properly advise in regard to change of air and change of place, is the fact that we possess too little positive knowledge concerning the laws which regulate the endemic influences

of certain diseases. So many of the old theories which we have held regarding the influence of locality and of altitude upon disease have been so entirely overthrown by the actual observations of experience, that any positive assurance of salubrity is the merest guesswork. Endemic diseases are found to propagate themselves under the most opposite conditions. Intermittent fever is not only found in the valleys and in the neighborhood of swamps, but at the very mountain tops; diphtheria is everywhere, and no locality can be said to be entirely free from typhoid fever. It is true defective drainage will serve to explain some of the relations between cause and effect; but that we have yet to discover some influences which are invariably present, and which always produce certain effects, is painfully palpable to every careful student of disease. We are making some progress in the right direction, it is true, and that we have reason to hope for the attainment of some more exact knowledge concerning the now hidden laws is an encouragement to study the subject with greater thoroughness and more enthusiasm. In the meantime, and in view of the many obstacles to the full benefits of ruralizing, it behooves us to exercise that care in the giving of advice as regards change of locality which our responsibility to our patients renders obligatory upon us.

THE FLOATING HOSPITAL OF ST. JOHN'S GUILD.

THE Floating Hospital of St. John's Guild has commenced its good work for the summer. Regular excursions are made for the benefit of the poor and sick children of the metropolis, and thousands of sufferers by this means receive the benefits of change of air and scene which could be obtained in no other way. Being aware that the design of the managers is to afford the greatest amount of aid and comfort to the suffering little ones which their means will allow, we cannot resist the temptation of again urging upon them the practicability of extending the time of their excursions over one day. In many cases a very transient benefit is gained to a sick child by a short excursion, and not infrequently the fatigue of the trip more than counterbalances its good effects. We admit that in order to supply a popular demand as large a number as possible should be accommodated, and that the benefits of the charity should be widely distributed; but it seems to us that some modification of their present plans could be made available without directly interfering with the interests of the majority. The suggestion which occurs to us to make in the interest of that class who need a change of air for a longer time, is that once a week, for two or three days at a time, the hospital should be anchored somewhere in the Bay, and for that time be, not only in name, but in fact, a floating hospital. These trips could be distinguished from the others, and set apart for that class of cases which might be most benefited by them. We believe that such a plan could be carried out with very little trouble and but little extra expense.

Reviews and Notices of Books.

DETERMINATION OF THE REFRACTION OF THE EYE BY MEANS OF THE OPHTHALMOSCOPE. By EDWARD G. LORING, M.D. From advance sheets on the Ophthalmoscope. New York: William Wood & Co. 1876. Pp. 61.

WHEN Ludwig Mauthner, then assistant to Professor Jaeger the younger, of Vienna, published his text-book of Ophthalmoscopy, the attention of the profession was reawakened to the value of the upright method in the use of the ophthalmoscope. We say reawakened, for, as Dr. Loring says in his opening paragraphs, "the very method first proposed by Helmholtz still remains by far the most beautiful, comprehensive, and truthful of all the means yet in our possession for the exploration of the bottom of the eye." Edward Jaeger, Stellwag, and others, continued to speak of the importance of this method instead of the examination by the reversed image; but there was no good instrument by which it could be practised for the detection of errors of refraction, until, in 1867 or 1868, when Dr. Loring modified Liebreich's instrument by the substitution of removable cylinders for the clip for holding lenses behind the mirror, these cylinders containing a series of convex and concave lenses which could be brought in front of the eyehole in the mirror. This instrument suggested all the other refraction ophthalmoscopes that have followed; that is, those of Knapp, Wecker, and Oldham. None of them have supplanted Loring's instrument, No. 9. While Wecker and Oldham have not been careful to give the credit that is due Loring for having invented the first Ophthalmoscope by which the determination of the refraction is made a comparatively simple matter, Oldham described his instrument, when he presented it to the International Congress of Ophthalmology, in London, in 1872, as a modification of Loring's instrument; but his printed description of it, published in the Transactions of that body, on page 119, would not allow any one to know that the foundation for his slight, and to our mind useless modifications, were only to be found in the American instrument.

Again, Wecker, in presenting a new optometer to the Heidelberg Congress of 1875, *Zehender's Monatsblätter*, October, 1875, p. 458, does not mention Dr. Loring's instrument. We notice these things in the RECORD in order that our English and French friends may see that we are not entirely ignorant of the claims of our own authorities.

After a description of his ophthalmoscope, as well as of the modifications of Knapp and Wecker, Dr. Loring presents a clear and comprehensive account, in a very readable style, of the principles upon which the determination of the refraction of the eye depend. The reader of the 6th chapter of Mauthner's text-book will not find in this account a great deal essentially new, but those to whom the German language is not accessible will get in Dr. Loring's chapter an invaluable assistance to the fascinating study of the measurement of the refraction of the eye, a study first made really practicable by the author's ophthalmoscope; and we say this mindful of Jaeger's personal teaching on the value of the upright image. We shall look with great interest for the complete book of which

these are advance sheets. As it is, we know of no other work, or monograph, or chapter in a text-book in our language which supplies the place of the book we have been reviewing.

Reports of Societies.

AMERICAN MEDICAL ASSOCIATION.

Section on Practice of Medicine, Materia Medica, and Physiology.

In the absence of Dr. F. G. Smith in Europe, Dr. Joynes, of Richmond, Va., was chosen Chairman *pro tem.;* Secretary, Dr. B. A. Vaughan, of Miss.

Clinical and Meteorological Observations in the Study of Ætiology.

On the first day, Tuesday, June 6th, a Report was presented from Dr. N. S. Davis, of Illinois (unavoidably absent from the meeting), on the "Necessity for Coincident Clinical and Meteorological Observations and Records in the Study of Ætiology." The interest of active practitioners in some of the Western cities had been enlisted, but the Committee were not prepared to make any report. The Committee (Drs. Davis, J. B. Johnson of St. Louis, and H. A. Johnson of Chicago) were continued.

Extract of Malt.

There being no regular papers ready for presentation, Dr. F. H. Davis, of Illinois, offered some brief notes on "Liebig's Extract of Malt, and its Chemical Composition, Manufacture, and Therapeutical Uses." Dr. Squibb, of New York, being called upon for his views on the subject, alluded to the important part played by genuine diastase as a fermentable element. And yet how do we know that what the merchant or druggist calls diastase is such? At best it is a variable substance, that cannot be secured from material changes.

Treatment of Phthisic without Whiskey.

Dr. Palmer, of Michigan, agreed with Dr. Davis in his views as to the treatment of pulmonary tuberculosis in various stages without whiskey. After alluding to the different forms of consumption, he stated that he had met with the slow chronic variety of the disease, commencing with the inflammatory process throughout, more frequently in drinking men than in any other class. He also referred to the happy influence of opium and quinine in the early stages of the disease.

Dr. Angear, of Iowa, alluding to the production of sugar by the liver, stated that in fœtal life, even prior to the formation of that organ, as soon as we recognize the presence of cells, we detect this peculiar sugar. In a wasting case of typhoid fever, in which the whole system of nutrition has been involved, we need something for the patient that will aid in the formation of cells. We may possibly get it from the malt, by converting starch into the peculiar saccharine condition required, which may afterwards enter into the formation of oils and fats necessary for the blood-corpuscles and the nervous system or for cell-growth. It is peculiarly adapted to the derangement of nutrition attendant upon phthisis.

Dr. Davis stated that with proper care malt could be made on a common cook-stove; that chemists and druggists could readily prepare their own. Diastase should be made fresh at the time it is needed. The physician should prescribe but a little at a time, let it be renewed frequently, and kept in a cool place. It is a difficult preparation to manage, but he would not do without it in his practice.

Dr. Squibb inquired whether he had ever used malt itself; it could be employed with the same effect as the preparation already alluded to.

Dr. Joynes inquired whether the addition of a little alcohol would not be of advantage to prevent the disintegration or change that might occur in the diastase.

Dr. Squibb doubted whether this addition would be desirable. It would be difficult to add enough to keep it from moulding without neutralizing the diastase.

Dr. Davis stated that the good effects of the malt would be lost if fermentation took place in it after it was taken into the stomach.

Concerning Pepsin.

Dr. Angear said that he made pepsin himself from the calf's stomach, and asked Dr. Squibb what proportion of wine should be used in making it.

Dr. Squibb stated that the best pepsin was that which a physician makes for himself from a pig's stomach, which is more analogous to the human stomach; the pig to be fresh from the slaughter-house, and, if possible, warm. Wash the stomach in a little water to separate the mucus and blood; chop it up with an ordinary chopping-knife in a wooden tray; bruise it; put it into a bottle and cover it with wine, not containing over seven or eight per cent. of alcohol, two pints of the wine to a stomach. Malaga wine is used on account of possessing this alcoholic strength. Sherry wine should be diluted with one-half water, as it contains sixteen per cent. of alcohol. If the wine should be too strong it would interfere with the action of the pepsin in the stomach. When we use two pints to a stomach we get only one pint of pepsin, for it will be absorbed by the pig's stomach; then another pint may be added. The whole stomach should be used. It would be difficult to get the mucous membrane by itself cleared from a healthy stomach.

The Chairman did not think this latter a very difficult process. He had been in the habit of making pepsin for a number of years.

Dr. Eilrich, of Pennsylvania, stated that his experience with malt had not been very favorable. Perhaps the causes of his want of success were accounted for in the suggestions of Dr. Squibb. After all, to get the proper effect of remedies in these cases, we must change the hygienic and other circumstances under which our patients are living.

Dr. Davis's paper was referred to the Committee on Publication.

Treatment of Pertussis.

On Wednesday afternoon the Section again met, when Dr. J. J. Caldwell, of Maryland, called their attention to the use of bromide of potassium and belladonna in pertussis, applied before the face, by Key's simple spray-producer, in such a way as to insure the patient's inhaling it. They are, he thought, specifics in this disease. Quinine should be administered when the disease has a malarial origin.

Dr. Ulrich was sorry the discussion had taken place at this time, as he wished to offer a paper upon it, containing facts collected by himself.

Dr.—— had faith in vaccination as a remedy of the greatest efficacy in this disease.

Dr. Donahoe, of Ohio, had employed vaccination for years. He referred to the cures that had been effected by merely taking children to the gas-works. A severe

case of pertussis in his practice had been cured by the supervention of measles.

Dr. Ulrich, in response to an inquiry, said he would re-vaccinate if the patient had already been vaccinated.

Dr. Van Dyke, of Kentucky, also approved of the counter-irritant effects of vaccination.

Dr. Yandell, of Kentucky, believed that as a remedy it was impracticable. It was like giving garlic to a man who was fond of onions to take away the offensiveness of the latter.

Dr. Ulrich differed with the gentleman from Kentucky in his views as to the efficacy of counter-irritation in these cases.

Dr. Angear thought that as this was a nervous disease, any means which caused a discharge of the nervous influence should be resorted to in order to produce a subsidence of the disease itself. Chloroform, for instance, acted by bringing about a discharge of the nerve force.

Dr. Ulrich said that chloroform only abated disease, while vaccination was claimed to be curative.

ARSENIC IN SKIN DISEASES.

Dr. L. D. Bulkley, of New York, then read an interesting paper on the "Uses of Arsenic in the Treatment of Diseases of the Skin." He endeavored, while warning against a routine prescribing of the medicine, even in diseases in which it is of service, to show the real power which it possesses over cutaneous disease, taking issue with those who have neglected or decried its use; who, he thought, were influenced by the more rapid and in some instances now brilliant results of local treatment, which latter, in Dr. Bulkley's opinion, could not be obtained in the run of general practice by those not particularly familiar with this branch.

In demonstrating the controlling power of arsenic over eczema, he narrated cases where children and even young infants took the drug (with no other treatment) in increasing doses up to a quantity above that given commonly to adults, and that for months, not only with the cure of the disease, but with improvement to the health; and by frequent reference to other authors he showed the harmlessness of arsenic in medicinal doses, even when continued a long time.

A particular point in the paper was the introduction to use in this country of the old English preparation. De Valangin's solution of the chloride of arsenic, as more suited to the stomach. This has been recently introduced into the United States Pharmacopœia under the title of *Liquor arsenici chloridi*, which is of the same strength as Fowler's solution, or three times that of the old De Valangin's.

The indications and rules for the administration of arsenic were detailed; the diseases given in which it is of service, also those in which it is valueless.

On motion, a vote of thanks was tendered Dr. Bulkley, and his paper referred to the Association for publication.

Dr. Yandell alluded to struma and malaria as the two great causes of disease, and to the remedies applicable in each, especially in cutaneous affections. He believed that arsenic was a valuable agent in chronic forms of eczema. He was surprised at the large doses reported by Dr. Bulkley, especially for children. He was in the habit of giving arsenic in doses of one, two, or three drops of the solution in some tonic or water, and did not ordinarily deem it necessary to increase the dose.

Dr. Ulrich thought that Dr. Yandell attributed too much to malaria in these local or cutaneous diseases.

Dr. Yandell stated that he seldom used arsenic if the case was malarial; he administered quinine.

Dr. Ulrich said that arsenic given for a length of time to beautify the skin, or to a horse to improve its appearance for sale, ruined the system, and soon left the person or the animal languid and weak. He was surprised that such an effect of arsenic on the human system had not been alluded to by Dr. Bulkley. He was not satisfied that the Section should endorse everything that gentleman had said, but the paper was well worthy of publication and diffusion.

Dr. Octerlony, of Kentucky, thought the previous speaker overestimated the danger of medicinal doses of arsenic. Many arsenic-eaters are long-lived and enjoy good health. Dr. Yandell had attributed more to the influence of malaria than Dr. Bulkley or himself were disposed to admit. Dr. Bulkley's paper was, he thought, earnest, elaborate, careful, and the result of patient labor and thorough research. The solution of arsenic mentioned by Dr. Bulkley was weaker than Fowler's solution, and yet, given in the same doses as the latter, Dr. Octerlony found it to produce identical effects. He had found large doses of Fowler's solution do good to children with cutaneous affections, when smaller ones produced no effect. This rule is not an invariable one, however.

Dr. Duer, of Philadelphia, stated that some of the English dermatologists favored the use of large doses of arsenic. His own experience had been favorable to small doses, if given for any length of time. He was surprised that Dr. Bulkley had been able to administer such large doses successfully. He rarely prescribed arsenic to children.

Dr. Yandell thought that observations on the effects of arsenic might be made by physicians on themselves and on their medical students.

Dr. Angear asked what evidence there was that arsenic will contract the blood-vessels. Quinine has this effect, and may not the influence of the two drugs in skin diseases be connected with this point?

Dr. —— thought the dose of arsenic should be decided by the individual experience of every gentleman. Many of the guides and hunters and burden-carriers of Styria were found to be consumers of immense quantities of arsenic. Some of them were over eighty years of age, and had taken the drug for more than half a century.

THE NEW PHARMACOPŒIA.

On Thursday afternoon, Dr. Squibb acted as temporary Chairman, and at the request of several of the gentlemen present gave his views in regard to the next revision of the United States Pharmacopœia, allusion to which has already been made in the Record (June 17th, p. 395). The plan for the last fifty years had been for the delegates of the colleges to meet in convention, and appoint a committee of revision, who performed the labor and published the work. Wood, Bache, and Carson were either dead or would be prevented by ill health from laboring in the cause of the next revision. There was danger that it would go over to the commercial interests of pharmacy. The American Medical Association and the American Pharmaceutical Association should be more fraternal, or at least recognize each other more fully. They should come together on the subject of the Pharmacopœia, as their interests were mutual. The Army and Navy Medical Services should also be represented in this pharmaceutical council. Two editors should be appointed, one for the materia medica list, the other for the preparations, under the supervision of the Council. The Convention wished a Pharmacopœia based on general principles,

but the Committee did not like those general principles, and cut adrift from the Convention. Much time and labor was spent on it, but it was not the Pharmacopœia the Committee wished. The volume was one sought after by booksellers as a source of profit. What they paid for the privilege would compensate the editors and pay all expenses. The national associations need not be at any expense. He would bring the matter before the next annual meeting, as in Philadelphia any new plan would probably meet with opposition.

The Secretary of the Section urged the desirability of bringing this matter to the attention of the Association at once, instead of postponing it for a year.

Dr. Squibb then read the resolutions already referred to (p. 395), and, by general request, agreed to remain over to present them to the Association on the following morning, as the sentiment of the Section on the subject.

Dr. Elerich hoped the matter would be thoroughly agitated in the medical and pharmaceutical journals of the country.

ON CHOLERA.

Dr. Henry R. Rogers, of New York, then read an interesting paper on "Cholera; its Origin, Nature, Causes; Dissemination by Contagion, by Portability, and by Epidemic Influence; its Pathology, Microscopic Appearances, Treatment, etc., etc."

Dr. Thomas W. Foster, of Kentucky, stated that he had been through three epidemics of the disease. Want of success in treatment was often due to the fact that we slighted the early symptoms, and waited for treatment until prostration came. He thought that cholera was getting to be more sporadic than formerly.

Dr. Caldwell differed with Dr. Rogers in the view that early treatment was an easy matter. Isolation of the cholera was very important. Much was to be expected from a rigid quarantine.

Dr. Ulrich thought the laws of epidemics were as fixed and immutable as the laws of growth and reproduction. We have all the facts, and should know the proper treatment of this class of diseases. Dr. Foster of Nashville had told him that when a young man he rode forty miles to a village to see some cases of cholera for the first time. Here he heard two farmers discussing the subject, one contending that it was infectious, the other that it was contagious. Not being able to settle the point, they appealed to a third party, and asked what he thought about it. "Well, boys," said he, "it's a matter that's bothered me very much; sometimes I've had the opinion it's contagious, and circumstances have come to my mind that made me think it was infectious. One thing's certain; the damned thing's catching." Dr. Ulrich classed cholera among the neuroses. The influence of the mind in the spread of the disease was marked.

Dr. Rogers detailed several interesting cases of cholera, and the treatment employed, which may be briefly given as follows:—1. Acetate of morphia administered hypodermically. If no urgency, other remedies and other methods; opium and its preparations being preferred. 2. Horizontal position, with the head as low as the body, or lower. 3. Finely-powdered ice, *ad libitum*, for the mouth, or coldest water procurable in absence of ice. 4. External heat, frictions, etc. 5. For fever of reaction,—gentle opiate influence to be kept up, and remedies directed to the restoration of the action of the kidneys. 6. For collapse,—position, external heat, and frictions, and such internal use of nutriment and stimuli by the mouth and by enemata as may be judiciously employed. 7. After-treatment for restoration of wasted forces. Dr. Rogers dwelt particularly upon the happy and speedy influence of the hypodermic application of the morphia, which acted almost as a specific.

The paper of Dr. Rogers was then referred to the Committee of Publication.

After remarks by Dr. Curtis, of Michigan, on cases of cholera in St. Louis and Chicago, the condition of the blood-vessels in that disease, its neurotic character, etc., the Section adjourned *sine die*.

Correspondence.

MEDICAL CENTENNIAL AFFAIRS.

THE BUREAU OF EDUCATION—THE DEPARTMENT OF AGRICULTURE—VETERINARY SURGERY—CENTENNIAL MEDICAL HOSPITAL.

(From our Special Correspondent.)

PHILADELPHIA, July 22, 1876.

In addition to the exhibits made by the Medical Services of the Army and Navy in and near the United States Government building already described, the Department of the Interior presents in its Educational, Indian, and Agricultural Bureaus many interesting medical features. The Bureau of Education, under charge of Commissioner John Eaton, is a sort of central agency for the collection, preservation, condensation, and distribution of the general educational statistics of the whole country. It will thus be seen that it is not a controlling power, but that it merely gathers up for permanent record the results of the labors of others. If, as we learn is the fact, the Bureau, among its numerous duties, is compelled to analyze the annual catalogues, etc., of schools of divinity, law, *medicine*, and science, selecting from each what is worthy to be noted in the way of either improvement or defect, we fear that its labors are scarcely rewarded in the little of novelty that it gleans as to the progress of medical education from year to year. It annually corresponds with ninety-eight schools of medicine, but what information it obtains beyond the mere numerical statistics we are at a loss to conjecture. The only document of a purely medical character the Bureau has yet published is the contribution made by Dr. J. M. Toner, in 1874, to the annals of medical progress and medical education in the United States before and during the war of Independence. In its exhibit at the Exposition of the illustrative apparatus associated with medical education, the display is of rather a meagre kind, and gives but a faint idea at the appliances employed in first-class medical schools in the elucidation of anatomical or physiological facts. But we can scarcely expect anything more elaborate from a Bureau which has so many interests under its charge, and in the necessarily limited space assigned it is unable to make a specialty of any one of its departments. It has the appearance, however, of having temporarily borrowed for centennial display some of the apparatus and models of a surgical instrument-maker to cover up its own deficiencies, for we find in the two large cases assigned to this portion of their exhibit cards which read as follows:—"Borrowed from John Reynders & Co., 309 Fourth Avenue, New York." In the cases are diagrams of skeletons, papier-maché models, dissecting instruments, the original transfusion apparatus and its improved modern successor, the handsome transfusion

instrument of these later days, as well as that of Dr. Fryer. Near these is an explanatory paper for the benefit of the unenlightened public, who might otherwise gaze wonderingly at an apparatus of whose uses they were wholly ignorant. From it they learn that transfusion is one of the oldest operations on record, having come into prominent notice during the latter part of the fifteenth century, when the physician of Pope Innocent VIII. sacrificed three boys in performing the operation on his master, without saving the latter's life. It mentions the names of some of the Europeans who have performed the operation, and those of Flint, Morse, Thomas, Emmet, Fryer, and Stowe as having resorted to it in this country. A printed circular is also displayed, explanatory of the mode of employing the apparatus.

In another case this Bureau exhibits immense models of teeth, illustrative of dental physiology and anatomy, skulls, sectional views of the brain, etc. Chemistry and physics are represented by microscopes, test-tubes, a set of weights and measures exhibiting the peculiarities of the metric system, made by J. L. Hammett, of Boston, and a metric diagram by A. and T. W. Stanley, of New Britain, Conn. The Philadelphia College of Pharmacy is preparing a case to display the educational resources of that special department of instruction.

In the same case as that occupied by the reports of the deaf and dumb institutions of the country I notice certificates and reports of the Training School for Nurses attached to Bellevue Hospital, New York, near which is a framed photograph of the graduating class of this school, seven in number, of the spring of 1876. It would be like carrying coals to Newcastle to quote the facts detailed in this report, which demonstrate the great success of what was three years ago only an experiment, by which from good women, healthy in body and mind, are trained nurses who will carry the best kind of help and comfort to the bed-sides of the sick and suffering. Were this a report of any other institution than the one so locally familiar to many of the readers of the RECORD, I should be tempted to quote from its pages a paragraph or two, for the benefit of the profession, laudatory of the hospital training given in this school, which, in the phraseology of the Report, is synonymous with calmness, exactitude, quick observation, and implicit obedience to the doctor's orders.

The Department of Agriculture embraces a miscellaneous collection of soils, fertilizers, fossil bones, seaweeds, guano, grains, fruit, wines, etc. It would seem a hopeless task in such an *omnium gatherum* of useful and indispensable articles for the keenest reporter or interviewer to search for medical items; but in a solitary case are exhibited many indigenous articles of the materia medica, and numerous active principles in the daily routine of prescribing familiar to the profession. Here are jars and vials of stramonium seeds, flax-seed, black root or leptandra Virginica, veratrum viride, gelseminum, etc.; of sanguinaria, podophyllin, veratroidia, daturia, berberina, etc.

The only matters of professional interest in the War Department exhibit, but a few steps from those just described, are such as relate to the anatomy and pathology of the horse, so far as they concern his hoof. The veterinary surgeon must experience a high degree of satisfaction at the elaborate display made by the Government of injected preparations showing the arteries, veins, nerves, and tendons of the leg of the horse; of hoofs exhibiting the diseases arising from improper shoeing, superfluous growth, extraordinary enlargements with anchyloses of the os suffraginis, fractures, bony spavin and splint, etc. The Society for the Prevention of Cruelty to Animals possesses a most valuable adjuvant in the argument thus offered by the Government in favor of the proper treatment of the feet of this useful animal.

Leaving the Government building for the present, we may direct our steps to the head of Lansdowne Ravine, at which has been established the Centennial Medical Hospital. This building is intended for the temporary accommodation of all cases of sickness or injury that may come to it for treatment. Since it was opened, less than two months ago, between four and five hundred transient cases have been treated, none of which are allowed to remain over night. Machinery Hall has supplied its quota of mashed fingers, and the restaurants have added to the statistics of burns and scalds; but we are still far behind the Exposition at Vienna, in which a hospital similarly arranged is said to have averaged three cases of labor daily. The medical staff will doubtless find sooner or later that visitors to the Centennial will take advantage of the kindness and facilities thus offered to obtain gratuitous advice to which they have no claim. Dr. William Pepper, Medical Director, is in charge, with Drs. H. C. Wood, S. W. Gross, Curtin, Roberts, Osgood, Willard, and Herbert (Surgeon to the Guard), as his staff. A new tent hospital has just been opened for the guard, which body numbers eleven hundred men.

COOL BATHING IN THE TREATMENT OF INFLAMMATORY BOWEL AFFECTIONS DURING THE SUMMER.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—I beg to offer through your columns a method of treatment of bowel affections of children in the summer season, where fever is present. It has been so successful with me, that I am confident, if applied more generally, it would lessen very greatly the rates of mortality in the summer season. I allude to that form of disease which is denominated entero-colitis

Before we are called to these cases, tentative measures for the relief of the diarrhœa have already been applied by the friends, so that the inflammatory stage is generally fully developed when we first see the patient. The skin is hot (temperature 102½° to 105°), the pulse rapid (130 to 150), respiration 30 to 50, with frequent purging of semi-fluid, greenish, watery, fecal, and half digested matters; the mouth and tongue are dry; the thirst intense, but the water taken to slake it is quickly thrown off; the eyes are staring; pupils contracted; insomnia and rolling of the head, with utterance of distressing cries, due to headache from hyperæmia of cerebral vessels and unappeased thirst. Such is a general statement of the symptoms.

I at once proceed to give the little sufferer a bath in hydrant water, which with us, in summer, is about 75°. I have found it necessary to give this my personal attention at first, because the mother or friends will not carry out instructions, on account of the cries and resistance of the child; it seems to them a great cruelty.

The contact of a hot skin with cold water is certainly painful for the moment, hence I immerse the body from legs upward gradually, sponging the skin in advance, so as to obtain tolerance.

When the body and extremities are fully under, holding the head in the palm of my left hand, I pour over its surface cooler water, such as cistern water, which is here about 65°. This is kept up for ten or even fifteen minutes. Meanwhile the child

ceases to cry or struggle, and is evidently greatly comforted; more especially when cool water is freely given to drink,—the greedy swallowing of which shows how much of its distress is due to thirst.

After the bath the patient should be wrapped, unwiped, in a light woollen shawl, and laid upon its bed, with a slight additional covering. The pulse has lost frequency, but is quite feeble; the breathing is slower and the skin quite cool, even bluish in hue. The sedation may seem at first too great; but reaction soon begins, a healthy warmth and perspiration are established, and the child falls into a peaceful sleep. The scene has so changed that one will find no difficulty thenceforth in getting a bath given three or four times in twenty-four hours, if the alarming train of symptoms make show of revival; and they will revive to such an extent as to require exhibitions of the bath from time to time for two or three days perhaps; for the diseased state of the mucous membrane within has not been as suddenly relieved as the abnormal heat of the body.

In the meantime internal remedies should be freely employed. Quinine, whiskey, beef-tea, milk, and lime-water are the chief agents. One grain of quinine and a drachm of whiskey every three hours, for a child eight to sixteen months old, looks rather formidable, but they will be found admirable while the disposition to fever lasts.

Subsequently bismuth and pepsin are of great value to restrain diarrhœa and to assist digestion, so greatly at fault owing to the blow which the mucous membrane has suffered.

C. G. Comegys.

Cincinnati, Ohio.

A SIMPLE METHOD OF OBTAINING DEPOSITS FOR MICROSCOPIC EXAMINATION.

To the Editor of The Medical Record.

Sir:—In certain cases, where the deposit in urine or other fluid is scanty, the difficulty of obtaining a satisfactory specimen for examination is so great that I am induced to publish the following simple device, in the hope that it may prove as useful in other hands as it has been in mine during the past year.

To a piece of glass tube, six inches long and three quarters of an inch in diameter, one of the thin glass covers for microscopic slides is attached by means of an india-rubber ring (a bit half an inch long, cut from elastic tubing about half an inch in diameter) so as to form a movable bottom. If the suspected liquid be allowed to stand in this extemporized vessel for a few hours, all sedimentary matters must, of course, settle upon the thin glass disc, which, after the supernatant fluid has been carefully poured off (or withdrawn by a siphon), can be detached and reversed upon an ordinary microscope slide for inspection. If the elastic band be made to project a line or two beyond the lower end of the tube, its free edge may be readily everted to affix or remove the disc, which it embraces without leakage.

In this way casts and other anatomical or pathological elements, no matter how few in number, can scarcely escape observation, as they sometimes do in the usual methods of fishing for them. This plan is especially serviceable for the examination of sediments in potable water, which is ordinarily in too small quantity to be satisfactorily collected otherwise.

The idea is so obvious that it may possibly have occurred to some one before me; in which case I shall cheerfully yield priority of invention, contenting myself with the reflection that "*Les beaux esprits se rencontrent.*"

Alfred D. Carrol, M.D.

New Brighton, N. Y., May 27, 1876.

PRELIMINARY EDUCATION.

To the Editor of The Medical Record.

Dear Sir:—The Cayuga County Medical Society desires to record its name with those of Erie and Ulster Counties as one who insists on a preliminary examination of all persons desirous of commencing the study of medicine under the supervision of any of its members.

At a regular monthly meeting of the Society, held July 12th, 1876, the following resolution was unanimously adopted:

Whereas, the profession of medicine, in its breadth and scope, requires the amplest preparation and most careful training to properly enable the practitioner to fulfil its many requirements; be it

Resolved, that it is the judgment of this Society that all persons who may desire to pursue the study of medicine and surgery in the office of any physician of this Society, shall submit himself or herself to an examination in branches preliminary to that study.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from July 16th to July 22d, 1876.

Swift, E., Surgeon. Leave of absence extended two months. S. O. 142, A. G. O., July 14, '76.

Perrin, G., Surgeon and Medical Director. Granted leave of absence for one month, with permission to apply for an extension of ten days. S. O. 140, Dept. of the Missouri, July 10, '76.

Clements, B. A., Surgeon. Assigned to duty with Big Horn Expedition in the field. S. O. 98, Dept. of the Platte, July 17, '76.

Byrne, C. C., Surgeon. To proceed without delay to mouth of Big Horn River, M. T., and report to Brig.-General Terry for duty with his command in the field. S. O. 86, Dept. of Dakota, July 19, '76.

Kimball, J. P., Asst. Surgeon. To accompany battalion of 22d Infantry under Lt. Col. Otis, to mouth of Big Horn River, and upon arrival there, report to Brig.-General Terry for further instructions. S. O. 83, Dept. of Dakota, July 12, '76.

Harvey, P. H. F., Asst. Surgeon. To accompany battalion of 22d Infantry under Lt. Col. Otis, to mouth of Big Horn River, and upon arrival there, report to Brig.-General Terry for further instructions. S. O. 83, C. S., Dept. of Dakota.

Semig, B. G., Asst. Surgeon. Leave of absence extended one month, with permission to leave limits of this division and apply for a further extension of one month. S. O. 96, Mil. Div. of the Pacific, July 7, '76.

Taylor, B. D., Asst. Surgeon. To proceed immediately to mouth of Big Horn River, Mon. T., and report to Brig.-General Terry for duty with his command in the field. S. O. 85, Dept. of Dakota, July 17, '76.

Lord, Geo. E., Asst. Surgeon. Missing in action with Sioux Indians on Little Big Horn River, Mon. T., June 25, '76.

July 22.....	0	6	21	3	13	25	8

The Treatment of Sun-stroke.—Dr. Charles Bliss writes as follows: I wish to call the attention of the profession through your columns to a method of treating sun-stroke which I have found very successful. Without entering into any discussion of the etiology of the disease, or the pathological conditions present during an attack, I will only say that, as a condition of success to any treatment, it must be applied before the patient's temperature has reached a point that is incompatible with the continuance of life, viz., 108° or 109° F. When called to a case of sun stroke we usually find the patient nearly if not quite unconscious, with stertorous breathing and generally complete muscular relaxation. In this condition he should be taken into the open air, his outer clothing removed, and his head slightly elevated. Cold water (not ice water) should then be poured freely over all parts of his person until his temperature is reduced to the normal standard. (Where a bath-tub is at hand it is to be preferred.) The application of ice to the head is of no benefit; the free use of water at its ordinary temperature accomplishing much more efficiently the general abstraction of heat from the patient's body. When consciousness is restored, which usually occurs in a very short time, the patient should be dried with moderate friction, removed to bed, and covered with only a sheet or very light blanket. A light liquid diet, with, if necessary, a mild saline aperient, will usually complete the cure in a few days. The use of stimulants is seldom necessary. Freely douching with cold water is as applicable to the lower animals when suffering from sun-stroke as to man. One of our largest street railroad companies has for many years past lost great numbers of horses every summer from this cause. This year, by my advice, the superintendent has adopted the plan of promptly douching with a stream from the hydrant every horse affected. So far the success has been complete; but one horse having died out of a great many attacked, and that one not having been subjected to the treatment. The main point in all cases is to apply the water promply and freely. [Although this plan of treatment is not new, it is nevertheless good.—Ed.]

Preliminary Education in England.—At the recent meeting of the English General Medical Council, Dr. Haldane gave the following account of the qualification of the usual candidate for medical college matriculation:

"In Edinburgh the standard for the preliminary examination was the minimum fixed by the Council; for obligatory subjects there were English, Arithmetic, Algebra, Geometry, and Latin; the optional subjects, of which the candidate was to take one, being Greek, French, German, and Natural Philosophy. This certainly was not too high a standard, but it was a melancholy fact that a very small portion of the candidates were able to pass this examination on the first occasion. The knowledge of English could only be said to be moderately satisfactory, and a certain number of candidates were rejected every year for deficiency in spelling. In Latin the deficiency was positively deplorable, not more than twenty or twenty-five per cent. passing on the first occasion. Two of the optional subjects—viz., Greek and German—were very seldom chosen, but the students selecting them generally passed. In French and natural philosophy the result was different, as he noticed that students often had a sort of smattering on these subjects. These results clearly showed that the knowledge of candidates was very deficient, and pointed to a comparatively low state of the preliminary education of the country. How it happened that candidates were admitted upon the Register who had such very deficient preliminary knowledge he did not propose to explain. He did not believe it was from any wish on the part of the different bodies to evade the directions of the Council, but rather from a sort of desperation. The candidates who appeared were often so bad that the examiners felt, if they rejected every man who ought to be rejected, comparatively few would be allowed to study for the medical profession. Be this as it may, there could be no doubt of the fact to which he alluded. The remedy was in the elevation of the general education of the country, but with that the Council could not interfere. The only other plan was to introduce the system of visitations that had proved so successful in the case of professional examinations; not that he proposed that the Council should send visitors to the different preliminary examinations, but that the different licensing bodies should, so to speak, visit one another. The object of his resolution was to recommend that in cases where candidates for professional examination displayed decided ignorance in general education, examiners should be requested to report on the matter to the bodies with which they were connected, and that those bodies should be recommended to transmit to the Council either the reports in question or a statement of the facts.—*Medical Press and Circular.*

Imperfect Drainage and Typhoid Fever.—Dr. Henry Flood, of Elmira, reports five cases of typhoid fever in one family, caused by imperfect drainage. When first called to attend the family (Mr. W.'s,) he made an examination to ascertain the cause and origin of the fever. In the rear of the house was a pool of water which extended to the rear of the house of a neighbor, Mr. G. Into this pond emptied a drain leading from a water-closet in Mr. G.'s house. Mr. G.'s privy was also situated on its banks, and there were also stables on its edges. In the summer this pond became stagnant and its drainage so imperfect that the water remained in it for months. After a heavy rain the water would flow back into Mr. W.'s cellar through a drain leading into the pond. During the summer of 1875 Mr. W.'s cellar was under water for nearly three months. In the fall of 1874 the father of Mr. G. was attacked with typhoid fever and died. The excrementa of the patient were thrown either into the privy over the pond, or into the water-closet, thus contaminating Mr. W.'s cellar water. Situated too between Mr. W.'s residence and this pond was a well for drinking water. This well was without doubt also contaminated, and the water was drunk by the persons who became subjected to the fever.

Original Communications.

THE THERAPEUTICS OF HEADACHE.

A LECTURE DELIVERED AT BELLEVUE HOSPITAL MEDICAL COLLEGE,

By A. A. SMITH, M.D.,

LECTURER ADJUNCT UPON CLINICAL MEDICINE.

(Phonographically reported by Dr. W. M. Carpenter.)

GENTLEMEN:—We take up to-day the therapeutics of certain forms of headache, a very important subject. Headache may be divided into organic and functional; but I believe you will get a better idea of the treatment by dividing the cases according to the causes.

You will remember we took up purely neuralgic headache at the last lecture.

A headache, when due to nervous disturbance, such as occurs in hysterical or excitable subjects, if associated with plethora, often yields to a saline cathartic. The most agreeable is the solution of citrate of magnesia, and should be given, a full bottle of it, on an empty stomach. In addition, it is well to give one of the bromides combined with valerian. The following prescription I frequently use:

℞ Sodii bromid..... ℥ vi.
Elix. valer. amm..... ℥ iv.
M. Sig. ℥ i. every hour until relieved.

If such nervous headache be associated with anæmia, after relieving the immediate attack with the bromide and valerian prescription, give iron, and give it for weeks, until there is a decided improvement in the patient's condition. Always give the iron after meals. In these anæmic cases it is often advisable to stimulate the heart's action. For this purpose I have found the following useful:

℞ Amm. muriat..... ʒ ss.
Tinct. actææ racemos.,
Aquæ.....āā ℥ iij.
M. Sig. ℥ ij. after meals in a wineglass of water.

If there be despondency and depression of spirits, phosphorus, with nux vomica, is a good combination. The unpleasant taste of the phosphorus has been overcome by being made into sugar-coated or gelatine-coated pills. I frequently prescribe a pill containing phosphorus gr. ¹⁄₁₀₀, with ext. nux vomica, gr. ¼ t. i. d., with the happiest results. These pills can be obtained of any reliable druggist. This despondency is apt to occur in those who have been overworked mentally, or are harassed by business cares, or who suffer great mental anxiety. If in addition to these symptoms there be sleeplessness, I employ the following pill:

℞ Camph. pulv.....gr. xxv.
Ext. cannab. ind.....gr. x.
Ext. hyoscyami.....gr. xx.
M. Div. in pill No. x.
Sig. One at night. Repeat in two hours if necessary to produce sleep.

It is important to attend to the general health of the patient. Remove all causes of excitement; encourage exercise in the open air; let the food be simple but nutritious; let the sleeping room be large and well ventilated; in short, let the patient be surrounded by the best possible hygienic influences. These general remarks will apply to almost all forms of headache.

SICK HEADACHE.

I usually recognize two forms of sick headache (so called), the one neuralgic in character, as hemicrania and trifacial neuralgia, the other a dyspeptic headache. In the neuralgic variety the pain in the head precedes the nausea, while in the dyspeptic variety the pain in the head succeeds the dyspeptic symptoms. In the neuralgic, vomiting does not relieve the pain, while in the dyspeptic an emetic or laxative often relieves the pain in the head by removing the cause. In addition to the treatment given in a previous lecture for neuralgic headache, which often occurs at intervals of a few days, or a week or two, sometimes coming on at sunrise and disappearing at sunset, I have good results from the use of guarana, or paullinia sorbillis as it is sometimes called. I give it usually in powder, grains fifteen every fifteen minutes, until six doses have been taken. It is best given in a little sweetened water; and if six doses do not relieve, do not continue it; it will probably not relieve. It is well to give these powders in any headache (not malarial) of long standing and prone to return at certain intervals.

MALARIAL HEADACHE.

Malarial poison may produce pain in any portion of the head, but the most frequent locations are the sub occipital region, the frontal, and on either side (hemicrania). Begin your treatment by the use of quinine. If distinctly periodical, give ten or fifteen grains two or three hours before the expected attack. It may be necessary to push the quinine in divided doses until cinchonism is produced, and kept up for several days, and then gradually diminish the dose. If the pain still continues to recur, and it frequently will, resort to arsenic and belladonna, five-drop doses each of Fowler's solution and tincture belladonna, after meals, increasing the Fowler's one drop each day until œdema arsenicalis is produced. This will seldom fail to give relief.

I have found the following prescription beneficial in a headache dependent on gout:

℞ Vin. colch. sem..... ℥ iij.
Lithii bromid..... ʒ ss.
Syr. zingib..... ʒ ss.
Aq. cinnamonii, q. s. ad..... ℥ vi.
M. Sig. ʒ ss. in a tumbler of Vichy water every four hours.

Such patients will be benefited by the regulation of the hygiene, tonics, a partial discontinuance of stimulants, particularly those which have been found by experience to aggravate the gouty symptoms.

It is hardly necessary that I should tell you that the headache of syphilis is more severe at night, and is quite apt to awaken the patient after twelve by its increasing severity. The use of calomel in one-tenth grain doses every hour, for twelve hours immediately preceding the time that it awakens the patient, gives more rapid relief than the ordinary constitutional treatment. The calomel treatment may be continued for two or three days, and then stopped and iodide of potassium given. I usually begin the iodide in fifteen-grain doses after meals, and gradually increase it until iodism is produced or irritation of the stomach occurs, provided the symptoms do not yield earlier. It may be necessary to push it to 350 or 400 grains a day before the symptoms yield.

The headache of rheumatism is characterized usually by tenderness of the scalp, which is increased on pres-

sure or motion. Use the mild faradic current on the scalp, and internally the following:

℞ Potass. iodide,
Amm. muriat. āā ʒ iss.
Infus. humuli. ʒ vi.
M. Sig. ʒ ss. four times a day in a wineglass of water.

In some cases of rheumatic headache, which have not yielded to the above treatment, I have found bromide of ammonium in twenty-grain doses every two hours effectual.

There is another form of headache which is of great importance as a symptom of serious disease. The pain in the head may be the first evidence you will obtain that there exists renal disease, and that you really have to deal with uræmic headache. The judicious plan of treatment in such cases has for its object the removal of the abnormal amount of urea from the system. To accomplish this, you may call into action one or all of the three great emunctories of the body, the kidneys, the intestines, and the skin. Make the kidneys act if you can; apply dry cups over the region of them, and give internally the following:

℞ Potass. acetat. ʒ vi.
Infus. digitalis. ʒ vi.
M. Sig. ʒ ss. q. 3 h.

The infusion should be made from fresh English leaves. Give this until the kidneys act freely, if you can make them do it within twenty-four hours. You cannot always rely on this, however. If the kidneys do not act freely, and the headache is not relieved within twenty-four hours, give a saline cathartic. A treatment almost domestic, and often very effectual, is to put an ounce of cream tartar in a quart of water, and have the patient drink this in eight or ten hours. It acts both as a diuretic and cathartic. Do not use hydragogue cathartics unless convulsions are threatened, they are too irritating to the intestinal canal. Some prefer to eliminate the urea by the skin. This can be done by diaphoretics and the hot, moist, or dry air bath. Do not think that you must use diuretics, cathartics, and diaphoretics in all cases of Bright's disease; use them where there is deficient quantity of urinary secretion, and where you have reason to believe urea is accumulating, and that you can relieve the patient by ridding the system of it. There are other causes of headache in Bright's disease which I believe occur independent of the presence of an abnormal amount of urea in the blood, and yet which are dependent on the results of the kidney disease. These causes may be anæmia, neuralgia, œdema of the brain itself, serous effusion into the ventricles, and, in acute Bright's disease, or cerebral congestion in addition to accumulation of urea. Under the last condition, if the headache be very severe and convulsions threaten, take blood, if the patient's condition will admit of it. Take twelve to twenty ounces, if necessary to relieve distressing symptoms. The best way to take it is by means of wet cups over the region of the kidneys.

If the patient be anæmic, improve the general condition by the use of tonics, good nutritious diet, stimulants, exercise in the open air, etc.

If the headache be dependent on serous effusion into the ventricles, or on cerebral œdema, here too improve the vitiated condition of blood and stimulate the heart and kidneys by potass. acetate and infus. digitalis. There is apt to be with this effusion and œdema general anasarca.

The headache of acute alcoholism, or inebriety, follows a debauch. The first indication is to remove the alcohol from the intestinal canal. For this give of rhubarb and magnesia calcined each a half drachm, and then give the following:

℞ Spts. amm. aromat. ʒ ij.
Tinct. camph. ʒ iss.
Tinct. hyoscyami. ʒ iiss.
Spts. lav. comp. q. s. ad. ʒ ij.
M. Sig. ʒ j. q. 1 h. until the headache is relieved, and then give capsicum gr. ij. and quinine gr. iij. before each meal for several days. If there be sleeplessness, give

℞ Sodii bromid. ʒ ss.
Chloral hydrat. ʒ iiss.
Syr. aur. cort. ʒ ss.
Aquæ. ʒ iiiss.
M. Sig. ʒ ss. at night, repeat in two hours if necessary to produce sleep.

Dyspepsia is a frequent cause of headache.

If there is indigestible food in the stomach, and it has been there some time, give an emetic, as mustard and warm water, or sulphate zinc gr. xv., and remove it. If there is evidence of indigestible food in the alimentary canal beyond the stomach, give gr. xx. of rhubarb and magnesia each, and remove it from the bowels. If the headache be frontal, and the pain is located immediately over the eyes, give dilute nitro-muriatic acid in ten-drop doses, well diluted, after meals. If the pain is located about the roots of the hair, give an alkali before meals, as gr. xx. bicarbonate of soda or magnesia. The dyspeptic headache oftentimes is not confined to these regions, but spreads over the entire head. In such cases I combine an acid with an alkali, and add to these nux vomica, as in the following prescription:

℞ Sod. bicarb. ʒ iiss.
Ac. nitro-mur. dil. ʒ ij
Tinct. nuc. vom. ʒ iss.
Syr. aurant. cort. ʒ vi.
Aquæ, q. s. ad. ʒ vi.
M. Sig. ʒ ss. after meals in a wineglass of water.

If there be gastric pain, a mild counter-irritant, as a mustard plaster to the epigastrium, will often relieve the pain in the head as well as the pain in the stomach. If flatulence be a troublesome symptom, give the following:

℞ Bismuth subcarb. ʒ iss.
Tinct. nuc. vom. ʒ iss.
Tinct. card. co.,
Spts. lav. comp., āā q. s. ad. ʒ iv.
M. Sig. ʒ ij. before meals in a wineglass of water.

If there be constipation, the following pill may be given, one in the morning:

℞ Aloes pulv. ʒ ss.
Ext. nuc. vom. gr. v.
Ext. belladonna gr. iv.
M. Div. in pil. No. xv.

In some forms of headache associated with stomach indigestion I have found small doses often repeated of tinct. nux vomica effectual. I give a single drop every fifteen minutes, and continue this two or three hours if necessary. In other cases, where the headache comes on soon after a meal and seems to depend on delayed stomach digestion, large doses of pepsin are effectual. Give a half drachm saccharated pepsin in a wineglass of sherry wine, t. i. d., and let it be taken during meals.

Cerebral congestion as a cause of headache may be divided into two varieties, active and passive. These claim almost directly opposite plans of treatment. In

the active variety the patient should be kept in a darkened room, perfectly quiet, cold and evaporating lotions applied to the head. A saline cathartic may be given, and the following prescription:

℞. Sodii bromid ..... ℥ iiss.
Fl. ext. ergot ..... ℥ iiss.
Syr. zinzib ..... ℥ ss.
Aq. aurant. Flor. q. s. ad ..... ℥ iv.
M. Sig. ℥ ss. q. 2 h.

If the skin be hot and dry, and the pulse full and rapid, give Fleming's Tinct. Aconit. Rad. gtt. ii. q. 2 h. until the heart's action is sensibly diminished. Sometimes a hot mustard foot-bath will give relief.

The passive congestive variety demands a different mode of treatment. In many cases this variety is found associated with cardiac disease, and most frequently where there is predominant dilatation. Hypertrophy gives rise to the active variety. Improve the condition of the blood by the use of iron, quinine, bitter tonics, alcoholic stimulants, good food, and stimulate the heart's action by the use of the following:

℞. Tinct. digitalis ..... ℥ iii.
Spts. amm. aromat ..... ℥ vi.
Spts. lavand co.,
Syr. simp. ää q. s. ad ..... ℥ iii.
M. Sig. ℥ i. q. 4 h.

Cerebral anæmia produces a headache, which is often mistaken for the passive cerebral congestive form. It is often associated with general anæmia, nervous exhaustion, and may occur in heart disease in consequence of enfeebled heart power, such as is met with in enlargement with dilatation, fatty degeneration, and myocarditis. Improve the general condition of the patient, and stimulate heart's action as recommended in the passive cerebral congestive variety. Nitrite of amyl will relieve the immediate headache. Let the patient inhale three to five drops of it on a piece of cotton, placed within one nostril while the other is held closed. When associated with nervous exhaustion, I employ the following:

℞ Strych. sulph ..... grss.
Tinct. fe. chlor ..... ℥ ij.
Glycerine ..... ℥ ss.
Infus. gentian q. s. ad ..... ℥ vj.
M. Sig. ℥ ss. after meals, in a wineglass of water.

A word as to alcoholic stimulants. These are beneficial in headache dependent on cerebral anæmia. Champagne is a specially favorite form, and is much relished by those who suffer from nervous exhaustion. You should use caution in recommending it to such patients, as it may lead to serious results. Give it always as a remedy and not as a beverage. A safe plan is to recommend brandy, a tablespoonful after each meal, and limit the champagne to one glass, and let it be taken with the dinner.

Cerebral tumors give rise to headache, often severe. In all cases of cerebral tumors, give iodide of potassium; for it cannot be safely said that in any given case the tumor does not depend on syphilis, and by administering the remedy you give the patient the benefit of the doubt.

There is reason to believe, too, that patients with cerebral tumors, dependent on other and unknown causes, are benefited by the use of iodide of potass. I have previously given you directions as to the method of giving the iodide. Sometimes the pain is so severe that you are justified in resorting to opium to relieve it. If there be much sleeplessness, give sleep by the use of the bromide and chloral mixture.

The headache of cerebral softening may be palliated by opium and rest. Such patients should have the best possible hygienic surroundings. If there be sleeplessness and much irritability of the nervous system, the combination of bromide with chloral is indicated. Ergot has been used for the relief of the headache, in these cases, by those having charge of insane asylums, where this condition is frequently met with, and the testimony is in its favor as a valuable remedy. It is usually given in large doses, beginning with ℥ j. of fl. ext. ter in die, and gradually increasing to ℥ ss. ter in die.

Almost all cases of increase of temperature of the body above 103°, are attended with headache. To relieve it reduce the temperature, according to the plan given in a previous lecture; apply cold and evaporating lotions to the head, and keep the patient free from noise and excitement. A full opiate will often relieve such a headache, save the patient much suffering, and effect favorably the progress of the fever.

The mere mention of worms in the alimentary canal, hemorrhoids, uterine and ovarian disturbance, and optical defects, as causes of headache, will suggest the remedy.

DIAGNOSIS OF ANEURISM.

By W. B. DUNNING, M.D.,

PEEKSKILL, N. Y.

In a very interesting and instructive monograph on the Diagnosis of Aneurism, Dr. Stephen Smith remarks "that the symptoms most relied on in the diagnosis of aneurism may be present when there is no aneurism, and may be absent when aneurism exists." * In illustration of this truth I beg to report the two following cases:

I. Aneurism Mistaken for Semi-Malignant Tumor.—A few years ago I was invited, being then house-surgeon to Bellevue Hospital, to see a case of tumor in the popliteal space, which it was proposed to remove. The patient was an Irish laborer, 32 or 33 years of age, who had always had good health until two or three years before, when he first noticed a small growth of the size of a walnut in his left popliteal space. He had never received any injury in this region, had never had syphilis, and knew of no cause which could explain its presence. It had gradually increased in size until the time of my visit. In consequence of its increasing size and its apparent effect on his health and spirits, the patient had been for some months desirous of an operation for its removal. His surgeon, a man of skill and experience, had repeatedly examined the tumor, and, without expressing a positive opinion save that it was not an aneurism, was inclined to regard it as a sarcoma. When I saw the patient he was somewhat emaciated, but on the whole all his functions were in a healthy condition, except that lack of exercise and anxiety might have depressed his spirits and strength. The tumor was then about nine inches in circumference, completely filling the popliteal space, and protruding from it about three inches, spherical, hard and inelastic, non-adherent to the skin, having no pulsation, uninfluenced in size by pressure on the femoral artery, and having no bruit. A piece of paper was laid upon the tumor, but received no perceptible movement from it, thus giv-

* *American Journal of Medical Sciences*, 1853, vol. [illegible], p. [illegible], vol. [illegible], p. 101; and 1874, vol. i., p. 17.

ing additional evidence of the non-existence of pulsation. Neither did the pulsation of the artery below the tumor seem at all diminished. Was it an aneurism? This was the first question suggesting itself to me on seeing the patient, and all the tests indicated above were applied to answer the question. It was a tumor in the course of an artery, but presented no other feature whatever of an aneurism. As an experimentum crucis, a hypodermic needle was inserted, but its withdrawal was followed by no liquid of any kind. Our opinion then was, that it was probably not an aneurism. My friend, who was in charge of the case, was certain that it was not, but my hospital experience had impressed me with the uncertainties in the diagnosis of tumors, and particularly of aneurisms, and I was less confident. He decided to operate at once. The attempt was attended with the most profuse hemorrhage, followed in a few hours by death. The tumor, as examined after death, was found filled with concentric layers of fibrine, occupying its entire space save a small cavity in the course of the artery. This condition of the tumor went far to explain the absence of symptoms. It had no appreciable pulsation nor bruit, because so considerable a mass of fibrine intervened between the artery and the examining finger. It did not diminish in size on pressure of the artery above, because its constituents were almost wholly solid, and this pressure could remove only the liquid portion, and finally an exploratory puncture brought no blood, because the needle penetrated only into the solid fibrine.

II. Fatty Tumor Mistaken for Aneurism.—A lady over eighty years old recently died during my attendance upon her, having presented during the two months preceding her death symptoms, subjective and objective, of mitral insufficiency. She had been for many years a sort of curiosity to the medical men of the neighborhood, on account of an immense tumor on the right side of the neck, which had been regarded by all who had examined her as an aneurism. It had existed over thirty years, and her friends had been repeatedly warned that it might rupture at any time and the patient bleed to death. But she continued to live, the aneurism did not rupture, and she died at a good old age of another disease. At the time of death, this tumor was about thirteen inches in circumference, of an ovoid form, non-adherent to the skin, inelastic, hard to the touch save at one circular spot an inch in diameter, and had presented three features of an aneurism, viz.: (1) a tumor in the course of an artery; (2) an expansive pulsation felt distinctly by the finger placed on any part of the tumor, and (3) a distinct bruit. Pressure on the artery was impracticable as a test; and, as for years there has been no question as to operation, no exploratory puncture was made. I repeatedly examined the tumor during life, and never failed to detect both the pulsation and the bruit. Many other physicians had also examined it, and all agreed, so far as I can learn, in the opinion that it was an aneurism. The post-mortem section showed the falsity of this opinion, presenting an immense fatty tumor, surrounded by layers of calcareous plates.

Looking back on this case, it hardly seems possible that any other opinion could have been formed than was formed. The long duration, indeed, seemed to contra-indicate aneurism, but, on the other hand, how otherwise could be explained the expansive, uniform pulsation, and the bruit?

Small-pox has been fatally prevalent for many weeks in Manchester, Salford, and Liverpool.

Reports of Hospitals.

BELLEVUE HOSPITAL.

Aneurism and Diseases of the Heart.—Notes of Practice and Peculiarities of Treatment.

Thoracic aneurisms—remarkable duration—independent of injury, syphilis, or rheumatism—difficulty in diagnosis.

Three cases were seen which illustrated points of sufficient interest to make them worthy of mention. The chief point of interest in the *first* case was the long duration of the aneurism when considered in connection with the present condition.

The patient was a man, æt. 32 years, and had been admitted to the hospital in 1872. There was a very indistinct history of syphilis in the case; no history of rheumatism, and the man had been temperate. Evidences of thoracic aneurism were found when he was admitted, and at the last examination there was an undoubted aneurismal tumor, about four inches in diameter, situated in line of the ascending portion of the aorta, and projecting to the right and anteriorly. It had made its way through the thoracic walls and was covered only by fibrous tissue and integument. A double murmur and slight fremitus were obtained, and the tumor had both pulsating and expansile movements. There was present also a double aortic murmur; also a mitral direct murmur, and a very faint mitral regurgitant murmur. No particular restriction of the patient has been insisted upon, and yet he was exceedingly comfortable. There was a point with regard to the medicinal treatment in this case which will be mentioned after reference has been made to the other cases. The case was instructive with regard to prognosis.

The *second* case was interesting on account of its long duration, and also the remarkable diminution which had taken place in the size of the tumor. A male patient, æt. 38 years, who gave a syphilitic history, and had suffered from hæmoptysis prior to the evidence of aneurism, was admitted to the hospital the last time in 1873.

In this case, also, the tumor had made its way through the chest wall anteriorly, and the end of the eroded second costal cartilage could be distinctly grasped by the fingers. One peculiarity of the case was that there had never been present any aneurismal murmur; nor were there any cardiac murmurs. In neither of these cases was there any obstruction of the radial pulse. The aneurism in this case had been in existence probably between four and six years, and within the last year and a half had diminished in size nearly one half. In this case, also, no restriction had been insisted upon, and the patient had several times returned to the hospital drunk, when given a leave of absence. Evidences of lung consolidation had developed within a few months, but, notwithstanding that and the aneurism, the man was feeling very well. He also had been receiving the remedy to be mentiond hereafter.

The *third* case was one in which there had been some question with regard to diagnosis, and the history will be given in detail.

A laborer, æt. 42 years, was admitted, and gave the following history: He had had "chills and fever," which was all the sickness he had ever had in his lifetime. He had not had either syphilis or rheumatism. The first thing noticed was a pain in the chest extend-

ing from a point midway between the sternum and nipple, across to and down the under side of the right arm, but when lying upon the back the pain would stop entirely. It was made worse by exercise and a deep inspiration, and there was shortness of breath, but no cough or expectoration. He had suffered somewhat from bleeding piles. That completed the history. The chest being exposed, a pulsation was noticed in the second intercostal space to the right of the sternum; pulsations were seen in both carotids, in both subclavian arteries, most marked upon the left side; a diffused pulsation around the apex; a pulsation in the epigastrium; but at no point in the chest wall was bulging or retraction apparent. Upon palpation a purring thrill was felt over the apex; an impulse under the clavicle in both sides, and a slight impulse at the point where the pain first commenced. The apex-beat was carried downward and farther to the left than normal. Upon percussion an increased area of dulness was found over the ascending portion of the arch of the aorta, and to the right, and cardiac dulness extended two inches to the left of the nipple.

Upon auscultation, a murmur, having its maximum intensity over the apex, preceded the first sound of the heart; another murmur, synchronous with the second sound of the heart, was heard with its greatest intensity at the base; also a double murmur over the left carotid, besides a peculiar pulling murmur over the area of dulness to the right of the sternum, which was synchronous with the cardiac impulse, but absent when the patient was in the horizontal position, and sounded more like forcing air out of lung tissue than a real aneurismal *bruit*. The respiratory murmur was less distinct upon the right than upon the left side of the sternum, but the absence of bronchial breathing excluded lung consolidation. There was only slight diminution in the intensity of the respiratory murmur in the neighborhood of the area of dulness at the right of the sternum. Pulsation in the right radial artery was less distinct than in the left.

The case was interesting for two good reasons:

1. It illustrated how extensive cardiac disease might become independent of injury, syphilis, or rheumatism.

2. It illustrated the difficulty in making a diagnosis in certain cases, and also showed how easily the real difficulty might be overlooked, for the patient had already been treated for pleurisy and neuralgia, but in neither instance had a physical examination of the chest been made. The case has been placed in this group not because the symptoms were positively diagnostic, but rather because they were strongly suggestive, and is thus turned over to the reader for study.

Now, with regard to treatment, all three cases had received the iodide of potassium in large doses, and in all a marked improvement had been manifested. But there was one thing to be thought of while estimating the effects apparently produced by the drug, namely, that *rest* had been enjoined, although no special restriction had been insisted upon, such as lying in bed; and the question naturally arose: was it the *rest* or the *drug* that afforded the relief?

ACUTE BRIGHT'S DISEASE—SIALAGOGUE EFFECT OF JABORANDI.

The case presented certain peculiarities which made it worthy of note. When admitted, only 7½ to 11½ ounces of urine were passed in twenty-four hours, and it contained albumen, epithelial and granular casts. The patient was dry-cupped over the kidneys; received a cathartic, composed of croton oil, podophyllin, and elaterium, and dram doses of the fluid extract of jaborandi. The latter was administered for the purpose of producing diaphoresis, and soon after the second dose was given the patient broke out in exceedingly profuse perspiration, and, in addition, the remedy acted as a sialagogue to such a degree that ℥ xxii. of saliva were collected in four hours. At the time of our visit the patient was passing ℥ lx. of urine in twenty-four hours, acid, had a sp. gr. of 1023, and contained no albumen. After the operation of the cathartic, the infusion of digitalis with acetate of potash was administered.

THE SIALAGOGUE EFFECT OF JABORANDI PREVENTED BY HYPODERMIC INJECTIONS OF MORPHIA AND ATROPIA.

When jaborandi is to be administered it has been customary to precede it with a hypodermic injection, consisting of ½ of a grain of the sulphate of morphia, and $\frac{1}{67}$ of a grain of the sulphate of atropia. This has been done for the purpose of preventing salivation, and has proved successful.

ACUTE ARTICULAR RHEUMATISM TREATED WITH SALICYLIC ACID.

A number of cases had been treated by administering six grains of the acid every two hours, and continuing it in from six to ten grain doses three times a day, as the acute symptoms subsided. In every instance the symptoms had been markedly relieved, and, as a rule, quite promptly. This plan was adopted independent of the use of alkalies.

BRONCHOCELE—TREATMENT BY INJECTIONS OF ALCOHOL.

A male patient, æt. 28, native of Delaware Co., N. Y., first noticed that his neck was enlarged twelve years ago, and the enlargement had been generally increasing since. The goitre was enormous, and most marked upon the right side.

The case was to be treated by hypodermic injections of about twenty drops of alcohol, repeated according to effect produced. The injections were used with the idea of producing shrinking, as the result of the formation of new connective tissue in the enlarged organ.

POTT'S DISEASE—PARAPLEGIA.

The disease commenced in this case about twenty-three years ago. There was no paralysis when the bone disease was first developed, and probably the healing process was almost completed when the paraplegia first appeared. The first attack of paraplegia occurred in 1857, lasted sixteen months, and involved both motion and sensation. He laid upon his back all the time, being entirely unable to stand or use the legs. Complete recovery took place.

The *second* attack occurred about the year 1872, and lasted about two months. In that attack motion only was involved; again recovery was also complete.

The *third* attack of paraplegia occurred only a short time since; was of brief duration; involved motion only, and was followed by a complete recovery.

How were these attacks to be explained?

The *first* was believed to be due to the pressure from the deformity itself giving rise to an obstruction in the circulation, or pressure from an accumulation of inflammatory products.

The *second* and *third* attacks were thought to be due to some reflex condition, or perhaps due to some circulatory disturbance. The ready manner in which recovery took place seemed to place them beyond being due to pressure.

INFLUENCE OF PREGNANCY UPON THE UNION OF FRACTURED BONES.

A female patient had sustained a fracture of the lower end of the radius about two months previous to her confinement, but union had not taken place when the child was born. She went on and nursed her baby; but union not taking place, as was expected after confinement, the child was weaned, and the bones united within a very short time.

Two other cases were noted in which fractures had occurred during pregnancy, and in which union did not take place. On the other hand, a woman who had been pregnant about two months was brought into the hospital because of a compound fracture of the femur. It was thought by some of the visiting surgeons that amputation was necessary, but the patient refused, and the limb was dressed by means of the ordinary extension and counter-extension apparatus known as Buck's extension apparatus. Miscarriage threatened for twenty-four hours, but did not occur, and good union of the bone took place. The patient being rather uneasy and quite troublesome, got up after union had occurred, and in some of her perambulations fell and fractured the same femur the second time at about the same place where the first fracture occurred. The fracture was reduced, and when we saw her, union had again taken place.

HYSTERICAL HIP-JOINT DISEASE.

The patient was a girl about sixteen years old, and had been sick three years. She said she received an injury from a fall, and that then the trouble about her hip began. The position of the limb was such as seen in the second stage of morbus coxarius, but when an examination was made with reference to that disease, not a single symptom was present except the obliteration of the gluteo-femoral crease. Besides, the limb affected was larger than the well one. The visiting surgeon regarded it as a case of hysterical hip-joint disease, for the girl was exceedingly nervous, and at the same time he gave a very unfavorable prognosis as regarded the ultimate usefulness of the limb. For, as far as his experience had enabled him to judge, the peculiar condition which prompted or compelled or induced such patients to simulate deformities could not be easily, if ever, overcome.

HOW TO DECIDE THE QUESTION OF OPERATION IN A CASE OF PERI-TYPHLITIS.

The case was one in which well-marked symptoms of peri-typhlitis had been developed, and a hard mass extending from low down in the iliac fossa to above the crest of the ilium could be distinctly mapped out by palpation and percussion. Tenderness was very well developed upon pressure over the same region, and there was arrest of respiratory motion below the umbilicus. Pulse 110, and temperature 101½° F. The patient received a moderate amount of opium, was kept perfectly quiet in bed, and had local applications of light warm poultices. At the time of our visit he had been in the hospital three days, and had been sick a week before his admission. On the seventeenth day of his sickness there was less pain, the tumor had diminished in size, and it was quite evident that resolution was taking place. That fact led the visiting physician to remark that he had seen several cases of peri-typhlitis which had progressed until it had seemed that suppuration was inevitable, and yet from that point a change for the better had occurred, and resolution had taken place. He regarded it as a matter of great difficulty, in many of these cases at least, to determine the exact time when pus had been formed, and in no case, therefore, would he consent to any surgical operation for the evacuation of an abscess in that region until pus had been detected by means of the aspirator. Under such circumstances the aspirator was regarded as an instrument that could render signal service, and when pus could be reached by the use of the needle, then, and not until then, should recourse be had to any surgical operation of greater severity. In the case before us a good recovery took place.

Progress of Medical Science.

REPORT OF FORTY-ONE CASES OF ANTHRAX.—Dr. Dobrzycki has met with forty-one cases of anthrax within a period of four years; thirty-six of these cases occurred during an epidemic, and the remaining five were sporadic. In most of the cases the patients had been employed about infected animals, while in some cases the flesh of these animals had been eaten. Dr. D. divides cases of anthrax into two classes: those which are produced by direct inoculation, and those through the medium of the stomach or lungs. In the former class the disease appears as a malignant pustule when the inoculation takes place on the extremities, and as a carbuncle or anthrax malignus when it takes place on the head or trunk. In the second class the disease either runs its course without local lesions, or a consecutive anthrax malignus develops. Of course the lines of distinction between the different varieties are not always sharply marked.

In these 41 cases, there were in 17 cases only, a malignant pustule, in 12 cases a primary anthrax malignus, in 8 cases a consecutive anthrax malignus, in 3 cases pustula maligna and primary carbuncle both, and 1 case ran its course entirely without local symptoms. Only six of the 41 patients died; this very favorable result being ascribed to the energetic treatment adopted in every case. All suspicious spots on the body were at once cauterized with caustic potash or the red-hot iron, the latter being the surer method; the wounds were then dressed with carbolic acid. Internally rather large doses of carbolic acid were administered, about a drachm being given in the course of twenty-four hours.

Dr. D. believes that it is dangerous to eat the flesh of diseased animals; where this has been done with impunity, he thinks it was because the flesh was taken from parts at a distance from the point of infection. —*Allgemeine Med. Central-Ztg.*, May 17th, 1876.

A CASE OF MYOSITIS OSSIFICANS.—Dr. Huth reports a well-marked case of this very rare disease. It began as a small "hardness" under the chin of a boy 20 months old. Gradually the muscles of the neck, trunk and extremities became stiff and ossified, and now the patient, who is 4½ years old, presents the following lesions: There is a small exostosis on the left parietal bone. The masseter muscles are hardened in spots; in the muscles of the neck some fasciculi are ossified in the shape of ropes or rosaries. The muscles of the thorax form a sort of bony coat of mail. On the back there are five or six exostoses the size of walnuts. The musculi lumbales are hardened on both sides; in the abdominal muscles a bony string, as thick as a finger, extends from the edge of the ribs on the right side to the pubes, while on the left side there are only a few hard nodules. Both shoulder-joints

are perfectly stiff, and the arms lie close against the trunk, but the forearms are healthy and movable. The muscles of the left hip and thigh are hard and stiff; but those of the right hip and leg are unaffected. The left thigh is fixed at a right angle to the trunk, and the left leg at a right angle to the thigh, although a little passive movement can be given to the knee-joint. The child is bound securely in a low chair, and by means of the right leg he can move himself around from one part of the room to another. With the help of a long fork he can feed himself with solid food, but all fluids must be given to him by others. It remains only to mention that no cause can be found for this affection, and that no treatment seems to be of any avail.—*Allg. Med. Central-Zeitung*, May 20th, 1876.

THE PREVENTION OF PYÆMIA IN HOSPITAL PRACTICE.—An instructive paper on this subject was recently read before the Norwich Medico-Chirurgical Society, by Mr. Cadge. It is hard to tell how prevalent pyæmia really is, for it is only in a few hospitals that accurate records are kept or reports made. In four of the London hospitals, of the deaths after major amputations, no fewer than 37.8 per cent. (!) were caused by pyæmia. Mr. Bryant tells us that forty-two per cent. of the deaths at Guy's Hospital were due to it, and Mr. Callender reports that for ten years at St. Bartholomew's Hospital it caused thirty-nine per cent. of the deaths following amputations for disease. In the Norfolk and Norwich Hospital, during the last five years, there have been thirty-two deaths from pyæmia.

Of late years, however, pyæmia has been effectually checked, and almost entirely prevented in several hospitals, and Mr. Cadge alludes to three, to show that the same object has been obtained by different methods. Prof. Lister's wards in the Glasgow and Edinburgh infirmaries, "from being about the most unhealthy in the kingdom, were converted into models of healthiness" by means of the antiseptic treatment of wounds. In the six years during which he has been surgeon to the Edinburgh Infirmary, he has had only one case of pyæmia, although his wards were dirty and overcrowded by bad cases. Saxtorph, of Copenhagen, Nussbaum, of Munich, Thiersch, of Leipsic, Volkmann, of Halle, Bardeleben and Langenbeck, of Berlin, and Von Busch, of Bonn, state emphatically that pyæmia and other septic diseases, which had previously been disastrously common in their large hospitals, have almost entirely ceased since the introduction of the antiseptic treatment.

During the five years that Mr. Callender has been attached to St. Bartholomew's Hospital, all his cases of compound fracture, sixty-six in number, recovered; of forty-nine amputations, only three died; and out of 405 operations done in the theatre, there were but three cases of blood-poisoning, and these he attributed to faulty management. These results, which are astonishing when compared with the results of the preceding ten years, were obtained by exceeding care in attending to hygienic surroundings, to the observance of strict rest, and to the absolute cleanliness of wounds; to the use of drainage tubes, and of carbolic acid dressings.

Lastly, in the Norfolk and Norwich Hospital during the year ending April 1st, 1876, there were 350 operations and wounds, but *not one* death from pyæmia or traumatic erysipelas, while during the preceding five years, pyæmia had caused thirty two deaths. This favorable change was brought about by the avoidance of over-crowding, great attention to ventilation, treating the more important operations and severe injuries in a separate building, but especially by great attention to cleanliness of the wards, bed-linen, bandages, etc., etc., and to all the details of nursing. The treatment of wounds has chiefly consisted in the free use of drainage tubes, and the application of carbolized oil on lint covered by cotton-wool, and the occasional use of the full antiseptic method. The great difficulty in carrying out this plan, is in getting the requisite number of trained nurses, and nursing superintendents.

Mr. Cadge suggests increasing the cubic space allowed to each bed to 2,000 or 2,500 cubic feet, and isolating as far as possible, all cases of severe operations or serious accidents, in single rooms, as further calculated to diminish the risk of pyæmia. He also recommends the appointment of governmental visiting boards with full powers, and that every hospital should be obliged to publish full yearly reports, with both of which suggestions the Editor of the *British Medical Journal* heartily agrees.—*British Medical Journal*, April 22d, 1876.

CARBOLIZED CATGUT IN LIVING TISSUES.—Mr. Fleming, of Glasgow, has recently performed a number of very interesting experiments in that city, with the object of ascertaining what becomes of carbolized catgut when introduced into living tissues. At first he simply inserted carbolized catgut with a needle beneath the skin of a dog's back, putting fresh pieces in new places at definite intervals of time. At the end of a month the dog was killed, and no traces of any of the pieces could be found, except in two places where abscesses, probably due to the use of a dirty needle, had formed around pieces that had only been in a few days. In his next experiments, in order to mark the position of the catgut, he twisted a bit of fine silver wire about it, but the wire prevented the cutting of thin sections. He then substituted for the wire carbolized silk, which can be closely applied to the catgut, is little altered in the tissues, seems to set up no irritation, and can easily be cut with the razor. With this he performed about twenty experiments on dogs and rabbits, in the latest experiments the animals being killed by bleeding and a two per cent. solution of Brücke's soluble Prussian blue injected into the abdominal aorta. He then cut out the pieces of catgut with some of the tissues in which they were imbedded, froze them, or hardened them in spirit, and made sections in the usual way.

Microscopical examination showed that a gradual softening takes place from without, in the catgut breaking down and becoming infiltrated with cells, probably leucocytes. This part of the process takes from five to twenty days, varying with the specimen of catgut, the tissue in which it is situated, and the age and vitality of the animal. Next, the pultaceous mass into which it has been converted is permeated with blood channels, and ultimately may be described as a cast of the catgut in a kind of granulation tissue freely supplied with blood-vessels, which in many of the specimens were very fully injected.

By the aid of these observations we can easily account for the different results obtained by the use of catgut in different hands. We see that it is in reality merely a temporary ligature, because in the softening stage it cannot be said to have any constricting effect. Whether this temporary constriction lasts long enough to produce embolic occlusion of the vessels, depends upon the sample of catgut and the vitality of the patient.—*The Lancet*, May 27th, 1876.

PELLAGRA, ITS CAUSES AND NATURE.—Dr. Winternitz, of Vienna, contributes to the *Vierteljahrsschrift*

für Dermatologie und Syphilis, an exhaustive paper on pellagra, a disease which is supposed to be confined to parts of Italy, France, and Spain, and about whose history and nature much uncertainty exists. He analyses the accounts of the disease given by Italian and French writers, and concludes that several very different and distinct diseases have been described and treated under the name of pellagra. He thinks that cases of pellagra will be less and less frequently reported, in proportion to the increase of our knowledge and skill in diagnosis. The results of treatment also show that different diseases have been classed as pellagra, mostly the diseases generated by want and misery. The so-called pellagra is characteristically a disease of the first months of the year, which is the very time when the poor suffer most from cold, uncleanliness, and want. The provisions laid in for the winter are by that time consumed, and the stomach, loaded with indigestible substances, ceases to perform its work. At the same time various eruptions of the skin result from the long-continued want of ablutions. The author closes his paper with the following conclusions:

1. Numerous diseases of the skin, bowels, and mind, and also diseases characterized by a retrogressive metamorphosis, such as scorbutus and tuberculosis, prevail everywhere where pellegra is said to be found.

2. These diseases present no local peculiarities.

3. They are excited by the same causes, and follow the same course, as in other localities, and consequently it is unnecessary to seek for any specific causes for them.

4. These different diseases have no special connection with one another, but, as in all other localities, may present numerous combinations.

5. They occur in lunatic asylums, which, until recently at any rate, did not present the best hygienic conditions.

6. In these asylums they even occur more frequently than elsewhere, which is not surprising when we consider the uncleanliness and the unhealthy food of most lunatics.

7. His experience in the Lunatic Asylum at Venice convinced him that accidental diseases of the skin and abdominal organs as often preceded as followed the insanity, and that these complications resulted only from individual conditions.

8. As a rule the cases classed as pellegra consisted of the diseases consequent on want and misery, the universally prevalent "Mali della miseria."

9. Consequently pellagra as an independent, specific disease, confined to circumscribed areas, does not exist.

10. The pathological history of *raphania maiztica*, as an independent disease, has yet to be written; it has at all events no connection with pellagra.—*Vierteljahresschrift für Dermatologie und Syphilis*, 2 Heft, 1876.

Treatment of Placenta Prævia.—In a paper on this subject, published in the *American Practitioner* for June, Dr. Parvin, of Indianapolis, advises, in conformity with the teachings of Greenhalgh and Thomas, the induction of premature labor, and expresses a belief that the mortality of both mothers and children, in cases of placenta prævia, will undergo a marked diminution when this is adopted by the profession as a rule of practice. He considers Barnes' dilators to be the safest and best means for the induction of the premature labor, and they moreover bring it on more rapidly than any other means. The vaginal tampon is difficult of application; is uncomfortable to the mother; does not remove the possibility of a dangerous internal loss of blood, and possibly may lead to a separation of the placenta and death of the child. Ergot is objectionable, except when the os is well dilated or dilatable and the labor can be speedily terminated, for the tetanic contractions it excites are apt to asphyxiate the child. Puncture of the membranes is obviously dangerous for the child, and as far as the mother is concerned is not free from danger, as it may possibly change an open into a concealed hemorrhage. Podalic version increases the risks to the child's life, and probably may be limited almost if not quite altogether to cases of shoulder presentation. Complete separation of the placenta, as advised by Sir James Simpson, is a method which ignores the child's interests, and has never received any general professional support. Finally the partial detachment urged by Dr. Barnes does not seem to be a rational mode of treatment, for it simply increases the bleeding surface.

New Treatment for Tricophyton.—At the meeting of the *Société Médicale des Hôpitaux*, on May 26th, M. Laillier read, in the name of M. Lespian, a paper on the treatment of parasitic and non-parasitic affections of the skin. In 1875, while stationed in the Pyrenees, M. Lespian saw a number of dogs that were suffering from a parasitic affection that bore considerable resemblance to tinea: scaly cutaneous eruptions, the hairs glued together and breaking off close to the roots, and slaty color of the skin. His own two dogs were affected, and on microscopical examination he found almost always spores. Within a short period, thirty-four persons, twenty-eight children and six adults, were affected with the same disease, the parts affected being those that are most frequently in contact with the hands. The treatment employed by M. Lespian consisted in painting with the following mixture: R. Tannin, grs. xv.; tincture iodine, ʒ iiss.; glycerine, ʒ v. M. When the disease was not very extensive, two applications daily for four days generally produced a cure. Pre-existing crusts were softened by the application for twenty-four hours of wads of cotton wadding or charpie soaked in olive oil or glycerine. M. Lespian has sometimes seen fever, ptyalism, and laryngismus occur during the treatment, which probably resulted from iodism.—*La France Médicale*, May 31st, 1876.

Incontinence of Urine.—Mr. Brenchley writes to the *Practitioner* that he has seldom seen much good done in the above disease by belladonna, iron, or bromide of potassium, but has met with much success with the following combination of ergot and iron:

R. Tinct. ergotæ..... ....℥ x.
Tinct. ferri. perchloridi.....℥ v
Spt. chloroformi.....℥ v.
Infus. quassiæ.....ad ʒ i. ter die sumend.

Esmarch's Bandage for Chronic Ulcers.—Dr. Turney, of Ohio, has employed this bandage in seven cases of ulcers of the leg, one a typical indolent ulcer, with indurated edges, over the internal malleolus of a woman over eighty-five years of age. In six cases the cure was rapid and permanent; in one a portion of the cicatrix gave way, but it was again progressing favorably when the patient disappeared. The bandage was applied firmly from the foot to the knee, once a day, and allowed to remain as long as it could be borne, about ten or fifteen minutes. No other treatment was employed. With each application oxygenated blood takes the place of a fluid unfit for nutrition; the strong pressure effectually overcomes the passive congestion and œdematous infiltration, and the distended vessels, completely relieved of their load of vitiated blood, have an opportunity to recover their lost tonicity.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, August 5, 1876.

COTTAGE HOSPITALS.

Mr. James W. Beekman, one of the Governors of the New York Hospital, and chairman of a committee to report on the practicability of founding a village of cottage hospitals, has presented a very elaborate contribution* to the subject, which deserves the thoughtful consideration and careful study of every one interested in hospital construction.

In our recent articles upon hospital construction and organization, we took occasion to urge the establishment of cottage hospitals; and it is with a feeling of congratulation that we can add the influence of this distinguished gentleman to the advocacy of the principles involved. A careful examination of the subject in all its varied aspects, has caused him to arrive at conclusions which commend themselves with the force of conviction to every candid observer.

He commences his report with the following startling, yet truthful, statement:

"That in all the hospitals whose records have been preserved, it is found that, although the art of surgery has made great progress, no improvement in the cure of patients has been attained—the average mortality after operations remaining unchanged for thirty or forty years; and that in small and separate hospitals the mortality diminishes with the size of the building. In the treatment of disease the same rule holds true; the nearer the condition of the patient approaches that of a member of a well-ordered household, the better are the chances of his recovery. The most successful hospital, therefore, will be a cottage; and the best general infirmary will be a village of such cottages, surrounded by gardens and not bare of trees. Pure air is the first necessity. Great cities have been supposed to require great hospitals in their midst, so as to receive the large number of sick and maimed persons who seemed likely to require instant relief. In fact, however, it turns out that the patients who are produced by a great city are wonderfully few."

Taken in connection with the fact that the Board of Governors have nearly completed a costly edifice, for hospital purposes, several stories high, in the heart of the city, and on the verge of what was once a swamp, the remarks have a bearing which is at once important and significant.

Appreciating the fact that this statement might be the subject of much criticism on the part of those who from prudential and conscientious motives, might be disinclined to believe it, Mr. Beekman has fortified it with an array of facts which are hardly open to question.

The statistics of Dr. Farr, the Registrar-General of England, are presented, to show that "the mortality of the sick who are treated in large general hospitals of populous towns is twice as great as the mortality of the sick who are treated in small hospitals in small towns." The remarkable statements of Mr. Erichsen, Prof. Tyndall, and the late Dr. Parkes, are also given to show the influence which the so-called "disease dust" accumulating in these large charities has in producing pyæmia, erysipelas, puerperal fever, and other hospital diseases. The experiences of the Lincoln County, and Norwich and Norfolk Hospitals are also quoted, showing how impossible it is to eradicate disease germs when the circumstances of long saturation has given them a home within the walls.

The most remarkable and interesting part of the report is that which gives the comparative mortality of cases treated in large hospitals, and those cared for outside, either in the homes of the patients or in small rural establishments. By comparing the death rate of dispensary practice with that of the mortality of hospital patients, he concludes that the latter is two and a half times greater than the former—a fact which can hardly be explained on the score of better accommodations than are to be found in well-regulated institutions. That the number of beds in a given hospital has much to do with the increase of mortality, Mr. Beekman presents the following table, for the correctness of which he vouches:

	PERCENTAGE OF DEATH RATE.
In British hospitals with 300 to 600 beds,	41 in 100 die.
" " with 300 to 201 "	30 " "
" " with 200 to 101 "	23 " "
" " with 100 to 26 "	18 " "
" " with 25 beds or less	14 " "
In isolated rooms in country practice	11 " "

Bearing upon the same question, he quotes the following from Sir J. Y. Simpson's work on Hospitalism:

SIZE OF HOSPITAL.	DEATH RATE.	PER CENT.
1st Series.—In large and metropolitan British hospitals, containing from 300 to 500 beds or upwards, out of 2,089 limb amputations		
855 died, ...	or 1 in 2.4	41
2d Series.—In provincial hospitals, containing from 201 to 300 beds, out of 803 limb amputations		
228 died	or 1 in 3.5	29

* Report of the Committee on a Village of Cottage Hospitals made to the Governors of the Society of the New York Hospital, 1876.

SIZE OF HOSPITAL.	DEATH RATE.	PER CENT.
3d Series.—In provincial hospitals, containing from 101 to 200 beds, out of 1,370 limb amputations 301 died.....or 1 in	4.4	23
4th Series.—In provincial hospitals, containing from 26 to 100 beds, out of 761 limb amputations 134 died.....or 1 in	5.6	18
5th Series.—In provincial hospitals, containing 25 beds or under, out of 143 limb amputations 20 died.....or 1 in	7.1	14
6th Series.—In British private country practice, where the patients operated on lay in single or isolated rooms, out of 2,098 limb amputations 226 died.....or 1 in	9.2	11

It is well known that the arrangements of our general hospitals, during the last war, carrying out as they did the cottage plan, gave a low rate of mortality, which was a matter of astonishment to every one.

Mr. Beckman's report, being, for the most part, statistical in character, does not admit of a very detailed presentation on such anoccasion as this; but we believe we have given enough to show the nature and drift of his argument in favor of cottage hospitals, and to appreciate the force of his conclusions.

Believing as he does, in common with many others, that a collection of cottages in the country is the surest means of decreasing the mortality in hospitals, he recommends a plan which is calculated to meet the end in view. It is, in brief, that cottages should be erected out of town, within convenient access to it by rail or steamboat. Although the idea is somewhat Utopian, the difficulties in the way of the accomplishment of the design are not insurmountable. The arguments in favor of large hospitals, are convenience of administration and accessibility, but these are counterbalanced by decrease in mortality, by the present facilities of transportation, and by the comparative cheapness of smaller establishments. In a large city like New York, a few miles out of town by rail or steamboat would not involve more time in travel than would be consumed in the ordinary trips made by the horse-car. To the patient the dangers of transportation would not be so great, jolted over cobble stones for miles, as in an easy ambulance car or river transport.

In regard to the question of economy, Mr. Beckman very significantly suggests:

"That in this case duty and profit go together. The cheapest way is the best in all ways. We need cheap—not large—buildings, ample space of ground, with abundance of pure drinking water, and some trees. The difference between the capital sum which would be "fixed" and absorbed in constructing a large infirmary in town, and the amount of money which would suffice to pay for and equip a village of cottage wards in the country, will support generously out of its income, when invested, a large number of free-beds."

While we believe the cottage plan of hospital arrangement, as suggested by Mr. Beckman, would be the best, we cannot afford to do without smaller reception houses in different parts of the city. These also could be maintained at small expense, and could be, from time to time, changed as circumstances demanded. As we have always been in favor of having the cottage plan thoroughly tried, we cannot but hope that the wealthy Society of the New York Hospital will heed the suggestions of the writer of the report, and give them the practical turn which is so desirable.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, June 14, 1876.

Dr. C. K. Briddon in the Chair.

TUMOR OF INTESTINE—BRIGHT'S KIDNEY, ETC.

Dr. John H. Hinton presented specimens consisting of the kidneys, with portion of intestine and omentum attached, which had been removed from the body of a man aged sixty-one years. The point of interest connected with these was the singular absence of symptoms during life pointing to the existence of the grave renal disease which was the immediate cause of death. The patient, although not robust, enjoyed a reasonable amount of health, and was able to attend to his business as a financier until three weeks before his death. At that time he first began to complain of the effects of constipation, although he had been suffering from this latter condition during the greater part of last winter. When Dr. Hinton first saw him his attention was called to a tumor in the right iliac region. This was about the size of the fist, midway between the anterior spinous process of the ilium and the umbilicus; was quite firm in consistence, irregular and nodular in outline, and freely movable. The dullness on percussion over this tumor was quite marked, and was in striking contrast to the tympanitic résonance above, occasioned by the accumulation of gas in the large intestine. This latter fact, together with the existence of the tumor in that locality, and the obstinate constipation, gave rise to the suspicion of an organic lesion of the colon. The character of this growth was only surmised. The only prominent subjective symptoms were nausea and pain at the seat of the tumor, colicky in character, and evidently due to the imprisonment of flatus. These distressing symptoms continued, and were only mitigated by opiate injections. There was no change in his symptoms until thirty-six hours before death, when suppression of urine occurred, with slight uræmic symptoms. The uræmia was not by any means well pronounced, the patient being perfectly rational until within three hours of his death. With the suppression there was a coincident cessation of nausea, apparently due to the anodyne effect of the uræmia. The suppression was almost complete, only six ounces of urine being drawn from the bladder during the last thirty-six hours. Death occurred quietly, without coma, and was due apparently more to the exhaustion than to the more direct influence of the

kidney trouble. The advent of uræmia created the first suspicion of kidney disease, and it was not until then that the urine was examined. It was found albuminous, but not markedly so.

The autopsy was made ten hours after death. On opening the abdomen there was no general peritonitis, but local peritonitis was found at the site of the tumor. These adhesions existed between the omentum and intestines, at the ileo-cæcal junction, and extended, although in a slight degree, to the peritoneum of the iliac fossa. The tumor itself was, as previously stated, about the size of the fist, and consisted of a deposit in the substance of the intestinal walls of the ileum, the mucous membrane being but slightly involved; there being but one or two small points of ulceration on the surface of the latter, with limited softening of the submucous tissue. Two and a half inches of the circumference of the ileum were involved, producing a stricture capable of admitting merely the tip of the little finger, and presenting the appearance of an intestinal sphincter at that point. The growth was eccentric rather than concentric. The mesenteric glands were enlarged and infiltrated, and there were also nodules in the omentum. The kidneys showed evidences of old croupous nephritis, with the attendant surface depressions.

At the time of presentation there had been no microscopical examination of the tumor, although from its gross appearances it was evidently cancerous in character.

RHINOPLASTY—PAPILLARY EPITHELIOMA.

Dr. Briddon presented photographic representations of an operation for rhinoplasty at the Presbyterian Hospital, accompanied with the following history by Dr. W. E. Forrest, of the House Staff:

Edward Mauer, aged 33, baker, admitted April 27, 1876. The patient entered the hospital with a tumor on the nose. This commenced as a small pimple four months ago, while the patient was convalescing from a severe attack of variola. It has grown quite rapidly, without pain, and at present is nearly one inch and a quarter in diameter. The tumor is a flattened, circular growth, with elevated edges and a rough papillary surface, presenting all the external appearances of an epithelioma.

The tumor extends from near the root of the nose half way to the tip, covering the dorsum; more of it lying on the left side than on the right side of the nose. Operated on April 28th.

The patient was put under ether, and four incisions made through the sound integument, a quarter of an inch from the edge of the tumor, so as to enclose the tumor in a quadrangular-shaped flap. This piece was carefully dissected off, leaving an exposed surface extending transversely across the nose to its junction with the face, and extending along the dorsum two-thirds of the way to the tip. Then a flap, previously marked out, was dissected from the forehead. This flap extended obliquely upwards and towards the left, was two and a quarter inches in length by two inches in breadth at its upper end, and was left attached by a pedicle to the forehead at the inner end of the right eyebrow. An hour afterwards, when all hemorrhage had ceased, the flap was brought down and stitched into the space from which the tumor had been removed. The lips of the wound on the forehead were approximated by pins and adhesive strips.

April 29.—The patient lost considerable blood during the operation, and did not recover very well from the ether. The circulation in the flap is good and the swelling moderate.

April 30.—The sutures were removed and the flap found to have united throughout most of its extent by first intention. The face is somewhat swollen and has an erysipelatous blush.

May 1. The whole face is much swollen, the eyes closed, and the swelling extending downwards. There is some discharge from beneath the flap, and a very small portion of the lower right corner of the flap has sloughed; the rest is warm. Temperature 104°, pulse 130. The patient was promptly removed to the pavilion, and put upon the treatment for erysipelas.

May 6.—The patient has nearly recovered from the attack of erysipelas. The flap has maintained its vitality and its adhesions. The wound on the forehead is filling by granulation.

May 25.—The patient has returned to the hospital after a two weeks' visit at his home. The flap is healthy and has grown quite large and thick. To-day the pedicle attaching it to the forehead was cut, and an elliptical piece from the side of the new portion removed so as to reduce its size. The edges were brought together with horse hair sutures. On pricking the flap the sensation was referred both to the forehead and to the nose.

After which the Society went into Executive Session.

Correspondence.

INCISION OF THE CERVIX UTERI FOR THE CURE OF DYSMENORRHŒA.

To The Editor of the Medical Record.

Sir:—In your report of the stated meeting of the New York Academy of Medicine for June 1, 1876, I find a pretty full abstract of a paper read by Dr. E. R. Peaslee, some of the statements of which will scarcely be accepted without criticism by practical gynæcologists. While, theoretically, Dr. Peaslee's paper may be regarded as an excellent analysis of the literature of operations for dysmenorrhœa, it seems to me to be misleading as to the feasibility of the operations from which he dissents, and hence of very little value to the practitioner, who must submit his theories to the test of facts. One fact in physiology is worth pages of ratiocination; and it so often happens that our cleverest theories break down in the presence of a test case, that I, for one, in growing gray with the problems of practical surgery, have also grown wary of expressing opinions based upon review of medical literature. In my own operations for dysmenorrhœa, whether proceeding from anteflexion or from stenosis, or both, hemorrhage is about the last thing to give any serious trouble, and conception subsequent to the operation is as frequent as the average among women who have never submitted to the knife; so that I should be wanting in frankness, and in regard for real progress in surgery, if I should neglect to say that I consider Dr. Peaslee's objections to be, in the main, purely speculative, and hence, although ably argued, very unreliable as guides to the practitioner. I have, for instance, generally found the womb resuming its natural position after incision of the cervix, without special manipulation. It is, as I have observed further on, from the case-books of practical surgeons that a true science of surgery is to be constructed. There is nothing so dangerous as a knife in the hands of a blunderer, even in the simplest operation; and nothing safer, even in the most complex operation, than the

same instrument in the hands of a real surgeon, guided by judgment and mature experience. The difficulty is, that your inveterate theorist is rarely dexterous and experienced of hand, and finds his proper function as a professor rather than a practitioner. With these preliminary observations, I will proceed to my own record of cases.

H. K. W. Dysmenorrhœa and sterility. Operated by incision of the cervix posteriorly up to the vaginal junction, and three incisions, one central anterior, and two lateral oblique, each one-eighth of an inch in depth, through the os internum. Used a modification of Civiale's urethrotome, by means of which the depth of the incision can be gauged accurately. The general result was, of course, to convert the anteflexed cervix into a straight canal, longitudinally continuing the body of the womb. Introduced a straight section of laminaria, and retained it in position for five days by packing below it with cotton. The incision healed kindly. Has not since been pregnant.

Mrs. S. J. S. Operated in the same manner as before for dysmenorrhœa and sterility. Patient has not since been pregnant, although the dysmenorrhœa was cured.

Mrs. H. Dysmenorrhœa and sterility. Operated in the same manner. Has since been pregnant and safely delivered at full time.

Mrs. V. Dysmenorrhœa and anteversion. Operated with Simpson's uterotome. Dysmenorrhœa cured. Not pregnant since the operation was performed.

Mrs. G. Anteflexion and sterility. Operated with Simpson's instrument. Dysmenorrhœa cured. Patient left the city soon after the operation was performed, and I have no means of knowing whether she has since been pregnant.

Mrs. W. Anteflexion and dysmenorrhœa. Operated with Simpson's instrument, with perfectly satisfactory results. Present residence of the patient unknown to me, and cannot, therefore, state whether she has since been pregnant.

Mrs. G. Amputated the whole cervix. Hemorrhage was not troublesome. Patient became pregnant a few months after the operation, and was safely delivered after the full period of gestation.

Mrs. M., of Yonkers, N. Y. Anteflexion, dysmenorrhœa, sterility. Incision of cervix with Simpson's instrument. No hemorrhage. Dysmenorrhœa cured.

Mrs. H., widow. Dysmenorrhœa. Same operation. No serious hemorrhage.

Mrs. B. Dysmenorrhœa from anteflexion. Operated by incision with Simpson's curved uterotome. Cured.

Mrs. H. Dysmenorrhœa and sterility from anteflexion. Operated with Simpson's instrument, by incision. Has been pregnant three times, without any symptoms of miscarriage.

Mrs. M. Dysmenorrhœa and sterility from anteflexion. Incision of cervix. Four pregnancies since, without symptoms of miscarriage.

Mrs. L. Dysmenorrhœa from anteflexion. Incision of the cervix. Since pregnant, and safely delivered after the full time. No symptoms of miscarriage.

Mrs. C. Dysmenorrhœa and sterility from anteflexion. Incision. Case cured. Not since pregnant.

Mrs. C. Vaginismus, dysmenorrhœa and anteflexion. Dissected out the hymen after the manner of Dr. Sims, and operated by incision with Simpson's instrument. Patient cured, but whether she has since been pregnant I have no means of knowing, as she removed from the city soon after.

Mrs. C. Sterility and dysmenorrhœa from anteflexion. Incision as described in case of H. K. W. Case cured. No pregnancy.

Mrs. D. Dysmenorrhœa and sterility from anteflexion. Operated with modification of Civiale's urethrotome, as described in case of H. K. W. Three successful pregnancies since.

Mrs. E. Sterility, dysmenorrhœa, anteflexion, and uterine catarrh. Incision as described in case of H. K. W. Twice pregnant, without symptoms of miscarriage.

Mrs. E., of Texas. Dysmenorrhœa, sterility, anteflexion, and uterine catarrh. Operated by incision with Civiale's urethrotome. Case cured. No means of ascertaining whether patient has since been pregnant.

Mrs. F. Anteflexion and dysmenorrhœa. Same operation. Since pregnant, without symptoms of miscarriage.

Mrs. G. Dysmenorrhœa, anteflexion, vaginismus, and sterility. Dissected out the hymen, and operated by incision of the posterior wall of the cervix and os internum, as described in case of H. K. W. The two operations were not, of course, performed without the proper interval between them. Case cured, but so recent as to render the question of pregnancy one only to be decided by future events.

Mrs. F. Anteflexion and dysmenorrhœa. Operated as in preceding case. Have no means of ascertaining whether patient has since been pregnant.

Mrs. G. Anteflexion and dysmenorrhœa. Same operation. Case cured Not pregnant when last heard from, which was some years ago, and but a few weeks after the operation.

Mrs. H. Anteflexion and dysmenorrhœa, sterility of course. Operated by incision of cervix and os internum, with my modification of Civiale's urethrotome. Cured the dysmenorrhœa, but not the sterility.

Mrs. H. Anteflexion and dysmenorrhœa. Operated as in preceding case. Has been pregnant three times since, and gone the full time without symptoms of miscarriage.

Mrs. W. Anteflexion, dysmenorrhœa, and uterine catarrh, for which she had previously suffered a tedious treatment. Same operation as in preceding case. Cured, but has not since been pregnant.

Mrs. W. Anteflexion and dysmenorrhœa. Operated by incision, with modification of Civiale's instrument. Cured, but not since pregnant.

Mrs. I Anteflexion and dysmenorrhœa. Incision of cervix and os internum. Case cured. Very recent.

Mrs. R. Anteflexion and dysmenorrhœa. Incision of the cervix. Since pregnant, and went full time without symptoms of miscarriage.

Mrs. R. Anteflexion and dysmenorrhœa. Incision of cervix and os internum. Operated by incision, with some subsequent trouble, though not enough to occasion any anxiety, the patient having taken the liberty of removing the packing of cotton and the laminaria.

Mrs. R. Anteflexion and dysmenorrhœa. Operated by incision. Case cured, but no subsequent pregnancy.

Mrs. R. Dysmenorrhœa in consequence of stenosis. Operated by incision. Not since pregnant. In this case there was also a fibroid tumor of the os internum, which had to be broken down by repeated incisions to the centre. Well as ever, with the exception of not having become pregnant.

Mrs. S. Anteflexion and dysmenorrhœa. Incision of the cervix. Since pregnant and safely delivered at the expiration of the full time.

Mrs. V., after incision of the cervix for dysmenor-

rhœa and sterility, has been pregnant three times, and gone the full period without symptoms of miscarriage.

Mrs. W. Anteflexion, dysmenorrhœa, sterility. Addicted to opium. Incision. Case cured. Not since pregnant.

Mrs. W., of East New York. Anteflexion and dysmenorrhœa. Incision. Case cured.

Mrs. M. Anteflexion and dysmenorrhœa. Incision. Dysmenorrhœa cured. Still under treatment.

Such thorough confidence have I in incision of the cervix uteri, when carefully performed, that I employ it almost invariably in virginal cases, in which it is important not to rupture the hymen, and hence the use of the speculum is impracticable. No man can be a successful surgeon who, whatever his theoretical acquirements, has not learned to see with the tips of his fingers. A few of these cases, as they bear upon Dr. Peaslee's papers, I will copy from my case book.

Miss D., twenty years of age. Anteflexion and dysmenorrhœa. Under chloroform to full anæsthesia I found the hymen sufficiently relaxed to be distendible. Introduced the double tenaculum into the os externum, straightening the cervix in such a manner as to admit of the introduction of a pair of curved probe-pointed scissors, guiding them carefully along the passage with the previously introduced index finger, so as to avoid laceration, and trusting the retention in place of the double tenaculum to the hand of an assistant. In this manner I slit the posterior portion of the cervix up or near to the vaginal junction, say within a line of it. Withdrawing the scissors, I next introduced my modification of Civiale's instrument, which can be adjusted to any exact depth of incision, through the os internum, and made one longitudinal incision through the tissue of that body, a line and a half in depth. Next, closing the blade and passing the instrument further up, I made an incision of forty-five degrees in obliquity along the right wall, and another on the left. The three incisions being sufficient to insure considerable dilatation of the cervix, the next step was to introduce a tent of laminaria, the expansion of which would keep the passage enlarged. I removed the tent, as usual, at the end of five days, cleansed the wound with carbolic acid water, and redressed the incision, using chloroform, which, in addition to its anæsthetic value, has the special property of relaxing muscular fibres to such an extent as to admit of considerable enlargement of the passage, without danger of rupturing the hymen. After the incision is healed, I have of late found great advantage in using the bifurcated stem pessary, which contributes to retain the cervix in position until the muscles have fully recovered their tone.

Miss H., nineteen years old. Anteflexion and dysmenorrhœa. Operated under full anæsthesia as in preceding case. Hymen not ruptured. Case cured.

Miss H., sister of preceding, twenty years old. Anteflexion and dysmenorrhœa. Same operation. Case cured without rupture of the hymen.

Miss J., twenty three years old. Operated as before, without rupturing the hymen. Patient married soon after, and has been twice pregnant. In consequence of albuminuria, dropsy, and spasms, she was artificially delivered of the first at the end of seven months. The second was carried the full term without symptoms of miscarriage.

Miss M. Anteflexion and dysmenorrhœa. Incision under full anæsthesia, without rupture of the hymen.

Miss R., twenty-two years old. Anteflexion and dysmenorrhœa. Incision, as in preceding cases. Since married. Has been twice pregnant, and gone the full time without symptoms of miscarriage.

Miss N. Dysmenorrhœa. Same operation, without rupture. Case cured.

Miss R. Dysmenorrhœa. Operated in the same manner, although the hymen was partly ruptured before the treatment commenced. Case cured.

Miss R., sister of the two Misses R. immediately preceding. Dysmenorrhœa and anteflexion. Catamenia were accompanied with spasms every month. Operated with dilating forceps, and introduced the bifurcated stem pessary. As showing the advantage of incision of the cervix, this case has not been successful.

Miss R. Anteflexion and dysmenorrhœa. Operated by incising the cervix as previously described, without rupturing the hymen. Since married, and lately delivered at the full time. No symptoms of miscarriage.

Miss B., eighteen years old. Operated with dilating forceps, under full anæsthesia. Since married and pregnant.

Miss M., nineteen years old. Operated with dilating forceps. No rupture. Case cured.

Miss M., twenty-eight years old. Operated by incision. Case cured without rupture of the hymen.

Miss D. Dysmenorrhœa. Incision under full anæsthesia. Case cured without rupturing the hymen.

In all these cases the incision has been substantially the same, namely, a longitudinal cut of the cervix up to the vaginal junction, and three incision of the os internum, each a line and a half deep, with subsequent dilatation of the cervix with laminaria, expanding in many cases to five-eighths of an inch in diameter. In every case the dysmenorrhœa and anteflexion have been cured, without any serious hemorrhage. Of these cases fifteen have been pregnant and gone the full time. Five of the virgins have since married, with seven healthy pregnancies in all, and not a single case of miscarriage has occurred from inability of the incised cervix to carry the full time of fœtal development. One had premature labor from albuminuria, dropsy and convulsions; and, with the assistance of Dr. Charles Budd, hypodermic injections of ergot, and the forceps, the mother was saved to be healthily pregnant soon after.

I will not trouble the readers of a medical journal with any theoretical discussion of Simpson's operation or the special features introduced by Sims. In surgery, success is the test of merit in every operation, and it is only by a careful analysis of the case-books of practical men that the young practitioner can learn to distinguish between real science and cleverly expressed theory; and I shall, therefore, hope to see the MEDICAL RECORD open its columns to transcripts from the case-books of practical gynæcologists, with a view to contribute to the materials for scientific exactness. I cannot forbear observing, however, that Dr. Peaslee's view rests upon a radical misconception of the part played by the cervix uteri in successful pregnancy. It is not the cervix proper, but the special muscular portion, consisting of circular fibres, at the vaginal junction, that retains the developing embryo. The lower portion is redistributed, and becomes part of the uterine integuments as that organ expands during the progress of gestation, in such a manner that cicatrices of considerable magnitude are completely obliterated by a single pregnancy.

In a recent virginal case, the patient, Miss B., of this city, had anteflexion with stricture of the os internum. Age twenty five years. Hymen unruptured. In delicate health and considerably emaciated. Placing her under the full influence of chloroform, which is very superior to ether as a muscular laxative, and tends

to the reduction of hemorrhage by suspending the *vis a tergo* of the heart, I introduced the index finger of the right hand and passed up a single tenaculum, drawing the os internum downward. Entrusting this to an assistant, I next replaced the single tenaculum with a double one, which I inserted into the cervix, depressing it as far as practicable, and entrusted it to the asssistant. Then, with the right hand I passed in a curved pair of probe-pointed scissors, one blade of which entered the os and cervix, the other remaining posteriorly without, and incised the latter up to the vaginal junction, so as to straighten the canal from above downward. The index finger of the right hand must be the guide in making this incision, and great care must be taken to keep it within due limits. Still retaining the double tenaculum, I next widened and straightened the uterine canal, by introducing into the os uteri internum, and a little beyond it, a concealed uterotome, and making three incisions into the os internum, which is done by withdrawing the guarded blade open, and returning it shut. Of these incisions one was downward anterior, three-fourths of an inch long, and a line and a half deep, and the other two were lateral oblique. A section of laminaria, sustained with a packing of cotton, completed the operation. The hemorrhage was trifling. The laminaria must be occasionally introduced during the progress of the healing, to prevent contraction of the incisions of the os internum. Case cured, without rupture of the hymen.

Yours, very respectfully,

JOSEPH WORSTER, M.D.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from July 23d to July 29th, 1876.

MILHAU, J. J., Surgeon. Leave of absence extended to October 1, 1876, and his resignation accepted by the President, to take effect Oct. 1, 1876. S. O. 148, A. G. O., July 21, 1876.

BACHE, D., Surgeon. Assigned to duty at Angel Island, Cal. S. O. 73, Dept. of California, July 19, 1876.

TILTON, H. R., Asst. Surgeon. To proceed to mouth of Big Horn River, M. T., and report to Brigadier-General Terry for duty with his command in the field. S. O. 88, Dept. of Dakota, July 22, 1876.

HORTON, S. M., Asst. Surgeon. Assigned to duty as Post Surgeon at Fort McHenry, Md. S. O. 143, Division of the Atlantic, July 28, 1876.

MCELDERRY, H., Asst. Surgeon. Granted leave of absence for two months. S. O. 148, C. S., A. G. O.

LIPPINCOTT, H., Asst. Surgeon. Assigned to duty at the Military Academy, West Point, N. Y. S. O. 148, C. S., A. G. O.

GIRARD, A. C., Asst. Surgeon. Granted leave of absence for six months, with permission to go beyond sea, to take effect when relieved by Asst. Surgeon Lippincott. S. O. 148, C. S., A. G. O.

GIRARD, J. B., Asst. Surgeon. Granted leave of absence for one month. S. O. 152, A. G. O., July 27, 1876.

PRICE, C. E., Asst. Surgeon. Assigned to duty at Camp Bidwell, Cal. S. O. 73, C. S., Dept. of California.

WORTHINGTON, J. C., Asst. Surgeon. To report to Commanding Officer Dept. of Arizona for assignment to duty. S. O. 150, C. S., A. G. O.

SPENCER, W. G., Asst. Surgeon. Granted leave of absence for one month. S. O. 106, Dept. of the South, July 27, 1876.

Medical Items and News.

KAKE, OR THE BERI-BERI OF JAPAN.—Dr. D. B. Simmons, of Yokohama, Japan, writes:—"The disease known by the native name of Kake, which has appeared in an epidemic form in the large seaport towns of this country, for the past four years, is beyond a doubt the Beri-beri of India and the Mid-Oceanic Islands.

"The ætiology and pathology of the latter is acknowledged by all writers on the subject to be exceedingly obscure.

"In the investigation of the Japanese disease, we have been able to settle beyond a doubt some important points, which we believe opens a new era in the progress of our knowledge of this subject. We shall refer to the one only at this time which appears to us the most important, viz., *an acute atrophy of the muscles, caused by an amyloid degeneration of their contractile elements.* This fortunately affects certain groups only, and is the true cause of the tedious paralysis which is a leading symptom of this disease. We have in the course of preparation a complete review of the subject, which we hope to complete within a short time."

POWDER TO PREVENT PITTING AFTER VARIOLA.—Dr. Pennavaria, of Ragusa, has succeeded in preventing pitting in several cases of variola by the use of a powder composed of four parts of flower of sulphur and one part of red precipitate. He was led to use it by the success he had had with it in eczema and acne. A thin layer of glycerine is first spread over the pustules as soon as they have reached the period of suppuration, and the powder is dusted over it. The glycerine secures the adhesion of the powder, which causes desiccation and the formation of a crust, and when this falls the skin is exempt from cicatrices.

UNIVERSITY OF MICHIGAN.—The Regents of this University, at a recent meeting, made two new appointments of professors in the Homœopathic College.

INTERNATIONAL MEDICAL CONGRESS, PHILADELPHIA, SEPTEMBER 4–9, 1876.—The International Medical Congress will be formally opened at noon on Monday, the fourth day of September. The sessions of the Congress and of its Sections will be held in the University of Pennsylvania, Locust and Thirty-fourth streets. The General Meetings will be held daily, from 10 to 1 o'clock. The Sections will meet at 2 o'clock. Luncheon for members of the Congress will

be served daily in the University building from 1 to 2 o'clock. On Wednesday evening, September 6th, Dr. J. J. Woodward, U. S. A., will address the Congress on the Scientific Work of the Surgeon-General's Bureau. The Public Dinner of the Congress will be given on Thursday evening, September 7th, at 7 o'clock. The registration book will be open daily from Thursday, August 31st, to Saturday, September 2d, inclusive, from 12 to 3 P. M., in the Hall of the College of Physicians, N. E. corner of Thirteenth and Locust streets, and at the University of Pennsylvania on Monday, September 4th, from 9 to 12 M., and daily thereafter from 9 to 10 A. M. Credentials must in every case be presented. Letters addressed to the members of the Congress, to the care of the College of Physicians, N. E. corner Locust and Thirteenth streets, Philadelphia, during the week of meeting, will be delivered at the University of Pennsylvania. The Secretaries of State and Territorial Medical Societies are requested to forward, without delay, to the Chairman of the Committee on Credentials, I. Minis Hays, M.D., 1607 Locust street, Philadelphia, lists of their duly accredited delegates to the Congress. Delegates and visitors intending to attend the Congress are earnestly requested, individually, to notify immediately the same Committee. This information is desired to facilitate registration, and to ensure proper accommodation for the Congress. Members intending to participate in the public (subscription) dinner of the Congress will please notify the Secretary of the Committee on Entertainment, J. Ewing Mears, M.D., 1429 Walnut street, Philadelphia. Gentlemen intending to make communications upon scientific subjects, or to participate in any of the debates, will please notify the commission before the 15th of August.

International Medical Congress at Philadelphia.—The Epidemiological Society of London has chosen Dr. Edwin Howard as its delegate to the Congress. The Obstetrical Society of Dublin has elected Dr. T. More Madden. Profs. Nicolaysen and Hjort have been elected delegates by the Norske Medicinske Selskab.

Death of Dr. L. De Forrest Woodruff.—At a special meeting of the Medical Board of Charity Hospital, held July 13th, 1876, the following Resolutions were adopted:

Whereas, our Colleague, Dr. Lockwood De Forrest Woodruff, has been removed from our number while in the performance of his duty, therefore

Resolved, That in his death, the Hospital has lost the services of one who was earnest in its interests and vigilant in all that pertained to its honor and usefulness.

That his death, contracted in the Hospital service, was a sacrifice that this Board honors as typical of the lofty professional spirit which he so eminently embodied.

That we shall miss the companionship, aid, and counsel of one who was thus, in all the qualities of physician, colleague, and friend, pre-eminent.

That we mourn with his family, while with them we bow to the wisdom of the Providence that has summoned him from our midst.

Le Roy M. Yale, M.D., *President.*
Frederick R. S. Drake, *Secretary.*

Dr. R. D. Arnold, of Savannah, Ga., one of the founders of the American Medical Association, and one of the committee who framed the Code of Ethics, died July 19th, of phthisis pulmonalis, in the sixty-eighth year of his age.

William R. Warner & Co.—The prize medal at the Chilian World's Fair, was awarded to Messrs. William R. Warner & Co., of Philadelphia, for the superiority of their sugar-coated pills.

Hirschfeld.—*Le Monde Russe* announces the death of M. L. Hirschfeld, the eminent anatomist, at Varsovia, on the 28th of April. M. Hirschfeld was born at Varsovia in 1814, and prosecuted his studies in the Universities of Breslau, Berlin and Paris.

Judgment against an Apothecary.—An apothecary and his clerk have recently been condemned, in Paris, to one month's imprisonment, and to pay $10 fine and $400 damages, for a mistake in filling a prescription. Arseniate of soda, a very violent poison, was given in mistake for phosphate of soda, and the patient's health is still seriously impaired in consequence. The excuses of the pharmacist were not accepted, because he should have kept his poisons under lock and key.

Stromeyer.—The history of Stromeyer has been an eventful one: Born in 1804, he studied medicine from 1822–1826 at Göttingen and Berlin; then had a position as surgeon at the Royal Court of Hanover. In 1838 he was made professor of surgery at Erlangen, and afterwards at Munich and Freiburg. In the German-Danish war, 1848–50, he served as chief-surgeon, holding at the same time the professorship of surgery at Kiel. After giving up his academical work, he took the position of a general surgeon-in-chief (General Stabs-Arzt) of the Hanoverian army. After the German war, 1866, he retired to a most brilliant private practice at Hanover; though many honorable official offers were made to him. His numerous excellent works, mostly on military surgery, are well known. His last work, Memoir of a German Physician, Hanover, 1875, is of great value, being a criticism of the most eminent medical men and institutions of this century. Moreover, Stromeyer was the first who practised subcutaneous tenotomy, 1838. *

He died at Hanover, June 15th, of cerebral hemorrhage, while preparing himself to visit this country and institutions.

Homœopathy in the University of Michigan.—The following resolution has been adopted by the Faculty of the Rush Medical College: "*Resolved*, that the time and attendance of students upon Lectures of the Medical Department of the University of Michigan, up to, and including, the last regular session of that College, may be recognized as part of the requisites for graduation in this College; but such time and attendance shall not hereafter be accepted, so long as the teaching of Homœopathy, in whole or in part, shall be included in the course of study at that Institution."

Dr. F. K. Bailey.—Died at Knoxville, Tenn., June 17th, 1876, Dr. F. K. Bailey, in the sixtieth year of his age.

Dr. Bailey received his doctorate from Castleton Medical College, Vermont, in 1837, and began his professional career the same year, locating in Michigan, where he continued his labors for a period of twenty years, with that success which is ever an attendant upon the faithful discharge of duty. Early in the war, he

* L. Stromeyer: Beitrage zur operativen Orthopadie; Hanover, 1838.

entered the United States service, being located the greater part of the time at Quincy, Illinois, in charge of the hospital at that place. At the close of the war Dr. Bailey located in Knoxville, Tenn., where, by his assiduous attention to the duties of his profession, his untiring devotion to his patients of all classes, whether rich or poor, he won for himself that name which is rather to be chosen than great riches; and soon found himself in possession of a large and extensive practice.

Among his professional brethren his demeanor was that of the scholar, the gentleman, and the Christian; and he enjoyed the confidence, love, and esteem of all his confrères.

Dr. Bailey was a large contributor to the medical literature of the day, and as such was highly esteemed. The charming grace of his cultured pen has left an indelible record of his attainments as a learned physician; and the works that he has left, replete with wisdom and research, remain an enduring monument to his exalted worth. J. P. P.

The Archives of Clinical Surgery is the title of a new New York Monthly, edited by Edward J. Bermingham, M.D., of this city. The first number, which is before us, is full of interesting and valuable material. Routledge & Co. are the publishers. Subscription, $4.00 per annum.

Ménière's Disease treated by Quinine.—Charcot has recently given large doses of quinine—from seven to fifteen grains a day for six or seven weeks—in two cases of Ménière's disease, with the result of enabling the patients to go about with security by themselves. He was led to give it in the hope that the ringing in the ears produced by the excessive doses of quinine might deaden the subjective noises in the ears dependent upon the disease.

Two New Sources of Lead Poisoning.—In the *Gazette Méd.*, of May 6, 1876, Dr. Gibert called attention to two new sources of lead poisoning. In one case the editor of a newspaper had suffered for two years from severe gastric disturbances, the explanation of which was ultimately found in a lead line on the gums, and the supply of the poison was found in the red-lead coloring of the stamps which the patient moistened with his tongue every day in large numbers. In the second case the patient consumed so many of the little French *cachous*, such as are used by smokers, as to become poisoned by the lead in the metallic film with which they are "silvered." On chemical analysis each box was found to contain about a third of a grain of lead.

Homicidal Handwriting.—Under this heading the London *Lancet* refers to the careless manner in which physicians are in the habit of writing their prescriptions, and gives a case in point: A gentleman received a prescription for a cough, one of the ingredients of which was benzole rect. By the merest good luck the recipe was properly compounded. Some time afterwards the patient presented the same prescription to another chemist, who read the ingredient referred to as benzoli *nit.*, remarking upon the largeness of the dose. The patient assuring the compounder that he had taken the dose named, without bad effects, it was given to him. The result was that he barely escaped with his life. The *Lancet* truly says: "The whole blame of the accident must be attributed to the prescriber. The practice of relying on a particular chemist to interpret bad writing is very objectionable, and cannot be too strongly condemned. Every prescription should be legible at a glance."

The Paris Faculty and Competitive Examinations.—Several times since the abolition of competitive examinations for professional appointments in Paris, several efforts have been made to restore the concours. The last attempt in this latter direction was lost by a deliberate professorial vote.

Medical Examination of Schools.—The medical profession of Liverpool are warmly advocating the medical examination of school children, with the view of preventing the spread of infectious diseases.

The Army Medical Hospital.—The *Lancet* speaks in very commendatory terms of the Army Medical Hospital at the Centennial Fair.

Government Hospital for Insane, Washington, D. C.—Dr. Nichols, the medical superintendent, has been exonerated by the Congressional Committee from all blame concerning any mismanagement in his asylum.

Anti-vivisection in England.—The medical profession are still actively fighting the proposed Anti-vivisection Bill, notwithstanding that it has been discovered that a goodly number of physicians openly oppose the action of their brethren.

Death of the ex-Sultan.—Dr. E. D. Dickson, physician to the British Embassy, Constantinople, reports, in the *British Medical Journal*, the circumstances connected with the death of the ex-Sultan. It seems that his Majesty had been suffering for a long time with mental hallucinations. These were so strongly marked towards the end of his life that every weapon with which it was thought he might injure himself was carefully taken from him. On the morning of his death he asked for a scissors to trim his beard. This demand was referred to his mother, who, little thinking what use he was going to make of them, sent him her own scissors and a hand mirror. The scissors were small and very sharp. On receiving these things he sent all his attendants (females) out of the room, and put an end to his existence by cutting the blood-vessels in his arms. "The direction of both of the wounds was oblique from above downwards and from within outwards, and their edges were jagged. That in the left arm was deep. I passed my forefinger into it down to the very joint. The skin, the superficial veins, and the deep-seated tissues were cut through, and the ulnar artery laid open but not entirely divided. The wound in the right elbow-joint was superficial, cutting only across the skin and superficial veins. No other injury whatever was discovered on his person."

Dr. Ernst Leyden, Professor in the University of Strassburg, has been appointed to fill the vacancy in the University of Berlin caused by the death of Professor Traube.

Cremation.—A Congress of the supporters of cremation was held at Dresden, June 7th. Four hundred members were registered. It was decided to erect a building for cremation in Gotha, and twenty-three hundred dollars was subscribed.

Death of Ehrenberg.—Prof. C. G. Ehrenberg, of Berlin, the distinguished microscopist, died recently, at the age of eighty-one years.

Animal Vaccination.—A correspondent of the *British Medical Journal* very innocently asks the question, "if vaccination direct from the cow is now practised. If so, by whom, and with what result?" Very evidently the medical reading of this gentleman has been quite limited.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, August 12, 1876.

THE MEDICAL AND SURGICAL HISTORY OF THE WAR. VOL. II.*

THE second volume of the Surgical History of the Rebellion has at length made its appearance, and the anxious expectancy of the profession in regard to the value and extent of its contents is destined to be most satisfactorily realized. Although we have said enough of the previous volumes emanating from the Surgeon-General's office to give our readers a prospective idea of the scope of the present one: and although we have been preparing ourselves against any surprise, we confess ourselves somewhat bewildered in our attempts at a description of its completeness as a book of reference, its accuracy as a scientific record of surgical progress during the late war, and its intrinsic value as a text-book for military surgeons.

It is now pretty generally acknowledged that America holds the surgical sceptre of the world; and if there be any doubts as to the validity of our claims to this honor, they can be very triumphantly dispelled by a careful study of the volumes which have recorded our military experiences. When the idea of writing up the history of our surgical achievements during the rebellion first presented itself to the Surgeon-General, the task was considered to be of such magnitude that anything like systematic completeness seemed like the wild dreams of a crazy enthusiast; but now that the most extravagant expectations of the most sanguine are matters of fact, we cannot be too lavish in our praise of the wonderful perseverance which has brought about this brilliant culmination. It will be recollected by such as are acquainted with the first volume of this series, that it contained a description of over forty-nine thousand cases of injuries of the head, face, neck, spine, and chest. In the present volume, under the same able editorship of Assistant-Surgeon Geo. A. Otis, the account of these wounds and injuries is continued, according to their regional classification. A faint idea of the marvellous completeness attained and immense labor expended in the present work, can be gained, when we consider that eighty-five hundred and thirty-eight cases of wounds of the abdomen are tabulated and described, and details of six hundred and ten of them recorded: thirty-one hundred cases of wounds of the pelvis are enumerated, and six hundred and ten detailed; twelve thousand six hundred and eighty-one cases of flesh wounds of back are also tabulated, and eighty-eight thousand seven hundred and forty-one cases of wounds of the upper extremities are given, with details of eight hundred and seventeen; together with the principal facts concerning thirty-seven hundred and twelve excisions, and eighty-two hundred and forty-five amputations. We cannot attempt any critical analysis of its contents, nor can we present even in outline the conclusions which have been drawn from the experiences which it records, as these would of themselves swell an ordinary article into the dimensions of a good-sized text-book. It is, in truth, one of those works which are so encyclopædal in character, that each chapter is a treatise in itself; and must be separately studied and digested before any justifiable criticisms can be made or any definite opinions of the relative value of the different subjects can be expressed.

To dismiss the consideration of the volume with the hackneyed commendations so usual in book notices, would make it appear to the casual reader that there was nothing for any extraordinary comment; yet, in the present instance, such a course is forced upon us, as one of the inevitable accidents of time and circumstance. When, however, we speak of the work, in a general way, as an event in the surgical history of our nation; as a vindication of our claim as leaders in surgical knowledge and expedients; as the most remarkable contribution of its kind that has been made to science—we cannot conscientiously open ourselves to any blame for exaggeration of its merit or for extravagance in its praise.

It is alike impossible to estimate the influence which these records will have upon the advancement of military surgery in every portion of the globe. For years to come these histories will be the foundation-stones upon which the practice of army surgeons will be built, and will serve as starting-points of new investigations for every enthusiastic searcher after new truths, and every conscientious founder of new doctrines. The methods of treatment which have been recommended, founded as they are upon the observation and study of thousands of cases, will for a long time to come be established and undebatable until an equal array of contradictory data can be presented.

* The Medical and Surgical History of the War of the Rebellion. Part II., Vol. II. Surgical History, prepared under the Direction of Joseph K. Barnes, Surgeon-General U. S. Army, by George A. Otis, Assistant-Surgeon U. S. Army. First Issue. Washington: Government Printing-Office, 1876. 4to, pp. 1024.

As there has been no attempt at theorizing on the part of Surgeon Otis, but merely a desire to draw the legitimate conclusions from the facts recorded, there is no danger that the influence of the work as an absolute authority will soon be lost. To it every military surgeon will go, as a storehouse of the most extensive experience on record; and from it he will derive all the necessary precedent for the simplest as well as the most formidable of the operations ever performed upon the field or general hospital. A special value of the work is the great number of elegant illustrations, taken direct from life subjects and from pathological specimens in the Army Medical Museum. Done in the highest style of the art, they give an accuracy to the detail of appearances which eclipses any attempt at description in the text, and impresses upon the mind points in a given case which would otherwise be perhaps entirely lost sight of. All these specimens, being duly numbered, can be examined and studied as such in the Army Cabinet.

The marvellous success of this enterprise, while it reflects credit upon all concerned in its inception, affords a remarkable example of the benefits of governmental endowment. By no other means could such a work have been carried on, and in no other way could the results be made available to science. It is a matter of congratulation that such a publication, so satisfactory to those for whom it was intended, proves so unmistakably the wisdom and forethought of our legislators, and establishes such a brilliant precedent for other undertakings of similar scientific value.

THE DENTISTS' FUTURE.

The dentists of Pennsylvania have held their annual meeting at Philadelphia within a few days past. The medical profession is interested in their deliberations, chiefly on account of the efforts they are making to elevate their standard of education by association in some form or other with medical schools. Each State and local dental society will doubtless discuss the same important question in due time. In the present condition of things, the dentist is puzzled to know whether he is practising a specialty which is simply an offshoot of the great domain of medicine, or whether it is a distinct science and art, independent and standing on its own merits. In other words, a preference is expressed by many of these gentlemen to develop into something more than mere mechanical workers in enamel and dentine. To be oral surgeons savors of much greater dignity, and gives them a decidedly more elevated professional status. Many of the more accomplished among them are sincerely anxious that their duties shall be amplified, so that they shall be something more than handlers of mallets and files, ruthless destroyers of aching nerves, fillers of decayed cavities and extractors of worthless snags of once valuable ivories. Hence has arisen the question for discussion in dental societies everywhere, whether dentistry shall not be taught in medical schools. Practical steps have indeed been already taken to test the feasibility of this measure; for we read in the proceedings of the Pennsylvania society, that professors of medical colleges from that State and from New York were personally present, or communicated their views by letter, expressing their desire to add dental chairs to the curriculum of study, so that dental and medical students might be co-educated. It was stated that, so far as the University of Pennsylvania was concerned, nothing but the indifference of its Trustees stood in the way of the accomplishment of this change. It was especially urged by one professor, that the connection of diseases of the teeth and those of the nervous system was well worthy of study in such institutions. We believe that two points must be fully considered previous to a solution of the question. Is it desirable that dentists shall receive a thorough medical education? Is it expedient to teach dental surgery, in all its details, to medical students? So far as we can judge, the dentists seem more anxious about the matter than the doctors. Unless some decided initiatory step is soon taken by a medical school, the fusion may be long postponed, discussion being coupled with inaction from year to year. The terms of the agreement for mutual attachment, by which dental colleges will be absorbed and wholly disappear, will at least be interesting. So much personal sacrifice will be involved, that we confess to some curiosity as to the details by which it is to be effected.

Reports of Societies.

AMERICAN MEDICAL ASSOCIATION.

Section of Medical Jurisprudence, Chemistry, and Physiology.

This Section was only in session one day, Wednesday, June 7; Chairman, Dr. E. Llyod Howard, of Maryland; Secretary, Dr. D. A. Morse, of Ohio.

APPLICATION OF PHOTOGRAPHY TO MICROMETRY.

A paper was presented by Dr. J. J. Woodward, U. S. Army, on "The Application of Photography to Micrometry, with special reference to the Micrometry of Blood in Criminal Cases." He described in technical detail his very interesting method of obtaining photographs of microscopic objects, pointed out some of the defects of other processes, and alluded to the employment of photographs of blood-stains in the court-room. He criticised the spirit of exaggeration of certain writers who claim or insinuate that they possess the power of unerringly discriminating human blood from that of other animals in the dried stains submitted to examination in criminal cases. He cited Prof. Gulliver's recently revised table of measurements of corpuscles of the vertebrata (published in the Proceedings of the Zoological Society of London, June 15, 1875) in confirmation of the futility

of attempting to distinguish human blood from that of other animals in dried stains in such cases. The average of all measurements of human blood he had found rather larger than the average of all the measurements of dog's blood; but it is not rare to find specimens of dog's blood in which the average size of the corpuscles is larger than that of many samples of human blood. He concluded with a table of measurements of the red corpuscles of man, the dog, and the guinea-pig, photo-micrographically measured by his method; and exhibited photographic specimens of corpuscles. The comparative sizes were shown to vary with different specimens; so much so, indeed, that it was sometimes impossible to tell from the examination whether the particular specimen belonged to the guinea-pig, to the dog, or to man. He stated that it was his intention to prepare a series of photographs of moist blood, and of blood soaked out from dried stains, as in criminal cases.

Dr. Didama, of New York, suggested that pig's blood would be more interesting than guinea-pig's, and more likely to be a matter of criminal moment. Would Dr. Woodward be willing to swear to the difference between pig's and man's blood, after the drying process and after shrinking had taken place?

Dr. Woodward said it would be easy to distinguish them if we had specimens when fresh, and treated them both alike, and knew more about the conditions leading to shrinkage and contraction than we know now. He then exhibited photographs in which the human blood, acted upon by reagents, had shrunk to the size of a pig's corpuscles; but you may have specimens of the latter which have not shrunk, and the addition of a drop of water to a drop of fresh human blood will make its corpuscles smaller than those of the pig.

Dr. Didama asked whether the Doctor would be able to pick out the corpuscles of human and dog's blood, if both had undergone the same shrinkage.

Dr. Woodward replied, decidedly not. The smallest corpuscles of human blood are smaller than the largest corpuscles of the dog's blood.

Dr. J. G. Richardson, of Philadelphia, after complimenting Dr. Woodward on his success in photo-micrography, quoted from his own paper on the value of high powers, previously published, showing that the assertion of Virchow, that a man's life should not be put in question on the uncertain calculation of a blood corpuscle's ratio of contraction by drying, was not a fair statement of the point at issue; for if the red blood-corpuscles of oxen, horses, pigs, sheep, etc., are all much smaller than those of man, no degree of contraction would render the stains in which they occur more liable to be mistaken for man's blood. The cell wall of a red blood globule is incapable of any marked expansion by drying or moistening with the fluids recommended for the examination of blood-stains. The slight increase of size already referred to as occurring in the desiccation of a thin film of blood forms only an apparent exception, and is probably due to change of shape during the complete flattening out of the discs as they lose their contained water. The only danger is, if the cell walls contract, we might, by a possible error in diagnosis of the origin of a blood-stain, contribute to a criminal's escape, never to the punishment of the innocent. Were it possible for the corpuscles of the ox, pig, sheep, etc., to expand to the size of human corpuscles, he would be the first to refuse to make a diagnosis in criminal cases. He asked Dr. Woodward whether he had ever seen any marked expansion of the corpuscles of human or animal blood occur, whilst following out his method for the examination of blood-stains with the three-quarter per cent. salt solution.

Dr. Woodward said that he had not, but had frequently observed rapid and almost instantaneous contraction of blood-corpuscles, treated with various reagents. The expansion occurs while drying, and before getting into the hands of the experts.

Dr. Richardson stated that he had never undertaken to say absolutely from microscopic investigation alone, that a given specimen was human blood; but when a prisoner declared that the spots upon his knife, on which were corpuscles averaging more than $\frac{1}{4000}$ of an inch in diameter, were from a sheep, microscopic examination could detect the falsehood, a sheep's corpuscles being comparatively small.

Dr. Woodward said that if he found a series of corpuscles in a stain measuring on an average 300 or 295 millionths of an inch in diameter, he would grant that a microscopist might swear they were not those of sheep's blood.

Dr. Richardson thought that Gulliver had admitted that, in some instances, a diagnosis might be made, by means of micrometry, between human and sheep's blood, and requested Dr. Woodward to read the passage already referred to, as follows: "As before noticed, the magnitude of the corpuscles in a single species, not excepting the human, is liable to variations within certain limits; and there commonly appear in one field of vision of the same corpuscles, differences amounting to at least one-third larger and smaller than the average. Hence, as regards the medico-legal question, however truly a careful observer (Dr. Joseph G. Richardson, *Monthly Micros. Journal*, Sept., 1874) may have distinguished, by comparative measurements of the corpuscles, stains of human blood from those of the sheep or ox; this kind of diagnosis, as Dr. J. J. Woodward observed, (*Monthly Micros. Journal*, Feb., 1875) would be ineffectual in some probable and more possible cases. It should be borne in mind, too, that in the apyrenemata the membranous bases of the blood discs, when deprived of their color by maceration in water, are about a third smaller than the unaltered corpuscles."

The chairman renewing the question whether Dr. Woodward could decide positively between human and pig's blood-stains, the latter replied that in a decision, as a mere matter of interest between gentlemen, he would be willing to give his opinion as to one or the other; but if it was a case in which life was involved, the possibilities of mistake are too great, and he would probably feel differently.

The paper of Dr. Woodward was referred to the Committee of Publication, and the Section adjourned *sine die*.

Section on Surgery and Anatomy.

The Section met on Tuesday afternoon, June 6; Dr. Alonzo Garcelon, of Maine, Chairman; Dr. E. F. Easley, of Arkansas, Secretary.

Treatment of Pott's Disease of the Spine.

Prof. Sayre, of New York, read a paper on the treatment of Pott's disease of the spine. He was of the opinion that the causation was generally, if not always, traumatic, and not necessarily of tubercular or constitutional origin. He gave a full description of the manner of examination to establish an early diagnosis before the occurrence of deformity. The treatment should be by extension of the spinal column, by suspension of the body by a sling under the arms, occiput, and chin, and elevating it by a compound

pulley; retaining the body in this extended position by a plaster-of-Paris bandage, applied on a very tightly fitting shirt, and laying the patient on an air or water bed until the plaster has set or hardened, when he can generally walk well without assistance, and the respiration becomes deep, full and free, but diaphragmatic, the perineum ascending and descending synchronously with the diaphragm. The short jerking respiration is immediately relieved. The skin is retained absolutely at rest, and so are the ribs, and recovery takes place the same as in fracture—by rest—recovery being prevented if motion is allowed.

After reading the paper he exhibited the suspending apparatus, and presented several cases treated by him. He thought that doctors should treat their patients themselves, and not send them to specialists. The cases shown were far advanced, but it is very important that this treatment should be entered upon before the occurrence of deformity. At the same time give the patient the very best constitutional treatment, without drugs, if possible. The thinner your bandage is applied the better; the ordinary bandage used for fractures is too tight and heavy. Some of these same facts had previously been given, in anticipation, in a report of a clinical lecture delivered by him; but now he could speak positively from a large number of cases that had since come into his hands for treatment.

Dr. Quimby, of New Jersey, inquired whether respiration was not sometimes interfered with.

Dr. Sayre said that a projecting sternum or projecting points might be guarded and bent in sometimes. An air bed was also a great assistance; or pads might be used.

Dr. Benj. Lee, of Philadelphia, in seconding the motion to refer the paper, which he highly commended, to the Publication Committee, stated that we must treat caries of the spine exactly as we would treat a fracture. He had not resorted to Dr. Sayre's method, but should do so at a favorable opportunity. He believed that too many of these cases are unrecognized by medical men in their early stages. Dr. Sayre's suggestions as to early diagnosis were very important. We were formerly taught that the diagnostic point in Pott's disease was the pain produced by pressure on the spine; but if you place a patient on his face, and make pressure on the projecting portion of the spine, you separate the bodies which are pressing together, and thus relieve the pain. He claimed for himself the credit of having been the first to point out the importance of gastralgia as an initial and characteristic symptom. The idea of making a suspension apparatus, "a hanging machine," as Dr. Sayre calls it, was first introduced by Prof. J. K Mitchell. It fell into disuse, but Dr. Lee had revived it at the suggestion of Dr. M.'s son; the patient daily suspending himself for a certain length of time, so as to produce complete extension of the spinal column and relieve the pressure at the seat of disease.

Dr. Quimby differed with Dr. Sayre in ascribing these cases to a traumatic origin rather than to a strumous condition.

Dr. Sayre said he never taught that doctrine; he meant that a child with a constitutional taint would have disease developed and localized in his spine by very much less traumatic force than a robust, vigorous one.

The paper was referred to the Committee on Publication.

Dr. Easley, of Arkansas, said that Dr. Sayre and Mr. Bryant, of London, had shown more clearly than any one else that there is no necessary connection between scrofula and diseases of the bones; but thought the former gentleman went too far in ascribing so much to traumatic causes.

Dr. Dowell, of Texas, read a paper on Hernia, from the Transactions of the State Medical Society of Texas, giving an account of his new operation for its radical cure. It was referred to the Committee on Publication.

TREATMENT OF COLLES' FRACTURE.

Dr. Henry A. Martin, of Boston, described a splint for the treatment of Colles' fracture. It was invented by Dr. W. F. Carr, of New Hampshire, but had been very successful in his hands, little or no deformity resulting. The fault with the splints generally used was, that the radius was treated as if it was a straight instead of a curved bone. Simple fracture by this splint is completely relieved of pain, and there is no stiffness of the metacarpo phalangeal articulations. The patient from the first handles his knife and fork at meals—awkwardly, it is true—and can make some little use of his hand after the first week. During the latter period he merely confines the carpus by plaster strapped behind it. The dressings are removed in four or five days. Perfect union takes place much earlier than the period laid down in the books. The whole principle involved is to treat the radius as a concave bone, and supply the exact form of pad on which it should rest. The oblique cross-bar relieves the usual tendency to deformity towards the radial side. The splints are padded with roll cotton merely to make them softer, not to change their form. If the wrist has been sprained, these splints give perfect rest. They could be made very cheaply.

Dr. Dibrell, of Arkansas, said that one of the great sources of trouble was rupture of the annular ligament.

Dr. Martin stated that this form of splint met that difficulty also.

Dr. Sayre entered his protest against unnecessary re-examination of fractures. The general principle in fractures was to adjust the apparatus, and then regulate it; and keep it there until you get a chance to examine it.

Dr. Martin was as much opposed as any one to this readjustment, because it involved the danger of non-union.

Dr. McClurg, of Pennsylvania, also condemned it as meddlesome surgery, and thought it was unnecessary to see such a case more than three times, no matter what splint was used. The surgeon should know exactly what to do as soon as he had determined the nature of the injury; and if he applied his apparatus on correct principles, he would be successful.

Dr. Dubois, of New York, had improvised a splint for this fracture by taking a shingle and holding it by a bandage with a stick at the end, laying it on obliquely as this round stick is put on, and then putting a pad upon the splint, and winding around a bandage and making it solid.

Dr. Quimby thought Dr. Carr's splint would put the hand in a very awkward position. He didn't think it would be applicable where there was much inflammatory action. He regretted that the experience of Dr. Hamilton, in cases of Colles' fracture, as quoted by Dr. Martin, had been unfavorable, many of them resulting in deformity.

On motion, Dr. Martin was requested to prepare a paper on the subject, to be referred to the Committee on Publication.

A NEW TRUSS.

On Wednesday afternoon, Dr. Easley, Secretary, presented a little truss sent him by Dr. Ives, of New

York, having a broad lever on the upper portion of the pad, which gave it the name of the "lever pad truss." The band is a strong piece of elastic, and the flat lever coming against the abdomen prevents the apparatus from slipping out of place.

Dr. Ives said he had had much satisfaction with this truss in about a dozen cases. It does away with the annoying strap between the legs.

TREATMENT OF FRACTURES.

Dr. Plummer, of Rhode Island, wished the discussion on fractures of the femur, begun at Detroit, revived here. Dr. Sayre had then taken the ground in favor of their treatment by the triple inclined plane. After citing some successful cases in illustration of the advantages to be derived from it, he referred to Dr. Treswell's splint as that he is in the habit of using, with a joint that overlaps, and a cog-wheel for necessary extension, and arranged to vary the angles of the body and of the thighs.

Dr. Keller, of Kentucky, said that we can only get perfect apposition by the triple inclined plane, and cited two recent cases in confirmation. Much of the success depends upon the muscular development of the patient, being much more probable in an extremely relaxed muscular system. As urged by Dr. Sayre, we must first secure apposition, then fixation. Splints are instruments of torture to patients. He believed, in the cases mentioned by Dr. Plummer, that anything that could be moulded and adapted perfectly to the prominences and depressions of the patient would fulfil the indications for successful treatment. After referring to the difficulties of diagnosis in intra-capsular fractures of the thigh, he said that it was a slur upon surgery to state that we cannot have bony union in old women with intra-capsular fracture. The fault was, we too often attempted it with appliances movable at the will of the patient.

Dr. Gray, of Buffalo, referred to the employment of adhesive strips for the perineal band, at the Buffalo Hospital, and to a case of dislocated hip reduced after nine months.

Dr. Plummer again alluded to the advantages of the treatment referred to by him, in the greater comfort to the patient.

Dr. Keller said there was no necessity for shortening to occur, if there was proper apposition.

PIROGOFF'S AMPUTATION.

Dr. Addinell Hewson, of Philadelphia, read a paper on Pirogoff's amputation, and showed several cases performed by him. He briefly sketched the early history of Syme's amputation to save the leg, and the advantages claimed for it by that surgeon in the five papers on the subject which he published in 1843 to 1847, in the *Edinburgh Medical Journal*. Pirogoff's operation for traumatic cases was suggested eleven years later than that of Syme. The Russian plan is that of a resection where the os calcis is not involved; both have claims to originality.

The various modifications of these operations, detailed by Erichsen, Lister, Hamilton, and others, were alluded to, and commented on for the following reason: Syme's purpose was to make the plantar flap long enough to preserve the posterior tibial artery beyond its point of division; they have disregarded this very important point, and thus ignored the principle of Syme's operation, of preserving entire the thick integument of the heel to form a cushion for the stump. Dr. Hewson then referred to the bad results that sometimes ensued from not exactly following Pirogoff's directions, and described in detail the various steps of the operation, pointing out at the same time the errors to be avoided. Dr. H. made it a rule to include in the plantar flap all the vessels possible—seven important vessels. He employed acupressure and torsion, with his compound forceps, instead of ligatures; has never had secondary hemorrhage. He generally used three silver stitches, intermediate strips of tarlatan gauze, held in place by collodion applied at their extremities, and over this a dry dressing of powdered clay or salicylic acid, held in place by bibulous paper or cotton wadding. The dressing is only disturbed at the end of a week to remove the stitches. Dr. Hewson then took occasion to renew his advocacy of the earth dressing, with all proper attention to cleanliness, and to laud the disinfecting powers of salicylic acid.

Dr. Quimby commended the dressing, but stated that in 1869 he had brought to the notice of the Association an operation which he thought preferable, especially in young subjects. He mentioned several cases in illustration, and called upon Prof. Post for his views in regard to it.

Dr. Post said that he had seen some of the cases alluded to. The great feature of Dr. Quimby's operation is that it leaves the anterior part of the leg perfectly intact. It did not, at first, seem to him proper to bring the wounded surface of the bone down in contact with the natural extremity of a bone covered with cartilage. It was like yoking an ox and an ass together. The danger from dividing the cellular structure of the bone in Syme's operation is avoided in Dr. Quimby's. The most eminent surgeons of New York have been satisfied with the results. The advantages were that the wound healed properly, in six weeks, the patient being able to bear his full weight on the limb, the operation being performed with facility.

Dr. Darby, of New York, said that he had been in the habit of referring to it in his lectures, as superior to Pirogoff's. In the latter operation he did not make the cut so far forward towards the toes as Dr. Hewson had stated.

Dr. Maclean, of Michigan, said, that for disease Pirogoff's operation is an unsound one fundamentally. If you leave any part of the bones of the ankle in scrofulous conditions here, the disease is sure to return. In railroad crushes, it is a different matter. Syme's amputation showed better results in disease. The accumulation of fluid in the stump is prevented by making a longitudinal slit and introducing a tent.

Dr. Hewson stated, that Pirogoff's cases were those of injury; those of Syme at the great infirmary of Edinburgh were consequent on diseases of bone; and it was but natural that he should generalize his operation, even after Pirogoff's was made known. Dr. Hewson then described more particularly the direction of the incisions, etc.

Dr. Quimby had had several of these operations in his practice, all of which healed by the first intention.

Dr. James R. Wood, of New York, said, that Syme's method was his favorite amputation, or sometimes a modification of it, where great laceration of the integuments existed, the ingenuity of the surgeon being taxed to cover the bone with integument. He had been told by the Surgeon-in-chief of the Russian Army that he preferred Syme's. The operation must be performed to avoid shortening of the limb. He seldom cut into a cartilage; the flow of synovial fluid would prevent union. Dr. Hewson, he stated, closed the wound at once, union taking place by the first intention. Dr. Wood kept everything open, making large flaps, which would shrink very much. He used

carbolic and salicylic acids. He never lost a drop of blood during the operation. Dr. Hewson's results were beautiful, his success a eulogy of his treatment, his stumps worth a visit to Philadelphia to see.

The thanks of the Section were tendered Dr. Hewson for his valuable paper, which was referred to the Committee on Publication.

SUSPENSION IN SPINAL CURVATURES.

Dr. Benjamin Lee, of Philadelphia, introduced a little girl, twelve years of age, illustrating the safety and feasibility of suspension in the treatment of spinal curvatures. The apparatus shown was a strong framework, from the middle of which was suspended his "spinal swing," being a rope passing over a pulley, carrying at one end a steel bow, to which are attached straps, to support the chin and occiput, and at the other wooden ovals to serve as handles. The head straps being so adjusted as to make equal traction on the chin and occiput in the line of the spinal axis, the patient, taking hold of the handles, drew down upon the rope until her feet were lifted from the floor, and she swung freely, half the weight being supported by the neck, and half by the arms. She then drew herself up hand over hand until her head nearly touched the pulley, and then slowly let herself down again. He desired to show that the method of suspension was a simple and pleasurable process. The amount of traction used was at the option of the patient. At first the child should use it for only ten minutes, but should gradually increase it to half an hour, twice daily.

A delegate inquired whether the same effect might not be obtained by the arms, or under the arms, as by using the neck or head.

Dr. Lee replied, that having it in a direct line of the spinal column, had more effect than if the force was distributed. In many cases the disease is above the shoulders.

Dr. Holden, of Vermont, remembered several years ago hearing Dr. Sayre, in a case of dislocation in the cervical region, caution his class about lifting children by the head, and thus causing dislocation.

Dr. Sayre said, the cases were entirely different as to the mode of suspension. The whole weight is sustained by the ligaments of the neck in the case referred to by Dr. Holden.

PERMANENT DRESSINGS OF GLUE IN FRACTURES.

Dr. R. J. Levis, of Philadelphia, described to the section a new and inexpensive method of applying a fixed dressing, used by him at the Pennsylvania Hospital; being ordinary glue, which hardens with great rapidity, to which oxide of zinc is added, until the mixture is rather white. Any kind of material, even a piece of blanket, can be used. (Specimens of discarded dressings thus made were exhibited.) Experiments were being made to determine the proportion of the oxide required. Too much of it makes the glue brittle. The hardening requires very few hours. He had abandoned starch dressings, giving glue the preference. Being cheap, it is desirable for hospital use. Glue alone takes too long to dry. It is the lightest dressing we have for its strength.

Dr. Levis also called attention to a new article of lint, very cheap, being but eight cents a yard, or fifty cents a pound, imported lint being a dollar. It is made of different kinds and thicknesses, and with a covering of a sort of pervious material, which only requires moistening to render it ready for use.

Dr. Hodgen, of St. Louis, inquired whether the glue dressing was applicable to fractures of the thigh.

Dr. Levis stated that it had been used in other forms of fracture.

Dr. Hodgen wished to enter his protest against the doctrine that any other than fixed dressings in fractures were instruments of torture. Reduction cannot always be properly accomplished. In some fractures of the thigh, even when a fixed dressing is applied, it will move itself, without interference of patient or any one else. Results will necessarily be unfavorable in such cases. Gentlemen who think differently must have forgotten the laws of physics and anatomy, and that a part so long at rest will commence to atrophy. The treatment by the long splint and the perineal band is an abomination that should be discarded forever. He referred to different forms of fracture apparatus, giving his objections to the inclined planes; and expressed surprise that a man of such mechanical tact as Dr. Sayre did not employ suspension, and thus free his patient of pain without interfering with the circulation. He had rarely noticed the snap referred to by all authorities in the reduction of dislocations of the hip-joint.

Dr. Sayre said that Smith's anterior splint rarely put the limb in the precise position which was given it on the triple inclined plane, but the latter has the advantage that, if necessary, you can move your patient to a distance. After the apparatus was once fixed it was not intended to be moved, as some had suggested. The universal law for fracture is adjustment, fixation, and retention until union occurs, which will be by first intention of the bone in twelve to fourteen days. After that you can examine it every day. As Dr. Hodgen had said, there would be loss by shrinkage of the plaster-of-Paris; new plaster must be put on frequently, if necessary, and the slack taken in. Extension after adjustment is all wrong; it excites reflex irritation of the muscles, when you want quiet and rest.

Dr. Post stated that he was deputed by the Sanitary Commission at the close of the late war, to visit the military hospitals at Washington, particularly to learn the results of gunshot fractures of the thigh. He found that about half of the number had been treated by extension with weight and pulley; the others by a variety of methods. He was satisfied that the cases treated by N. R. Smith's apparatus, by extension by weight and pulley, was much superior to results obtained by any other method. The patients said that their sufferings were much less after application of the extending force. Suspension need not be made if the patient is perfectly comfortable without it. He had seen many excellent results at Bellevue and other hospitals, where the patient was carefully watched, under other kinds of treatment, as the plaster-of-Paris; but the latter was a dangerous remedy in the hands of the inexperienced, cases in illustration of which were cited by him.

Dr. Quimby maintained that we cannot get good results without extension and counter-extension.

Dr. Hodgen inquired why the patients at Bellevue were allowed to walk around the room in the plaster-of-Paris apparatus. Atrophy would not be prevented by such exercise when the limb was thus confined. Since the war he had treated his cases by suspension and extension with good results.

Dr. Gill, of Illinois, was of the opinion that greater attention should be paid to the measurements, in order to ascertain whether one kind of apparatus or another will give better results. He described an instrument made simply with a straight cross-piece with hinges, which would obviate mistakes.

Dr. Brother, of Illinois, urged that the apparatus

which confined the patient to bed with suspension and extension apparatus gives him more comfort and produces just as good results as any other.

On Thursday afternoon, Dr. Sayre introduced a little patient, just brought to his notice, of whose case his father, a physician, gave the history, one of Pott's disease resulting from accident. He had applied the apparatus recommended by Dr. Sayre without consulting him, but too loosely; and had, therefore, brought him on to see him here. Dr. Sayre again explained at length the method of application, measurement, etc., upon the patient.

After remarks by the Chairman as to the advantage of perfect rest involved in this mode of treatment, Dr. Brother, of Illinois, protested against the doctrine taught by Dr. Sayre, that shortening or deformity should not occur in fractures of the femur, as being contrary to the teachings of every surgical writer of the day. Suits for malpractice will be the result. He then enumerated the advantages of suspension and extension.

Dr. Quimby suggested the name of Dr. J. W. Thompson, of Kentucky, who had studied the subject of inheritance of syphilis, as a member of the committee which was to report next year, which, after discussion, was adopted. After some further explanatory remarks on his amputation of the foot, Dr. Quimby brought before the Section an operation for extraction of polypus of the uterus, by twisting the tumor, allowing it to remain *in situ* for a few days, to cause it almost to slough at the stump, and removing it with forceps without hemorrhage, the patient all the while being kept perfectly quiet. The plan is suggested when the polypus is within the uterus.

Dr. Dunlap had employed this method, but preferred the wire and écraseur, because of the risk of pyæmia. He described the manipulation required.

Dr. Quimby referred to the difficulty of this method when the tumor was large.

Dr. J. L. Atlee inquired why, in ordinary cases, the twisting suggested by Dr. Quimby should not be continued at once until the tumor was separated, and thus avoid risk of septicæmia. He cited an interesting case to show the advantage of pulling down the tumor with obstetric forceps far enough to have a thorough inspection of it, and then operating.

POLYPOUS TUMORS OF THE UTERUS.

Dr. McClurg referred to the facility with which even large polypous tumors could be twisted off.

Dr. Bell wished to know how we could tell that a fibrous tumor has a pedicle.

Dr. Atlee said they must have an attachment. First dilate the os with a sea-tangle tent, then a sponge tent, and ascertain the position of the fibroid; after which, if we give ergot, we may remove the polypus.

In reply to inquiry by Dr. Gill, as to amount of twisting required, Dr. Quimby said it was difficult to lay down any rules. A very few twists will arrest the circulation. There was less danger from septicæmia than from undue manipulation; and a fragment left behind after the use of the écraseur might produce septicæmia more easily than the whole mass would, if left in the cavity after twisting.

Dr. Reyburn, of Washington, thought it better to twist off the tumor at once, and leave a healthy granulating surface behind. He argued in favor of non-interference with stationary uterine intramural tumors.

Dr. Brother asked Dr. Quimby why he would not give another twist to separate it.

Dr. Quimby said the object was to prevent irritation and hemorrhage.

Dr. Dunlap said that if septicæmia occurred, it would be because of the presence of this large mass of gangrenous matter; there would not be enough pus to produce pyæmia. He agreed with Dr. Reyburn that non-progressive intramural tumors need not be disturbed. He cited cases showing the difficulty in some cases of applying the écraseur and wire. He was opposed to slow dilatation with tents.

Dr. Quimby said that the mass smelt as sweet as it did when making the examination. The point of constriction was the only situation at which suppuration could occur.

Dr. Waterman, of Indiana, thought this discussion belonged to the Section of Obstetrics; but the chairman said that, in his view, it was purely a question of surgical treatment.

Dr. W. L. Atlee never employed ligatures in the treatment of fibroids, but removed the latter at once with the knife, when they were accessible. He drew them down with the forceps, and enucleated them as he did ovarian tumors when adherent to the intestines. There is little danger of hemorrhage, if you have the proper applications, as the persulphate of iron, ready to tampon with. He would not hesitate to nick the mouth of the womb all around, if necessary, and then give ergot, bring down the mass and operate with the knife. The tampon of persulphate should remain three or four hours. Hemorrhage only occurs when the fibroid impinges on the hypertrophied mucous membrane, and could be arrested at once by passing the end of the bistoury into the cavity of the uterus, guided by the sound, turning the edge against the mucous surface, and bringing it out through the substance of the tumor. The vitality of the tumor destroyed, it is thrown off like an old placenta, and the mucous membrane will heal up. If septicæmia occurs, sulphurous acid is the best remedy, inhaled in the atmosphere of the room or given internally. He would not leave the tumor behind after twisting it, but remove it at once. He never meddled with intramural fibroids unless they were doing mischief.

Dr. Easley confirmed the views of Dr. Atlee as to the excellent antiseptic properties of sulphurous acid.

Dr. Post agreed generally with Dr. Atlee, and in regard to the danger of septicæmia from leaving the mass in the uterus. He differed with him in the view that the knife was always preferable to the ligature in the removal of parts; some vascular tumors and cutaneous diseases were certainly exceptions to such a sweeping rule.

Dr. Atlee stated that he only alluded to these fibroid tumors.

After remarks by Dr. Scott, of Ohio, on the conditions under which absorption might occur to produce septicæmia, the Section adjourned *sine die*.

NEW YORK ACADEMY OF MEDICINE.

Stated Meeting, June 15, 1876.

Dr. S. S. Purple, President, in the Chair.

The President announced the death of Dr. John O. Stone, one of the founders of the Academy, and appointed Drs. A. C. Post, O. White, and G. M. Smith as committee to present appropriate resolutions.

Dr. T. C. Finnell read a memorial upon the death of Dr. Cyrus Weeks, one of the oldest members of the

Academy, and presented a resolution, which was unanimously adopted.

Dr. Gouverneur M. Smith, from the Committee on Portraits, presented a written report, and acknowledged the receipt of a portrait of Dr. James Anderson, an Ex-President, presented by his son, Dr. J. H. Anderson.

Appropriate resolutions relating to the death of Dr. John O. Stone were read by Dr. A. C. Post, and unanimously adopted by the Academy.

ON CHOREA—ITS CAUSES AND ITS TREATMENT.

Dr. George T. Stevens, of Albany, N. Y., read an interesting paper upon the above subject, in which he announced a new theory with reference to the cause of what has heretofore remained a scientific mystery, notwithstanding the profound researches of medical inquiry. Dr. Stevens first gave a brief *résumé* of the opinions at present held by the profession concerning the pathology, etiology, prognosis and treatment of chorea, and then advanced the following proposition:

Chorea is a functional disturbance of the nervous system which may give rise to organic lesions, and which arises from irritation dependent upon anomalous refraction of the eye, and in a very large proportion of cases, to hypermetropia.

Dr. Stevens had studied this subject in a three-fold manner: 1. Clinically, where he had been led gradually and almost unconsciously to the conclusion embraced in the foregoing proposition; 2, by means of observations, with the view of testing the correctness of the theory; and, 3, as a reasonable and natural hypothesis.

At first the doctor regarded the association of error of refraction and chorea as a mere coincidence, but during the past two years he had regarded the coincidence as unfailing.

Dr. Stevens had collected thirty-three cases of chorea, and had found simple hypermetropia in twenty-four. Thirteen of the cases had been under his personal observation, clinically, and in no instance had proper convex glasses failed to afford relief to the choreic symptoms, and in several cases the relief had been prompt and complete. In the nine cases in which hypermetropia was not found, other optical errors were present. With regard to the reasonableness of the hypothesis that such an error of refraction could be the cause of so serious a nervous derangement, the doctor remarked that it would probably be less apparent to the general practitioner than to either the specialist in nervous diseases or the oculist. Allusion was made to the fact that almost every one was familiar with the aching eyes, the nausea, and the vertigo which might be produced by wearing glasses that disturbed the accommodation of the eye. Peripheral irritation, long continued at any part of the body, might give rise to serious nervous disturbance, and such cause Dr. Stevens regarded as abundantly potent to produce chorea. There was a constant state of confusion among the muscles of accommodation; an irrepressible conflict, which had given rise to a general nervous erethism, and then came measles, scarlatina, fright, or some other exciting cause, by which the nervous system was still further disturbed, and chorea was developed.

With reference to the embolic theory of chorea, the doctor remarked it was a well-known fact that sufficient irritation could be transmitted from one eye through the deep-seated origin of the third pair of nerves to produce destruction of the opposite eye; and was it unreasonable to suppose that degenerations and lesions might be induced at the origin of those nerves, in consequence of continued irritation and vexation at their extremities? Could not the lesions described by Hughlings Jackson, as occurring in chorea, be in that way satisfactorily explained?

In other words, peripheral irritation was regarded as the cause of chorea, and that irritation was located in the accommodating muscles of the eye.

The following proposition was submitted by Dr. Stevens, without argument:

Functional nervous diseases of all kinds are, beyond any and all other causes combined, dependent upon anomalous refraction of the eyes.

The paper being open for discussion, Dr. Noyes remarked that he had been much interested in the facts and observations brought forward by Dr. Stevens; although not prepared to give them either his dissent or approval. There were, undoubtedly, important disturbances of function dependent upon functional errors of sight; and Dr. Weir Mitchell, of Philadelphia, had called attention to certain cases of headache which found their true solution in ocular derangements. Any form of peripheral irritation in a susceptible person might give rise to some disorder of muscular coördination. Dr. Noyes related the history of a case of chorea which seemed difficult to explain by the theory advanced by Dr. Stevens. A patient had been suffering from chorea for some time, and was brought to him for examination concerning trouble referable to the eyes, when it was found that there was certainly no error of refraction, and only a slight amount of debility of the ocular muscles. To that debility the Doctor ascribed all the visional inconvenience and distress, and furthermore explained it on the ground of the general debility of the patient, feeling that there was no reason why want of proper power of coördination in the general muscular system could not at the same time exist in the ocular muscular system. A tonic course of treatment cured the patient completely. Dr. Noyes was also unable to understand how Dr. Stevens' theory would explain certain peculiar forms of chorea, such as hemi-chorea and the like. The crucial test, however, for the theory would be facts derived from the examination of a large number of cases, with special reference to the presence or absence of optical errors.

Dr. Detmold regarded the facts brought forward by Dr. Stevens as sufficient certainly to encourage further investigation, but he was unable to see how it could explain the following case. A child, when three days old, lost both eyes from a sloughing ophthalmia, but it had since had chorea. Of course it was an isolated case. Again, if the theory was correct, how was it that so many cases got well while under the care of the common physician, and that without the use of glasses, or any evidence of disturbance of the vision? The Doctor, however, did not feel prepared to express an opinion either for or against the theory.

Dr. E. C. Seguin remarked that he was pleased with the paper by Dr. Stevens, because it was based upon the arrangement of a number of well-observed facts in support of a definite proposition. The crucial test, as remarked by Dr. Noyes, was not in the reasoning upon the theory, but in the examination of a series of cases by oculists, and possibly by specialists on nervous diseases. Dr. Seguin, however, brought forward a number of possible objections to the application of the theory to chorea in general.

First. The small number of cases of chorea in proportion to the large number of cases of myopia and hypermetropia found in our public schools.

Second. Some of the sympathetic symptoms of errors of refraction were remarkable for their definiteness and duration. They were vertigo, headache of various forms, and nausea and those symptoms when dependent upon errors of refraction, were remarkably persistent; whereas the same symptoms in connection with chorea were very seldom observed.

Third. Chorea might be produced by a great variety of pathological conditions; possibly lesion of the corpus striatum, dyscrasia, various kinds of peripheral irritation, mental disturbances and irritation, fear probably being the most common; and one of the most apposite under this head was the chorea of pregnancy.

Dr. Seguin also mentioned the remarkable coincidence which had been noted between chorea and cardiac disease, a fact not alluded to in the paper. There was a large class of pathologists who believed that the solution of the choreic problem could there be found, and that lesions productive of chorea existed somewhere in the brain, and were brought out by the cardiac disease.

Fourth. The effect of treatment was opposed to the doctrine as applicable to chorea in general. If the theory were true, it would seem that any mode of treatment, except such as corrected the refraction, would fail to cure, but he believed that chorea was positively cured by the use of arsenic, ether to the spine, etc., and that the cure was effected so rapidly that the question in those cases certainly was definitely solved. Furthermore, those cases in which relapse occurred were just those in which cardiac disease could be distinctly made out, and in whom there was a constant source of supply for material which might give rise to minute emboli in the corpus striatum.

Dr. A. McL. Hamilton fully concurred in the remarks made by Dr. Seguin, and continued by saying that his attention had been called to hypermetropia and other eye symptoms in cases of chorea, and he had found that they were invariably secondary. Strabismus was a common associate of chorea, and no other eye trouble had he found in connection with his cases of that disease.

Dr. Stevens remarked, with regard to Dr. Noyes' case, that, although it formed an apparent exception, it was actually one of the cases which served to establish his theory. For, although no error of refraction was found, the precise condition present in hypermetropia was there, namely: unequal action between the muscles of convergence and the muscle of accommodation.

With regard to Dr. Detmold's case, it was a fact well known by pathologists that destructive ulceration of the cornea involved the ciliary nerves to such an extent that removal of the affected eye became necessary to save the one remaining unaffected. There was, therefore, a nervous irritation in the very region involved in the hypermetropic condition, and that irritation might have given rise to the subsequent chorea.

With reference to Dr. Hamilton's cases of chorea, in which strabismus was present, no better evidence was needed of the presence of hypermetropia, for strabismus was one of the symptoms of that condition.

With respect to the infrequent occurrence of chorea among hypermetropic and metropic children, if the theory be true, the same argument might be used against hypermetropia being a cause of strabismus, and yet it was acknowledged to be the great cause of strabismus. Concerning the accompanying cardiac trouble sometimes found in cases of chorea, Dr. Stevens stated he was not able, perhaps, to speak with authority upon that subject, but he could see no reason why it might not be the irregular supply of nerve force, causing irregular heart action, that gave rise to the cardiac disease. Certainly there were very many cases of chorea in which cardiac disease was not present.

Dr. Gouverneur M. Smith inquired of Dr. Stevens how he would explain those cases of chorea which were so rapidly cured—for example, by the use of arsenic?

Dr. Stevens replied that certain functional disturbances of a nervous character might be relieved by the use of arsenic, which imparted vigor to the general system; but it did not necessarily follow that the predisposing cause was also removed; and it did not prove but that, with the increased vigor imparted to the muscular system in general, there came vigor also to the ciliary muscle.

Dr. J. C. Peters believed that, while certain cases of chorea might, and very probably had been, explained by the theory advanced by Dr. Stevens, there were many other cases, the occurrence of which the theory hardly explained.

Upon motion made by Dr. Detmold, a vote of thanks was unanimously tendered to Dr. Stevens for his able and interesting paper.

The Academy then adjourned, to meet on the third Thursday of September.

NEW YORK MEDICAL JOURNAL ASSOCIATION.

Stated Meeting, June 16th, 1876.

Dr. Frank P. Foster, Vice-President, in the Chair.

Dr. E. Darwin Hudson read a paper

ON THE DIAGNOSTIC RELATIONS OF INDIGESTIONS,

by which was meant, not only what was more commonly embraced under the head of dyspepsia, but perversion of absorption and secretion, together with the morbid blood state which they created. Whether the valves of the heart became diseased, the arteries became degenerated, the brain the seat of softening, was regarded as a question of digestion and assimilation. The Doctor then brought forward the histories of cases illustrating the interest and importance of the symptomatic and sympathetic symptoms of indigestion in its various forms. The paper was discussed by Dr. O'Sullivan. The Association re-elected its old Board of Trustees and then adjourned.

Stated Meeting, June 23, 1876.

Dr. C. T. Poore read a report upon

ORTHOPÆDIC SURGERY AND ALLIED SUBJECTS,

in which he brought forward the literature upon the subject for the year 1875. In speaking of the case reported by Dr. Lewis A. Sayre, in which section of the latissimus dorsi muscle was divided for the purpose of assisting in the correction of lateral curvature, the doctor said it was no new operation, but that long ago muscles had been divided by Guérin, Malgaigne, and others, to rectify lateral curvature of the spine, but that the operation did not afford satisfactory results, and had been abandoned by English surgeons altogether. With regard to the use of the plaster-of-Paris jacket in the treatment of Pott's disease, Dr. Poore claimed that it was first used by Dr. Bryan in Bellevue Hospital prior to the date at which Dr. Sayre used it for the same purpose. The Association then adjourned.

Correspondence.

SUMMER RESORTS AND METROPOLITAN PRACTITIONERS.

To the Editor of The Medical Record.

Saratoga Springs, July 20, 1876.

Dear Sir:—I have been much interested in reading some extracts from the address of Dr. Sims, delivered before the American Medical Association at its late meeting, June 6th. Some points in this address have already been referred to in the columns of your valuable journal; and I solicit the favor of a space in the Record for some comments pertinent to the extracts I have read, and suggested by our professional surroundings in this place.

The portion of the address relating to the Code of Ethics is suggestive, and opens to view some points worthy of professional consideration and digestion. But that to which I desire to allude more particularly, is the portion where Dr. Sims says: "A gentleman high in the ranks of the profession, holding a distinguished position among us, wishing to change his place of residence, writes to me to know how he can notify the world of his intention, without violating the Code of Ethics; and he and a friend of his, a well-known stickler for the inviolability of the Code, hold grave consultations over the easiest way of getting round its provisions without a flagrant violation of them. These are honest and honorable men, and would not do anything wrong. But they feel that they are hampered by rules that are unjust and oppressive." Pardon me if I ask you, "Is the Code of Ethics up to the requirements of the times, when it compels honorable men to do dishonorable things to promote an honest action?"

The instance here mentioned, and the sentiment expressed, seem to bear so close a relation to circumstances transpiring in our midst, that I venture to state the coincidence, and express my regret that gentlemen are so hampered by the Code, and my surprise that we must be "dishonorable" while we are "honest."

To the members of the medical profession residing in this village, the question raised here has a special interest. The fact is well known to all that *the season* at Saratoga Springs brings hither a large number of visitors from all parts of the country, and during the summer months our population is almost doubled. With this increase of residents there is a proportionate increase in the demand for professional services; and recognizing this fact, it has of late years become the custom among certain gentlemen of the profession, residents of cities, where they have large and remunerative practices, to flock hither during the summer months, locate themselves at one of our large hotels, and secure all the professional business they can. They do not come for rest and relaxation from professional labors at home, but come with an eye to business, and lose no opportunity to publish their presence in our midst. Some—and I speak from actual knowledge—have this season applied to the proprietors of some of our larger hotels for the privilege of putting up *the shingle* in the office of the hotel as a special announcement of their presence and desire for patronage—a privilege, however, which was not granted. Another heralds his presence here by circulars and announcements in the journals, of the date of his coming and departure, and the case bears a striking resemblance to the instance alluded to by Dr. Sims, and quoted above. Others are here, making no announcement of their presence, but, as one remarked, desiring "to do business enough to pay expenses."

The regular profession of this place, residents of the village the year round, have looked with wondering eye at the practices resorted to by some of these gentlemen of high standing in the profession; and we ask in all candor, is this the part of professional courtesy, and are these gentlemen within the Code, or are they in that sad dilemma raised by "the requirements of the times," which "compels honorable men to do dishonorable things to promote an honest action?" We reside here not for the sake of local business alone, for the loaf is not large in proportion to our numbers, but with the view of meeting the demands made upon us by the cosmopolitan character of our summer population. This is the remunerative portion of our business, and we labor to fit ourselves for its requirements; and though looked upon by some as only types of the country doctor, profess to be not far behind our city brethren in the literature and journalism of our profession. Do the requirements of these gentlemen compel them to do this? Does the nature of this increase of our summer population deprive us, who labor in our professional walk here, of any claim upon it as a source of professional business? We have identified ourselves with this village in all its interests; we look to the hygienic and sanitary condition of our surroundings, that we may have no source of disease in our midst, and we bear our share of the burden of taxation, for all the means adopted for the improvement of our village; but, as these gentlemen assert by act, if not by word, you have no right, title, or claim to the professional business the character of your village, as a watering-place, may bring within your borders.

The Code of medical Ethics is not up to the requirements of these gentlemen, and they hold no grave consultation over the easiest way of getting round its provisions. I do not care to particularize; but pardon me for making the following query: Will the Code sustain any member of the profession, who, having ascertained that a gentleman lies ill in a neighboring hotel, under the care of one of our resident physicians, in sending to the patient his professional card, announcing his presence in the village, and where he can be found? Such an instance occurred here not many days ago.

We cannot consider these gentlemen as high-priests of the Code, for they do not hesitate to shock the moral sense of the profession by their irreverent treatment of it. They are sincere, if not honorable, in their purpose; and though the written Code may be far behind their requirements, there is an unwritten Code which appeals to the honor and honesty of every one who would consider himself a gentleman in the profession, of which they are equally regardless.

Yours respectfully,

M. C. E.

[Our correspondent takes a sensible view of the situation, and has a just cause for complaint.—Ed.]

THE MICHIGAN STATE MEDICAL SOCIETY AND HOMŒOPATHY.

To the Editor of The Medical Record.

Albion, Mich., July 19, 1876.

Sir:—Will you have the kindness to allow me a few words of comment upon a communication, printed in the Record of July 15, from Dr. Maclean, Professor of Surgery in the University of Michigan.

He wrote to correct what he considered to be a mistake in your report of the proceedings of the National Association, but has succeeded in making the only mistake in the case. I am from Michigan, was a delegate to the Association, and was present when Dr. Frothingham preferred his last charges.

The facts in the case are just these: In the first place, charges were preferred against the Michigan State Society and its delegates, by a gentleman of the Faculty at Ann Arbor. At first the delegates of the Michigan State Society were not allowed to register. The charges came at once before the Committee on Ethics, etc. This committee dismissed these charges and admitted the Michigan Delegates, Dr. Benham bringing his report to this effect while Dr. Atkinson was calling the roll. As soon as the applause was quieted after the reading of this report, Dr. Frothingham arose and preferred charges against Drs. Foster, Pratt, and G. K. Johnson only, and not against the Michigan State Society or the whole Michigan delegation, as Dr. Maclean states in his letter above referred to. It is understood that these charges are to the effect that these two gentlemen are guilty of a breach of ethics, and of unprofessional conduct, in that they once formed a part of a special committee appointed by the Michigan State Society, on Medical Legislation, and that they sat in joint committee with practitioners of both the Homœopathic and Eclectic schools, and that they, in connection with the whole joint committee, recommended to the State Legislature a bill to provide for a State Registration Board, which should be composed proportionately of Regular, Eclectic, and Homœopathic physicians. Of course if these gentlemen (Drs. Pratt and Johnson) are reprehensible, the State Society are equally so. Every intelligent man knows that there is a vast difference between the matter of registration of physicians and that of their education and graduation by a Medical Faculty.

But not to argue this point, permit me to say, that if our State Society or these gentlemen in particular, are in the wrong, we wish to know, and are willing and anxious to be set right.

Dr. Maclean says that interested and unscrupulous persons have endeavored to persuade the profession of the land that we, of this University Faculty, have been, and are, in the position of aiders and abettors in the graduation of homœopathic students.

Permit me to say, Mr. Editor, that it is the opinion of the profession of this State, that Dr. Maclean states the truth exactly, except in so far as he says that interested and unscrupulous persons have endeavored to "persuade" to this opinion. The profession have needed no persuasion in this matter. It is plain to all that the moment Dr. Maclean or Dr. Frothingham admitted to his lecture-room, or examined at the close of the lecture season, one who was known to be a registered homœopathic student, that "they of the University Faculty" were guilty of aiding and abetting the teaching of homœopathic students, and therefore, of their graduation. This talk of "standing in the breach, and preventing the country from being flooded with homœopathic students" may sound well to non-professional readers, but to the physicians of this State it is weak.

What the Michigan State Society desire above all else, is a "calm, full, and impartial investigation of these matters." And they propose to abide by the decision, whatever it may be.

In conclusion, let me say that the profession of this State have no ill-will towards the Medical Department of the University. Too many of them attended lectures and graduated there. We wish it well, and pray that it may soon shake off this seeming, at least, connection with sectarian medicine. It had been just as easy to have had the homœopathic department entirely separate and distinct from the regular school, and, indeed, such was contemplated by the State Legislature. It was the management of the regents that hybridized the two schools, that money might thus be saved to help a non-paying department of the University. But it now seems that the regents are gradually receding from their first action. Within a week two more homœopathic professors have been appointed at Ann Arbor, that of Obstetrics and Surgery. Let two more professors be appointed, so that the two schools may be as separate in *fact* as they are in *name*, and *then* all cause of complaint and misunderstanding will be gone. To satisfy all classes of people, and carry out the theory of "fair play" to its legitimate conclusion, we must ultimately see established at Ann Arbor, as a part of the University, a department of Eclectic (so-called) medicine, of Hydropathic, of Clairvoyant, and the Seventh-son system of medicine. All the different sectarian systems must at last be represented. The University may be thus lowered in the estimation of scientific men, and yet we shall find no fault.

One word more. As a matter of good taste, it would have been far better for the medical "University Faculty" to have maintained a dignified silence upon this "vexed question," and left the active championship of this "doubtful cause" to other gentlemen, if there are such in the profession, who sympathize with them in this matter.

Yours very truly,

JOHN P. STODDARD.

"PATENTED" VERSUS "PROPRIETARY."

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—Permit me, agreeable to your judicious invitation in the MEDICAL RECORD, to set down a few facts in regard to patents in medicine. Medical, and also pharmaceutical writers, speak of "patented articles" and "proprietary articles" in one strain, and rate them in one and the same category of vile and secret nostrums and quack medicines. This is evidently a confusion, out of want of knowledge of facts; because:

"*Proprietary Remedies.*"	"*Patented Remedies.*"
1. Are innumerable.	1. Only a few in existence.
2. Formulæ are kept secret.	2. Formulæ published; therefore not secret.
3. Generally they are good for everything.	3. They are of some therapeutic value.

These differences and distinctions are so positive and obvious, that the profession should not ignore them, and should certainly be disposed to make a due discrimination between them.

Most respectfully yours truly,

JULIUS FEHR, M.D.

HOBOKEN, N. J., July 28th, 1876.

PRELIMINARY MEDICAL EDUCATION.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—Harvard College has raised its standard of admission, and after September, 1877, will require of applicants a degree in letters or science from a recognized college or scientific school; or, in lieu thereof, a fair reading knowledge of Latin, French, or German; a respectable orthography, and a decent conception of English grammar.

Little enough this; but where is there a medical school, from Maine to Texas, that requires even so much of those that yearly swarm about their doors? Scandalous as it may seem, it will be allowed that I do not exaggerate in the assertion, that the majority of those who enter our medical schools from year to year would be unable to write and spell correctly ten consecutive lines of an ordinary letter. They will be ignorant of the proper place for a capital or punctuation-mark. With the expectation of dealing all their lives with Latin words and phrases, they will be unable to distinguish the nominative from the genitive case. They will be unable to define even the meaning of the phrases, 'natural, intellectual, and moral philosophy.' The chances are, that they will go through their whole professional career, if they pursue their object to the end, without having mastered more than the rudiments of medical science. Still speaking generally, a more ignorant set of men gather in no halls of learning than gape and titter in the amphitheatres of American Medical Colleges. From the plough and workshop, without any preliminaries, they have entered into studies that, from their very nature, require a firm foundation of previous intellectual training. That the necessary habits of systematic thought and study will be acquired, is, in most cases, out of the question. The wide and thorough general culture demanded of physicians, becomes, in their hands, narrowed down to the mere watching of symptoms and dispensing of drugs. Skilled perhaps in technicalities, standing well in the estimation of the ignorant, before men of intelligence they bring the whole profession into discredit. This irruption of illiterate men into what is claimed to be a learned and liberal calling, cannot be too much deprecated. Its best interests as a body, as well as those of its individual members, demand the highest talent and the most generous culture.

The physician who has started into the world with an inadequate mental culture, may attain eminence and an extensive and lucrative practice. So far as business and money-making is concerned, he may be entirely successful. He has a "sound judgment," general force and weight of character, a faculty of pleasing, persuading, and satisfying; fidelity, moral excellence, affinity, acuteness. He is "the fashion." The Great Public, wholly incapable of judging the relative merits of medical men, accepts him; and sees in his failures, not the insufficiency of the individual, but that of the whole profession.

The physician's high responsibilities are not alone confined to the weary couch of his patient, but extend to every walk and occupation in life. The broad scope of his intellectual culture should enable him to be the mentor of statesmen, the clergy, and educational corporations, whose opinion can command their respectful attention. Men pay little regard to the advice of those whom they regard as their intellectual inferiors. To obtain influence over the minds of others we must be able to cope with the best of them, and challenge their respect and confidence.

The question is asked, "Of what use is the Latin language as a preparation for the study of medicine?" Well, in the first place, a fair knowledge of Latin is pretty good evidence of one's general schooling. The possessor of a reading knowledge of Latin is inferentially tolerably well trained otherwise. The Latin language is the philological basis of scientific literature, and in fact of all literature. Many causes have contributed to this: the circumstance of its being a dead language (and thus not subject to change); its ready adaptability, its long use by the church of Rome and the priesthood, who were for centuries the possessors and sole guardians of science and literature. Those who fail to perceive the benefit to be derived from a knowledge of Latin, fancy they can see a very practical advantage in a knowledge of French and German, not as an intellect-opener—if I may be allowed the expression—but as something they can use in professional intercourse. As well claim the same advantage from a knowledge of music. I must assert that to an English-speaking person a thorough knowledge of English grammar is far preferable.

Harvard College requires and has required a three years' course; and now those seeking a diploma are obliged to pass a most searching examination in every branch of study. Contrary to what might be expected, there seems to be no falling off in the number of students applying for admission; and if other medical institutions would follow her good example in thus raising the standard of admission and graduation, they also would probably lose nothing, while the profession and the world at large would certainly be the better therefrom.

B. Pillsbury, M.D.,
Middletown, N. Y.

ARMY RANK.

To the Editor of The Medical Record.

Sir:—The views expressed by Dr. Rolleston before the Medical Council were intended to show that the *status* of English medical officers (like that of our own naval medical men) is not *de facto*, as in the army of the United States. In our army, the military title is given to all medical officers in their commissions, and they use it, and are addressed by it, socially and officially. The military title is indispensable to military and naval medical men, as it distinctly defines their military position in the services, and is the *only one* that is or will be acknowledged by the line or combatant branch. The title of "Surgeon-General," "Surgeon-Major," "Medical Inspector," etc., are not absolutely distinctive of rank or duty, and are distasteful to English medical officers, who see no reason why a *military* title should be given to *paymasters* and refused to them.

We have the same trouble in our navy, with its absurd "*relative*," or assimilated rank, which for fifty years has been the cause of all the heart-burnings of the staff.

The high rank accorded to English military and naval officers is like that of our navy—"*relative*," or assimilated—which is declared by the combatant branch to be a "*rank-humbug*."

Bogus.

AMERICAN MEDICAL ASSOCIATION.

To the Editor of The Medical Record.

Sir:—Referring to the remarks of your Philadelphia correspondent on the meeting of the American Medical Association, in your issue of the 24th ult., I can endorse his statement as to the excellent acoustic properties of "Horticultural Hall," with a large audience, such as Tyndall secured; but with the small number of delegates present on the 6th of June, and the very bad order maintained on that occasion, it was *impossible* to hear what was going on. I have been present at a good many medical meetings at home and abroad, and I am sorry to say that I never was at one where there was less dignity and decorum than at Philadelphia; in fact, from the time of registration to the

hour of adjournment, the whole affair was more like a political meeting than a dignified professional gathering.

The wholesale manufacture of delegates into permanent members—merely because they are State delegates—appears to be wrong; in this way the State societies really make their delegates members of the American Medical Association; whereas, if we are to consider such membership an *honor*, the Association should make its own selection from the leading medical men of the country.

'Απλοτης.

Reviews and Notices of Books.

Cyclopædia of the Practice of Medicine. Edited by Dr. H. von Ziemssen. Vol. IV. *Diseases of the Respiratory Organs.* By Dr. Fraenkel, of Berlin; Prof. von Ziemssen, of Munich; Prof. Steiner, of Prague; Dr. Riegel, of Cologne; and Dr. Frantzel, of Berlin. Albert H. Buck, M.D., New York, Editor of American Edition. 8vo, pp. 805. New York: William Wood & Co. 1876.

The volume before us, although but fourth in number, is the most recent one of the series issued in this country. Evidently, therefore, its appearance in Germany must have been considerably delayed. On turning over its many pages, and observing the number and character of the subjects therein discussed, one cannot but regret that some of the authors had not improved a part of their time in abbreviating and condensing their papers. The only two articles not deserving this criticism are that of Fraenkel on Diseases of the Nose, which is thoroughly practical; and that of Steiner on Croup, which is short and clear cut, and, being admirably translated, is the most readable essay in the book.

The first ninety-eight pages of this volume are occupied with the General Diagnosis of Diseases of the Nose, Pharynx, and Larynx, by Dr. Fraenkel. The subject is ably handled and the ground amply covered, more so, in fact, than in many works devoted to the specialties herein considered. The different methods of illumination, the combinations of concave mirrors and lenses, as well as all the photometric measurements and mathematics of optics pertaining thereto, are discussed at considerable length, while still the author gives to the discussion the practical stamp of the clinician.

The second section, on Diseases of the Nose, also by Dr. Fraenkel, covers eighty-two pages, and will interest the general practitioner, as furnishing much valuable information on a class of cases often met in practice, and with regard to which our general treatises are almost silent. It is true that Fraenkel does not solve the problem of how to cure a "cold in the head," but he does give us some fixed points on the subject of Purulent Nasal Catarrh, as well as the more common Chronic Catarrh, or Ozæna. In this connection we are informed that acute rhinitis *may* pass into the chronic form, "and yet, in the vast majority of cases, this only takes place in persons suffering under a dyscrasia,"—especially under the effects of scrofula or syphilis. Nothing new is advanced in the way of treatment, but the author urges the importance of physicians no longer neglecting or making light of cases of sub-acute or chronic nasal catarrh in children. Considerable space is given to the consideration of Epistaxis, while abscesses, ulcerations, tumors, foreign bodies, and parasites of the nasal cavity are more briefly disposed of.

Prof. von Ziemssen himself furnishes the introduction to Diseases of the Larynx, together with brief sections on Anæmia, Hyperæmia, Hemorrhage, Abnormal Color, and the Catarrhal Inflammations of the Laryngeal Mucous Membrane. The acute and chronic inflammations of the larynx is the only part of this that is of much interest. The distinction between acute laryngitis, in the form of pseudo-croup in children, and true croup, is made prominent. The writer also insists that every laryngeal affection, even the most trifling, should be followed up laryngoscopically. The treatment of chronic laryngitis, besides the avoidance of its causes, is mainly local, by inhalations of tannin, nitrate of silver, etc.

Prof. Steiner, of Prague, is already favorably known to the English reading medical public by his Compendium of Children's Diseases, a translation of which has been published in England and in this country. His article on Croup, like all that he writes, is short, clear, and practical, and is of special interest just now, when the question of the identity of croup and diphtheria is attracting renewed attention.

Apropos of this discussion, we are told that "the attempt to distinguish croup and diphtheria as two entirely distinct diseases has been unsuccessful, both from an anatomical and a clinical standpoint; indeed there are many good reasons for supposing that these two affections are only varieties and modifications of one and the same process." And yet a little later he says: "Another secondary form of croup, and one which is justly to be feared, is that which often accompanies epidemic diphtheria." It will be seen, on reflection, that the two statements are not necessarily contradictory of each other.

Steiner opposes the view of Niemeyer and others that dyspnœa, in croup, is caused also and mainly by paralysis of the laryngeal muscles. Croupous tracheo-bronchitis is mentioned as one of the most frequent and dangerous complications of the laryngeal disease. In cases that progress but slowly this may not arise till late, and when tracheotomy has been performed the author has often satisfied himself that there were no signs of bronchitis until two or three days after the operation.

In speaking of the histology of the croupous exudation, he agrees with E. Wagner that "there is no sharp dividing line between diphtheria and croup," but does not adhere to the rest of Wagner's views as to the production, in both of these affections, of a network resulting from a peculiar metamorphosis of epithelial cells. On the other hand, he considers that the views of Oertel, Klebs, Laycock, Wade, and others, who believe they have discovered the nature of the croupous diphtheritic exudation in the generation of fungi, to be equally untenable.

In the way of *treatment*, early and persistent application of milder remedies is especially advocated. Frequent gargling, or pencilling the throat with equal parts of lime water and distilled water, or with a solution of chlorate of potassa, twelve to sixteen grains to the ounce for children, and a drachm to the ounce for adults, is advised. Where this is impracticable or without result, touching with lunar caustic, or with a strong solution (two drachms to the ounce) of nitrate of silver, may be tried. For local application the author also mentions chromic acid, tincture of iodine, hydrochloric and lactic acids, sublimed sulphur, and chloride of iron, but has found

none so efficacious as those first mentioned, especially lime water. He is opposed to the use of calomel; considers emetics to be of value only by their mechanical effect, and advocates early tracheotomy. In performing this operation, for croup, he fears the use of chloroform. As before stated, Prof. Steiner's essay on Croup is, in our opinion, the best thing in the book, and is an interesting and most valuable contribution to the literature of this subject.

The remaining five-eighths of the volume (500 pages) are about equally divided between Dr. Riegel, of Cologne, and Dr. Fraentzel, of Berlin, the former writing on Diseases of the Trachea and Bronchi, and the latter on Diseases of the Pleura. They have neither of them, as yet, acquired the gift of brevity.

In Dr. Riegel's prefatory remarks may be found a valuable résumé of what is known with regard to the origin of cough, or the comparative susceptibility to irritants of different parts of the respiratory apparatus. The question of the influence of climate on the production of bronchial catarrh is ably handled, nor is the etiological significance of dust inhalation lost sight of. The sections devoted to the diagnosis of different forms of bronchitis are full and very satisfactory, amply repaying their careful study. In view of the rarity of their occurrence and the small amount of positive information given thereon, far too much space, in our opinion, is devoted to such subjects as Croupous Bronchitis, Stenosis of the Trachea and Bronchi, and Foreign Bodies in the Trachea. Those practitioners whose lives have been made a burden by the care of asthmatic patients whom they could neither cure nor kill will be interested in the able and exhaustive section on the Etiology and Pathogenesis of Bronchial Asthma. Unhappily nothing new is advanced in the way of treatment.

Dr. Fraentzel's paper on Diseases of the Pleura is long and heavy. The anatomical part of it is good.

Then follow forty-five pages on Symptomatology, and forty-eight pages on Treatment. If any future President of the American Medical Association is tempted again to accuse the Germans of being *nihilists* let him first read these forty-eight page s of treatment.

Venesection—6½ to 9½ ounces—is only recommended where there is very high fever and rapidly increasing effusion. Eight to twelve wet cups are better, or, in children, leeches. Digitalis and calomel, in grain doses, are given till the pulse is lowered or salivation forbids. Mercurial inunction is advised, also dry cupping, blistering, sinapisms, flying blisters, and iodine paint. The use of cold or of large doses of quinine is not recommended. Excellent results are claimed for drastic cathartics when the inflammation has reached its height. The author is decidedly in favor of puncturing the thorax and removing fluids by aspiration, whenever they fail to be absorbed or are doing serious harm. He gives due credit to Dr. Bowditch, of Boston, for having revived and introduced the operation of paracentesis.

On the whole, the fourth volume of the Cyclopædia is a valuable and interesting one; and if we are a little annoyed at the prolixity of some of its contributors, we must remember that all the articles in such a work as this cannot come from the master pen of a Liebermeister or a Juergensen.

The Mortuary Record of The Mutual Life Insurance Company of New York.

The combined mortuary reports of the Medical and Actuarial bureaus of the Mutual Life Insurance Company of New York, have been submitted to us through the kindness of the Medical Director of the above-named Company.

The volume is elegantly gotten up on tinted paper, full morocco binding, and is beautifully illustrated with elaborate colored tables and diagrams.

The experience which it sets forth is derived from a careful study of all the records of the Company, from its inception to the beginning of 1874, more than thirty years.

During that time the Company has been exposed to loss on 101,967 lives of different individuals, who have lived as members of the Company, a duration of time aggregating 578,112¼ years.

Out of this vast army of insured, 5385 deaths have occurred—something over five per cent.—a most reasonable mortality certainly. We are somewhat surprised, however, to see the large percentage of deaths that has occurred among those who were only on their first year of insurance—over ten per cent. of the losses thus happening. This, it seems to us, is a very large percentage; and reasoning from it, we must conclude that the average low mortality of the Company is due, *not only* to the care exercised in the selection of risks, but also to a combination of many favoring circumstances. Among the causes which are charged with these early deaths, "cancer and alcoholism" show a larger percentage in the first year than in several subsequent years. We can understand how this might be the case with the latter of the two causes—alcoholism—as many a *magnificent wreck* from drink can, by a little *fixing up*, be made to still present an *appearance* of even *robustness*; but we cannot see how it could be so with cancer; nevertheless, there it stands as a *fact*, and as such the report honestly states it. In the case of consumption, the value of medical selection is apparent, as the percentage of deaths from this cause during the first year is much smaller than in the subsequent years, when the advantages of selection pass naturally and rapidly away.

The value of good medical selection is also very well illustrated in "kidney diseases," including Bright's disease, where the percentage of deaths during the earlier years is very small indeed, being only 1.87 per cent. for the first year; whereas, further on, it rises to 6.57 per cent. Of suicides, on the other hand, out of the 59 instances reported, 13 occurred during the first year of insurance—over 22 per cent.—showing that to the average medical observer this "coming event," at least, "casts but little shadow before."

Of the 38 deaths from small-pox, half occurred during the recent epidemic, teaching very clearly, we think, the necessity of a better appreciation of the preventive effects of revaccination among the people at large.

In speaking of phthisis, the medical director calls attention to the fact, that the disease is *not* one which is *confined* to the *younger periods* of life; though it is generally so considered, not only by the laity, but by physicians. The experience of that Company shows that, while 525 deaths occurred from phthisis in individuals *under* 40 years of age, there were also about 400 deaths from the same cause in those who had passed 40 years. This is a point for Life Insurance underwriters to consider carefully.

Old age comes in for but a small showing, only 13 deaths from this cause being cited. Every decade hereafter will, no doubt, rapidly swell the numbers of this class.

As to the influences of nationality on the different causes of death, we have some interesting facts: for instance, *strong drink* showed itself *strongest* among

the English and Irish, and *weakest* among the phlegmatic and lager-loving Teutons.

Scotchmen seem most easily to fall victims to apoplexy and diseases of the nervous system, while the Irish fight most shy of them.

Scotchmen are also most liable to diseases of the kidneys (has oatmeal anything to do with it, we wonder?); but, however that may be, the Scotch and Irish *know better than to commit suicide*, for *not one* case comes from among them.

The Irish contribute the largest number to consumption; and their neighbors, the English, the least; while diseases of the circulatory system and accidents are equally distributed to all nationalities. As between foreign and native-born subjects, the foreign show an excess of ten per cent. over natives in deaths from cancerous disease.

LECTURES ON SYPHILIS AND ON SOME FORMS OF LOCAL DISEASE AFFECTING PRINCIPALLY THE ORGANS OF GENERATION. By HENRY LEE, Professor of Surgery in the Royal College of Surgeons of England. Philadelphia: H. C. Lea, 1875.

THESE lectures are, like all the writings of this author, disappointing. In reading this work, one is forced to the conviction that its author is not clear and precise as to many of his views of syphilis. Indeed, if the whole scope of these lectures is considered, the question forcibly arises, are they such as one could expect from the professor of surgery in the Royal College of Surgeons of England, and particularly are they worthy of delivery before such a learned body as the Hunterian Society? Both of these questions must be answered decidedly in the negative. It is certain that, had a man of less fame or a previously unknown author published these lectures, they would have, on account of their lack of grasp of the subject and of its inadequate treatment, consigned him to a low rank in literature. The author labors to call attention, as he says, to certain doctrines of Hunter, which he thinks deserve more prominence than they have heretofore received; but he has so far mixed matters that we have to return to our recollections of Hunter, to know which is his view and which that of Lee. The chapter on blood inoculation is a long and labored one, and in the end does not bring the question out in a clear and practical manner. We find in this work, as in all that Lee writes, the term adhesive inflammation for what is really cell-infiltration. Certainly in this late day, the proliferative processes of syphilis being so well understood, should not be thus called. Again, in describing syphilitic papules we find the author still uses that bad term syphilitic lichen, which for various reasons is inappropriate and unscientific. Still further, the author indulges in new and unnecessary names, as we find that he terms the inguinal glands, when syphilitic, amygdaloid, simply because they in, syphilitic persons, sometimes feel like almonds under the skin. We shall stop here, though many other minor faults are observed. There are, however, certain good points in the work; the remarks on syphilization and on the inoculation of various morbid discharges are evidently based on extended and careful study. No less interesting are the portions relating to the treatment of syphilis, in which, as of old, the author advocates the mercurial vapor bath, and comes out as a strong advocate of the use of mercury in syphilis. It must be confessed, however, that these good points are so few and unoriginal that they do not by any means counterbalance the shortcomings, both general and special, of the work. To a person who has already studied syphilis, the work will be a disappointment; and those who commence its study would do well to thoroughly avoid the book, as it inculcates such errors as would materially embarrass future study and observation.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from July 30th to August 5th, 1876.

BY S. O. 69, A. G. O. July 26, 1876, the following promotions and appointments in the Medical Department are made:—

PROMOTIONS.

To be Surgeon with the rank of Major: J. J. Woodward, Wm. H. Forwood, Ely McClellan, S. A. Storrow, W. D. Wolverton, A. Hartsuff, C. R. Greenleaf, J. V. D. Middleton, J. H. Janeway, H. R. Tilton, S. M. Horton, J. C. G. Happersett.

APPOINTMENTS.

To be Surgeon with the rank of Colonel: Robt. Murray, Chas. Sutherland, J. J. B. Wright, J. M. Cuyler.

To be Assistant Medical Purveyor with the rank of Lieut.-Colonel: Chas. McCormick, C. H. Laub.

To be Surgeon with the rank of Lieut.-Colonel: Wm. J. Sloan, W. S. King, Jas. Simons, C. C. Keeney, J. F. Head, L. A. Edwards, J. F. Hammond, E. J. Baily.

ROSE, G. S., Asst. Surgeon. Granted leave of absence for one month. S. O. 146, Mil. Division of the Atlantic, Aug. 1, 1876.

SEMIG, B. G., Asst. Surgeon. Leave of absence further extended one month. S. O. 153, A. G. O., July 28, 1876.

BEALL, GEO. T., Medical Storekeeper. Granted leave of absence for one month. S. O. 154, A. G. O., July 29, 1876.

Medical Items and News.

CONTAGIOUS DISEASES.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending August 5, 1876.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.
July 29.....	0	12	8	2	6	36	2
Aug. 5.....	0	4	7	2	4	20	1

RESTRAINT FOR CHRONIC INSANE.—Dr. A. M. Shew, Superintendent of the Connecticut Hospital for the Insane, in his Tenth Annual Report, says:—"Admitting the usefulness of restraint in certain cases, I desire to protest against the tendency to use it in ordinary cases of chronic insanity where employment, diversion, and watching would obviate the necessity for it. In this respect we have made great progress during the past year. On the first of November last, with a

population of two hundred and twenty-five male patients, only two were subjected to any form of mechanical restraint; one had his hands in a leather muff to prevent the removal of bandages from his leg; the other wore a camisole waist a part of the time to keep him from destroying his clothing. During the past three months these two men have been without restraint, and we have actually conducted the hospital on the male side on the non-restraint plan. I am under obligations to the officers and attendants who have taken so much pains to further efforts in this direction. Much of its success depends upon the character of the attendants having immediate charge of the wards. Kindness, regularity, and watchful attention are efficient qualities in this direction. The great want in every hospital is occupation; patients who are in suitable condition to do so go out with a sense of relief to farm work, to the kitchen, laundry or sewing room, and regard the change as diversion. The object in setting a patient to work is not that he may repay cost of treatment, but it is to aid him in casting aside fancies and in returning to healthy feelings and thoughts."

The Origin of Evil.—How often are the most important truths brought to light from sources the least expected. For ages the scientists, philosophers, and theologians have been seeking to discover the origin of "evil," otherwise the "devil," without coming to any satisfactory conclusion, when, lo! his sable majesty's nativity has been suddenly brought to light by an obscure and hitherto almost unknown tribe of savages, inhabiting a cold and almost inaccessible region.

The London *National Reformer* says:

"It is stated that Terra del Fuego has been traversed by Lieut. Masters, R.N., who has discovered that the natives believe in devils, and that they are the departed spirits of members of the medical profession. The main object of their religious ceremony is to keep these devils at a distance from them.

Classification of Amputations for Injury.—Prof. Verneuil complains of the confusion that exists among surgical authorities with regard to the classification of amputations for injury, according to the time when the operation is performed. Most surgeons recognize only two divisions, viz.: primary or immediate, and secondary or consecutive; but many make three periods. The Professor thinks that the more natural and satisfactory division is into three periods, and he proposes that these periods should be denominated the antepyretic, the intrapyretic, and the metapyretic. The operation in the second period is very dangerous, and should be put off as long as possible, and only performed when the fever is declining. The metapyretic period, or in other words the period of suppuration, begins with the subsidence of the fever, and may last for months or years.

Castor-Oil.—This nauseous drug can be easily taken, when administered in the following way: The glass should be first rinsed with moderately hot water, and then two drachms of hot water, one ounce of castor-oil and one drachm of peppermint water, put in in the order mentioned. This is easily swallowed, and leaves hardly any taste of the oil in the mouth.

Morphia in Sea-Sickness.—Dr. Dillard recommends subcutaneous injections of morphia in the epigastric region for this affection. He used the remedy in two cases, and in both the distressing nausea and other symptoms were relieved in about fifteen minutes, and did not recur. The dose used was five minims of Magendie's solution.

Poisoned Meat.—Prof. Bouchardat, of Paris, recently analyzed the yellow coloring of the cover of a ham, imported from Cincinnati, and found it composed of chromate of lead, a deadly poison.

Hydrophobia.—A case of rabies is reported by the *Veterinary Journal* (July) cured by the hypodermic injection of "less than half a grain of the woorara."

A Button thrown up two Years after being Swallowed.—Dr. Roth related at the Medical Society of Strasburg, the case of a child, three years old, who vomited a button two years after it had been swallowed.

Death from Chloroform.—Another death from chloroform is reported. The occasion was the removal of a fibrous tumor from the palate of a robust and healthy man, aged forty-five years, a patient of St. Mary's Hospital, London. The patient refused to submit to the operation without an anæsthetic, and before he was fully under the influence of chloroform death took place.

The International Congress of Ophthalmology will be held in Chickering Hall, Fifth avenue, on Tuesday, Wednesday, and Thursday, September 12th, 13th, and 14th. On Tuesday, from 12 M. until 1.30 P.M.; in the afternoon, from 3 until 5. On Wednesday and Thursday: in the morning, from 10.30 to 1 P.M.; in the afternoon, from 3 to 5. Candidates for membership will present their names to Drs. Derby or Gruening, at Chickering Hall, on the Monday preceding, at 10 or 3 o'clock, or on the morning of the meeting. The membership fee is $3, including a copy of the reports; without reports, $2. Those who have already subscribed to the expenses of the Congress will be exempt from these payments. The discussions are open to the profession. No paper must exceed fifteen minutes in reading, and no subsequent speech must exceed five minutes. No member must speak more than once upon the same subject, except by permission of the house. A dinner will be given to the foreign members of the Congress by the American Ophthalmological Society, on Thursday evening, September 14th, at Delmonico's. Tickets may be procured on registration.

American Dermatological Association.—At an informal meeting of Dermatologists, held in Philadelphia, at the rooms of the Section of Practical Medicine, of the American Medical Association, Wednesday, June 7th, 1876, after the election of a chairman and Secretary pro tem., it was *Resolved* to call upon such American physicians as had evinced a special interest in dermatology, to unite in forming an American Dermatological Association; *Resolved*, that the meeting for organization be held in the University of Pennsylvania, Philadelphia, on Wednesday, September 8th, 1876, at 6 P.M., or immediately after the close of the meeting of the Section of Dermatology and Syphilology of the International Medical Congress, on that day.

Prof. Joseph Lister and Argyll Robertson, about to visit this country, will represent the Medico-Chirurgical Society of Edinburgh at the International Congress. Mr. William Adams, President, and Mr. Richard Davy, Surgical Secretary, Medical Society of London, will arrive in New York by the *Scythia* on the 15th of August.

Original Communications.

THE INFLUENCE OF NEURALGIA OF THE TRIGEMINUS IN CAUSING IRITIS AND CHOROIDITIS, AND ITS PATHOLOGICAL SIGNIFICANCE.

By CHARLES S. BULL, A.M., M.D.,

OPHTHALMIC SURGEON TO CHARITY HOSPITAL, ASSISTANT SURGEON TO THE NEW YORK EYE INFIRMARY.

For more than a year past my attention has been attracted by certain phenomena of a nervous nature, in connection with iritis and choroiditis, which seem to me to illustrate the intimate connection which exists between neuralgia of the trigeminus and intraocular inflammation, when involving the iris and choroid; and the two forms of disease, neuritis of one or more branches of the fifth nerve, on the one hand, and intercurrent iritis or choroiditis, on the other, I think bear the relation to each other of cause and effect. This view I have been induced to consider highly probable, from my own observation of seven cases.

The pathology of the trigeminus is still very obscure, and investigators are still groping in the dark, or in what, at best, is a very subdued light, for some slight ray that may help their footsteps along in the right direction towards a full comprehension of the subject.

Clinical facts are what we all need, either in advocating or opposing a theory, and, therefore, to the broad field of clinical observation must we look for aid in elucidating the difficulties which overhang still a very important subject. Neuralgia of the trigeminus is an affection of great interest, not only on account of its frequent occurrence and obstinate resistance to treatment, but also on account of its connection with other lesions, which are sometimes of a most intricate nature. Many pages have been written upon the single subject of herpes zoster ophthalmicus, in connection with neuralgia of different branches of the supraorbital and infraorbital nerves, and a great deal of valuable time and arduous labor spent in attempting to account satisfactorily for the occurrence of necrotic inflammation of the cornea and iris, which is met with in this disease.

Neuralgia of the fifth nerve is usually complicated with secondary affections of other nerves, which are intimately connected with those that are the original seat of the pain. When the pain in the nerve is the result of direct injury to the nerve trunk, whether by external violence, by the mechanical pressure of a tumor, or by the nerve becoming involved in some inflammatory or ulcerative process, the general condition of the patient produces scarcely any effect. In general migraine it is a well-known fact that the pain spreads to every terminal branch of the ophthalmic division, the eye on the affected side is deeply injected, there is lachrymation, photophobia and partial ptosis, with occasional spasmodic contractions of the orbicular muscle, and cloudy vision.

In a tabulated report of 128 cases of neuralgia of the fifth nerve in the *Arch. Gén. de Médecine*, Notta says that the retina was completely or almost paralyzed in ten cases; there was dilatation of the conjunctival vessels in 31 cases; permanent tonic spasm, not due to photophobia, in four cases; paralysis of the third nerve, causing ptosis, in six cases; and divergent strabismus in three cases. The pupil was dilated in three cases, and contracted in two cases, without impaired vision. In three others there was a dilated pupil with impaired vision. He also mentions among the complications, glaucoma and ulceration of the cornea.

Now the relations of the fifth nerve to so important an organ as the eye, tend to call our attention strongly to the phenomena that accompany its morbid conditions. Not merely the circulation of the parts supplied by this nerve becomes affected, but also the nutrition of the tissues. Anstie tells us that the periosteum of bone and the fibrous fasciæ in the neighborhood of the painful points not unfrequently take on a condition of subacute inflammation, with marked thickening and tenderness on pressure. He considers also that glaucoma is in many cases of nervous origin, and in this opinion all ophthalmologists will coincide. In regard to this subject, Bowman first called attention to the interesting fact that in certain glaucomatous conditions, there occurs a rapid change in the intraocular pressure; sometimes an increase, at others a decrease. The anomalies of tension are generally transient and of a varying nature. Of course we leave out of consideration all those conditions described as atrophy of the eyeball, in which the softness of the globe depends on disorganization of the tissues and an altered intraocular circulation. We are still very ignorant of the physiological conditions which are here concerned. The hypotonia, or loss of tension, is constantly associated with contraction of the pupil. The patient complains of a dull pain in the eye, or of stabbing pains in the orbit, and in many cases there is violent neuralgia, which often merges into migraine. The spontaneous neuralgic pains generally occur periodically, often accompanied by injection of the conjunctiva and lachrymation. During this rapid change of tension, we should always carefully note the relation existing between the hypotonia and the size of the pupil; when the pupil is narrowest the eye is the softest, and the neuralgia generally the most severe. The hypotonia is very often accompanied by slight chemosis of the conjunctiva and by small, delicate vesicles or phlyctænulæ. Another symptom is the local change of temperature, generally an increase, though occasionally a diminution has been observed. There is also congestion of the corresponding half of the face, and hyperæmia and swelling of the nasal mucous membrane. These cases differ from one another in the prominence of the individual symptoms; in one there are merely changes in tension, in another there is increase of temperature, while in a third the functional symptoms are the most important. *Jonathan Hutchinson* has written much upon the subject in the published reports of the Moorfields Ophthalmic Hospital, and he has come to the following conclusions:

1st. The whole subject of reflex paralysis and reflex disturbance of nutrition is obscure and difficult of satisfactory proof. In some cases it is not at all certain that a central disease does not exist, to which both the lesion of sensation and the lesion of nutrition are alike due.

2d. In many cases the changes are probably due to influences exerted through the vaso-motor nerves only, by which are induced alterations of the blood supply to the affected part.

3d. It is, however, probable that nutritive alterations may be induced through the nervous system independently of any primary change in the calibre of the blood-vessels.

He cites, in detail, 17 cases, one of which was glaucoma of one eye, occurring during a severe attack of neuralgia of the fifth nerve.

Comparatively recent investigations have proven that the phenomena of recurrent sensibility occur in almost all nerves. It is tolerably rare in neuralgia to find the whole of the nerve-trunk the seat of pain. The pain is commonly referred to certain limited spots, pressure upon which will at once induce it. As *Valleix* first pointed out, the most superficial nerves are principally affected, and their points of emergence on the surface the chief seats of pain. *Arloing* and *Tripier* proved experimentally that all nerves—motor, sensitive, and sensory-motor—possess recurrent fibres, which become more numerous as the nerve approaches the periphery, and decrease in number as we go back towards the centre, until they finally disappear altogether. As these recurrent fibres have never been seen to terminate in the thickness of the nerve-bundles, they may be assumed, from the characters noted, to end at different points in the tissues adjoining nerve-trunks or their branches. It is these fibres that, in certain cases of neuralgia, would be affected by morbific agents, which may possibly explain the occurrence of the isolated painful spots on nerve-trunks and their branches. Another argument in favor of this hypothesis, *Arloing* and *Tripier* find in the diminution, or even total disappearance of these fibres above the points indicated by *Valleix*, as the special seats of neuralgic pain. It would be erroneous to assert that these fibres are alone affected in neuralgia; yet equally far from the truth to state that spontaneous neuralgia follows the course of the nerve. They also consider it supposable that the morbid agency acts at once, both on direct and recurrent fibres; consequently if we examine the mode of extension of the neuralgia, from the disordered nerve to one that is sound, an additional argument for their theory is afforded. It is certain that extension very often takes place through the medium of the nerve centres, as is exemplified in the frequent coincidence of trifacial neuralgia, with pain in the cervical nerves. In trifacial neuralgia, it is not uncommon for the pain to glance from the ophthalmic branch to the mastoid process, and upper part of the neck.

In cases of traumatic neuralgia, it is impossible accurately to determine always the amount of nerve lesion in individual cases, and hence it is not always possible to study the relation between the extent of nerve injury and the amount of consequent shock.

It might be supposed from the frequent occurrence of injuries to the eyeball and orbital margins, that wounds of the infraorbital and supraorbital nerves would be not uncommon accidents; but this is not so. They are sufficiently rare, though they do occur. *Weir Mitchell* has seen severe neuralgia of these nerves, where both had been contused by a single blow from the head of a cane.

Charcot mentions the case of a man, who after receiving a violent blow upon the side of the head, which fractured the outer table of the parietal and adjoining portion of the frontal bone, complained of constant, violent pain in the branches of the frontal and occipital nerves. Later, the neuralgia became localized in the right eye, orbit, and ear; the eye became red and prominent; the conjunctiva œdematous, and the upper lid paralyzed. The cornea was hazy, and there was iritis with synechiæ.

Perhaps the most curious and interesting feature of these cases of iritis and choroiditis, is the strange variations in intraocular pressure, and their connection with the activity of the inflammation and the severity of the neuralgia. Close observation of the seven cases which I have been able to follow out, have led me to the conclusion that, as a rule, the beginning of the pain leads to a slight diminution of tension, which rapidly becomes more marked as the inflammatory action proceeds, and is lowest when the latter has reached its height. Without entering upon a discussion of the subject of intraocular pressure, let me say a few words in regard to the influence of the fifth nerve.

By irritating the medulla at the deep origin of the fifth nerve, the intraocular pressure is always increased, and lasts some time after cessation of the irritation. The result of irritation of the fifth is always the same, whether the cervical sympathetic was previously divided or not. The explanation is probably as follows: The first cause of increased tension is an active dilatation of the blood-vessels of the choroid and iris; the fact that the irritation of the fifth nerve increases the tension, even after evacuation of the aqueous humor, proves that a secretion or transudation of the ocular fluids occurs somewhere during this irritation. It is further proved by another experiment; if we divide the spinal cord between the occiput and the third cervical vertebra, no considerable increase of intraocular tension is produced, but when the fifth nerve is irritated in the same nimal, there is.

A final legitimate conclusion may be stated somewhat as follows: In some way, either peripherically or centrally, the trigeminus is irritated; as the immediate result, there occurs a slight increase of intraocular tension, caused by increased secretion of fluid in the posterior segment of the eyeball, by which the iris and lens are pushed forward; by the pulling of the zonula upon the latter, a new irritation is set up, which again acts on the secretory nerves, and, of course, causes an increase of tension. As a secondary result of the pressure, the points of exit of the venæ vorticosæ are narrowed, and we get disturbance of the circulation. But the cause of the intercurrent inflammatory action is still undecided and obscure.

As a résumé of still later investigations of *Hippel* and *Grünhagen*, the following may be offered: The trigeminus, by dilatation of the vessels of the iris and choroid, and by diminution of the resistance to osmosis, can cause an increase of the intraocular pressure. The sympathetic, as the specific ocular nerve, when irritated at the superior cervical ganglion, causes diminution of the intraocular tension. In the history of glaucomatous cases, as well as of those of essential phthisis bulbi, there is an irritated state of the ciliary nerves. Now since all sensory nerves stand in reflex connection with the vaso-motor nerves in general, and particularly with those of the eye, the irritated condition of the ciliary nerves may easily extend to the vaso-motor nerves of the eye, and may induce periodically or permanently contraction of the blood-vessels, a lessened supply of blood, and a consequent diminution of the tension of the eye. This I hold to be the explanation of the phenomenon of diminished tension which occurred in all the cases of iritis and choroiditis which formed the basis for this paper. In all of them it was present, and in most of them very marked, and always showed an intimate connection with the state of the pupil and the degree of inflammatory action.

It is well known that, in the majority of cases, the affections of the eye, which occur simultaneously with, or subsequent to neuralgia of the peripherical branches of the trigeminus, consist in periorbital neuralgia, accommodative asthenopia, spasms of the orbicular and facial muscles, and the more serious lesions of the cornea and conjunctiva. We also know that

these attacks of neuralgia are due to an inflammation of one or more of the terminal twigs of the ophthalmic division of the fifth. Now it is a matter of experience that the supraorbital or frontal branch is the most often inflamed, and the neuralgia is very often characterized by evening exacerbations. *Galezowski* cites a remarkable case of this kind of neuralgia in a patient from whom he had removed one eye three years before for hemorrhagic glaucoma, and had done an iridectomy in the other for chronic glaucoma. In this eye vision was restored and remained good for three years. He was then attacked by periodical neuralgia of the orbital margins, which was very violent; the eye became red, and vision was considerably impaired. *Galezowski*, at first, thought that it was a return of the glaucoma, but a closer examination showed that the disturbed vision was due to excessive lachrymation, and the case proved to be a true neuritis of the supraorbital nerve, which he cured by a succession of blisters.

If this frontal neuritis is not arrested, and if the neuralgic symptoms are prolonged during weeks and months, there result, very often, spasmodic contractions of the muscles of the face and lids. Here the case becomes more serious, and we must resort to subcutaneous division of the supraorbital and infraorbital nerves, and even to an exsection of a portion of them.

Some authors are inclined to believe that if the inflammatory action affects the peripheral twig, the eye complications are very superficial, are most often purely neuralgic and rarely inflammatory; and that the more serious lesions of the iris and choroid are only met with when a deeper portion of the trigeminus is involved, viz. the ganglion of Gasser; and that when a cerebral lesion is at the bottom of the trouble, there is such an alteration in the nutritive centres of the eye that the most serious results are here met with. This reasoning I believe to be faulty, for cases of grave choroidal lesion certainly do occur where vision is practically abolished, where there is surely no cerebral lesion present, nor even any suspicion of one, but where the intraocular trouble is due solely to peripheral irritation.

In glancing over the current ophthalmic literature of the past few years we are surprised to find how few cases there are published of grave lesion following neuralgic affections of the fifth nerve; and still more rare are those cases which are not glaucomatous, in which there is a *diminution* of tension associated with iritis or irido-choroiditis.

In the Transactions of the American Ophthalmological Society for 1870, Roosa mentions a case of conjunctival and corneal lesion with partial ptosis, in which, for nine months, there occurred every week with great regularity conjunctival injection of one eye with neuralgia, both ciliary and frontal, contraction and sluggishness of the pupil, lachrymation and diminution of tension. Only the ocular conjunctiva was injected, especially on the nasal side, but there were never any signs of herpes. The attack lasted several hours, and no treatment was of much use. After nine months the attacks became rarer, and finally ceased.

Noyes somewhere reports a case of monolateral herpes zoster ophthalmicus with bilateral blindness, which is of interest in view of the immediate cause of the loss of vision. There was the usual eruption on the left side of the face, accompanied by very violent and continuous neuralgia of the same side. The *left* eye became blind during the attack, but not from ulceration of the cornea. Ten months later the right eye became inflamed and vision was lost, just as the left one was, from irido-choroiditis, without any eruption on the right side of the face.

It may seem to some that seven cases are far too few to draw conclusions from, but we certainly can learn something from a careful observation of even this small number. In five of the cases, the patients had been neuralgic for a number of years, and in one of these since early childhood. Two cases were of traumatic origin; that is, the neuralgia was caused by direct injury to the nerve branches, and in both of them the nerves were involved in the resulting cicatrices. In all seven the same symptoms were noted.

After the neuralgia had lasted for some time, usually months, a very violent attack occurred, accompanied by marked conjunctival injection and diminished tension, followed by a sharp iritis, during which the tension rapidly decreased, the pupil remained contracted in spite of atropine, though not always from adhesions, and the neuralgia ceased. During the height of the inflammation the tension remained diminished, but when the inflammation began to yield, the tension began to increase and the pupil to dilate. With each fresh relapse, the same symptoms followed in usually the same order, and the choroid generally soon became involved. In only one case was there ever any conjunctival herpes, and in this case the vesicles always appeared at the inner angle, near the caruncle. The prognosis is almost always bad, for the neuralgic habit is almost permanent, and with each attack of neuralgia, the eye is almost sure to sympathize after the first attack of iritis. Of course when the choroid is involved, the aspect of the case becomes a grave one.

Case I.—*Long-continued Neuralgia of Frontal Nerve, followed by suppurative Irido-choroiditis and sympathetic Iritis in other eye.*

Patrick D., æt. 35, laborer; subject to frontal neuralgia of right side for nine years. At first, attacks slight in intensity and duration, and at moderately long intervals of three or four weeks; but gradually became more frequent, and increased in duration and severity, and for past year have occurred every day. Pain generally confined to frontal nerve and its branches, but occasionally invade cheek and orbit. Neuralgia always succeeded or accompanied by photophobia, lachrymation, and active injection of ocular conjunctiva, but V. never materially disturbed till six weeks ago. At this time neuralgia very intense, and accompanied by violent inflammation in eye. V. failed rapidly, and in less than 48 hours was entirely destroyed. Cornea ruptured, lens was extended, and eyeball rapidly degenerated from panophthalmitis. Since then, frontal neuralgia intermittent and less severe, but can always be excited by pressure on nerve. Six weeks after, violent inflammation, nothing left but small, very painful stump. Complete ptosis from paralysis of levator palpebræ, and plastic iritis in fellow eye with V. = $\frac{20}{200}$. Stump of R. E. immediately enucleated, and subsequently iridectomy upwards in L. E. with good result.

Case II.—*Irido-choroiditis following violent and continued Frontal Neuralgia of possibly traumatic origin.*

Ann H., æt. 55. Eight months before I saw patient, she was struck on forehead over R. E. by a large box falling upon her. Blow knocked her down, and in falling she received a severe wound over occiput from corner of chair. Was unconscious, and afterwards complained of diplopia and misty vision. When I saw her, there was a broad scar just above eye-

brow, 1½ inch long, across course of frontal nerve. Three weeks after accident, severe attack of frontal neuralgia, which lasted three days, accompanied by usual ocular symptoms. Attacks became more frequent, until now they occur every day. Three weeks ago, attack ushered in by violent inflammation of eye with marked failure of V. When I saw her, there was violent irido-choroiditis, discolored iris, immovable pupil, cloudy vitreous, diminished tension, V= fingers at two feet. Intense pain over whole side of face, and seemed to involve all branches of fifth. Atropine (gr. iv.), warm applications, and leeches, and one week later, iridectomy upwards. After five weeks of continued treatment, media cleared up, and neuralgia disappeared. V=$\frac{20}{100}$, and atrophic changes in choroid. After intermission of three weeks, neuralgia returned in frontal nerve; and with each exacerbation the eye became injected and painful, and one month after operation, second attack of violent irido-choroiditis which lasted five weeks, and neuralgia became almost constant. After ultimate subsidence of inflammation, V=$\frac{5}{200}$, and never improved. Neuralgic attacks grew less frequent and finally disappeared.

Case III.—*Irido-choroiditis, with diminished tension following contused and lacerated wound of forehead in region of frontal nerve, with obstinate neuralgia.*

Ellen C., æt. 72. Nine weeks before I saw her, patient had fallen down-stairs and struck forehead just above orbital margin, on edge of step. Profuse hemorrhage from wound, and unconsciousness for several hours. When she recovered, vision found uninjured, though she had never seen well, owing to high degree of myopia. Wound healed very slowly, and always very painful. Three weeks after accident pain became neuralgic, very severe, and involved all cutaneous nerves on right side of face, scalp and neck. On each return of neuralgia, sharp flashes of light before R. E., and V. became cloudy. When I saw her there was a scar an inch long just above right eyebrow, still red and painful—irido-choroiditis with posterior synechiæ, and cloudy vitreous. Tension markedly diminished, V.=movements of hand. In L. E., V=fingers at 20 feet with a myopia ¼, and extensive choroidal atrophy. Patient refused all operative interference. Three weeks later, returned with intense pain in R. E., V=0, and iritis in L. E. Iridectomy upwards in both eyes, and after long continued treatment by atropine, warm applications, repeated leeching and mercurials, inflammation subsided in both eyes, leaving V. in L. E. same as before; and neuralgia diminished in intensity and frequency, though it never was entirely cured.

Case IV.—*Optic Neuritis, followed by Irido-choroiditis, preceded by intense neuralgia of scalp and face of right side, of traumatic origin.*

Betty H., æt. 42. Three days before I saw her, she received violent blow on right side of face and head. No external wound, but next morning eyelids swollen and ecchymosed. No injury to conjunctiva, cornea, or iris, media clear, optic disk and retina normal, V.=$\frac{20}{30}$. Sharp intermittent pain in orbit and along forehead. Great pain on pressure over frontal nerve. No syphilitic, rheumatic, or gouty taint in patient. Neuralgia spread all over right side of face and scalp, and increased in severity. Three weeks after accident, vision began suddenly to fail very rapidly, and was reduced to counting fingers at six feet. Ophthalmoscope showed well-marked optic neuritis, with all the usual signs, but no hemorrhages. Leeches, atropine, mercurial inunction. Three days later, after violent neuralgia, irido-choroiditis developed, with marked diminution of tension. Same treatment persevered in, and after three weeks inflammation subsided, and vitreous began to clear up, and at end of sixth week the optic neuritis had subsided, leaving the disk somewhat paler than natural, but V.=$\frac{20}{40}$. Tenderness and neuralgic pain also diminished markedly, and eventually entirely disappeared from all branches of 5th except frontal, which was involved in scar. This case seems to show an intimate connection between trifacial and optic nerves. Neuritis of branches of 5th set up by injury seemed to be propagated from periphery towards centre, while neuritis of optic nerve seemed to have taken reverse course. Whether irritation of 5th travelled as far as nuclei of origin and was then reflected along fibres of optic nerve, may be regarded as somewhat doubtful. I am inclined to doubt existence of any serious inflammation in course of optic nerve downwards in this case, for this would probably not have yielded so readily to treatment, and would almost certainly have left disastrous results. The neuritis here probably limited to ocular end of nerve, and the medium of production may have been a disturbance in vaso-motor system presiding over circulation and nutrition of optic nerve, propagated to them from the 5th, either peripherically or from the centre, probably the former.

Case V.—*Irido-choroiditis following long continued Neuralgia of 1st and 2d branches of 5th nerve, with diminished tension, and ending in phthisis bulbi.*

Mrs. B. æt. 38. Seen in consultation in May, 1875. Perfectly healthy up to five years ago. First marriage at 20, but no children. Has had one child by second husband. Subject almost constantly to neuralgia of lumbar and dorsal regions for two years, but for last three years the pain has been confined to supraorbital and infraorbital nerves. These attacks occurred at irregular intervals and were of varying duration. Always confined to left side of face, and gradually increased in frequency and severity. Three months before I saw patient, after violent supraorbital neuralgia, a violent iritis set in, with marked diminution of vision. This resisted all treatment, and in time the fellow eye became involved sympathetically. On my last visit, I found in L. E., extensive irido-choroiditis, diminished tension, cloudy vitreous, limitation of visual field on temporal side V.=$\frac{5}{200}$. In R. E. iritis and posterior synechiæ. Iridectomy upwards immediately in L. E., leeches to both temples, atropine (gr. iv.) every half hour in both eyes, and mercurial inunction. Phosphorus, quinine, and nux vomica internally. Wound healed well, and in course of two weeks R. E. recovered entirely and vision improved somewhat in L. E. But no appreciable change in attacks of neuralgia. Three weeks after operation, a severe exacerbation of neuralgia, followed in less than an hour by severe irido-choroiditis in L. E., vision reduced to perception of light, and inflammation only yielded to treatment after two weeks. From this time the tension remained permanently diminished, though each attack of neuralgia was immediately followed by an increase of tension, which soon gave place to diminution below the previous degree. After a third relapse, R. E. again became affected with limitation of field and failing vision, and enucleation of L. E. advised, but was refused. Vision of L. E. permanently reduced to perceiving movements of hand. R. E. V.=$\frac{20}{100}$ with limitation on nasal side. The neuralgia remained just as severe, and each exacerbation was followed by recur-

rence of inflammation in L. E., and threatening symptoms in R. E.

CASE VI.—*Irido-choroiditis with marked diminution of tension, preceded for several months by neuralgia of frontal nerve, following fracture of the bones of the face.*

Bernard B., æt. 45, laborer. Two years before I saw the patient he had received a violent kick on right side of face from a horse. Blow had fractured orbital plate of superior maxillary, had driven in and comminuted malar bone, had fractured external angle of frontal bone and both nasal bones, causing deep depression between the eyes. Whole right orbit displaced downwards and outwards, so that inferior orbital margin stood ½ of an inch lower than opposite side. Sight of R. E. lost at time of accident, and globe had slowly atrophied without any pain, until when I saw him there was only a small stump left. He had no pain of any kind on right side after wounds had healed, but about a month after accident he began to suffer from severe pain on left side of nose and at inner angle of left eye, which was irregular in appearance and duration at first, but gradually became continuous, and subsequently involved infra-orbital nerve. These attacks became so bad that he was unable to do any work, and three weeks before I saw him the vision of left eye became seriously affected. I found severe neuralgia of naso-ciliary and infra-orbital branches of 5th on left side, partial ptosis of upper lid, injected conjunctiva, turbid aqueous, contracted pupil, irido-choroiditis and marked diminution of tension. Stump of R. E. immediately removed, and atropine, leeches to temple, phosphorus and quinine. On 4th day some slight improvement, pupil moderately though irregularly dilated, vitreous turbid, tension still diminished: V.= movements of hand. Slow but steady improvement in all symptoms till 9th day, when violent recurrence of neuralgia began, followed by relapse of irido-choroiditis, marked diminution of tension, no perception of light, and increased severity of pain. Iridectomy immediately done upwards and in course of an hour, ciliary pain ceased, though infra-orbital neuralgia still continued. Inflammatory symptoms slowly subsided, and some vision returned. Aqueous and vitreous cleared up, and two weeks after the operation choroid could be seen filled with exudation, floating bodies in vitreous, and = $V\frac{1}{20}$. Tension remained diminished for some weeks after operation, but finally reached normal standard. Circumorbital neuralgia diminished in severity and frequency, but was not entirely removed. No syphilitic or rheumatic taint in the case. May it not be probable that, as a consequence of fracture of nasal bones, the line of fracture may have extended into superior maxillary bone of left side, and injured terminal fibres of nasal nerve, or even the infraorbital nerve; or that, in process of healing, these nerves may have been compressed, thus giving rise to their inflammation and the consequent neuralgia?

CASE VII.—*Long-continued facial neuralgia, followed by iritis with deposit on membrane of Descemet, and subsequently choroiditis with exudation, with frequent relapses.*

Mrs. M., æt. 50. I first saw patient in June, 1875. She had been neuralgic from early childhood, and for many years had led a somewhat confined, sedentary life. The neuralgia was for many years general, occurring all over the body, but of late years they have been limited to the head and face, and more particularly to the right side. Six years ago had a violent attack of plastic iritis in R. E. Vision was seriously impaired, and inflammatory process lasted eight weeks. During this period the patient was entirely free from neuralgia, but as inflammation subsided, the neuralgia began to return, and was soon back in full force. The eye remained weak and irritable for a number of weeks, and she suffered from repeated attacks of conjunctival herpes. These were somewhat irregular, usually coming about once a month and lasting three or four days. Always ushered in by attack of frontal or infra-orbital neuralgia, and strangely enough confined to inner angle of eye, near semilunar fold and caruncle. During their presence the neuralgia ceased, to reappear on the subsidence of the vesicles. These attacks of herpes occurred with varying regularity up to March, 1875, when she had a more severe and prolonged attack, which left the eye weak and irritable, and early in April an attack of iritis supervened in one eye, with punctate precipitate on membrane of Descemet. At this time neuralgia very severe. Between this attack and June 17th, when I first saw her, she had four relapses of iritis. At my first visit there were numerous punctate deposits on posterior surface of cornea, iris discolored and adherent to capsule below, cloudy vitreous, tension diminished, and neuralgia violent. From this time up to Oct. 10th, she had five more relapses, each one severer than the preceding, and vision became seriously and permanently impaired, as the choroid was deeply involved. On Oct. 17th, a broad iridectomy was done upwards, after which there was very severe pain. But wound healed well, the inflammation subsided, tension increased, the neuralgia diminished markedly, and vision improved decidedly. Patient's condition steadily improved, and there was no further relapse till latter part of February. Since this period, she has had three relapses, and vision has sunk to counting fingers at a few feet. The facial neuralgia, however, is decidedly better, the attacks being much less frequent and less severe.

As regards the operation of iridectomy in these cases, a few words may not be amiss. Since the performance of this operation for making an artificial pupil, and more recently as a remedy for glaucoma, has made it widely known, it has become of such general practice in all sorts of cases, as to bring down upon itself from ophthalmologists during the past few years an amount of odium which is, I think, undeserved. The reaction has been too violent, and the pendulum of surgical opinion has swung so far in the opposite direction as to excite apprehensions that it will not swing back. There is no doubt that the operation has been performed in many cases, not only where it was not indicated, but also in many where it was strongly contra-indicated, as in cases of violent inflammatory action. Its ultimate disturbing influence upon vision has not been sufficiently considered by its too ardent advocates, and like many another medical or surgical remedy, it has been regarded as a sort of universal panacea for most of the deeper lesions of the eye. But recognizing this fact, it will not by any means do to reject it, as too many have done, and consign it to the limbo of surgical oblivion.

In the subject under consideration, in iritis and choroiditis, we may still safely trust ourselves to the dictum of our great master, von Graefe, who writes as follows:

"It is not iritis itself, the single acute attack, which in the majority of cases threatens the vision or even the loss of the eye, but the frequent relapses, which always cause new exudations into the pupil, and frequently its complete closure. In many of these cases the real origin of the evil lies in the eye itself, in the posterior synechiæ. The periodic ciliary neurosis, so

common in these cases, often depends solely on the presence of these posterior synechiæ. The closure of the pupil forms the point of origin of further complications, particularly chronic choroiditis and phthisis bulbi. Where atropine fails to break up the synechiæ, and relapses continue to occur, there is but one resource left us, the performance of an iridectomy, which should be so done as to break or tear away the broadest synechiæ, and thus do away with the exciting cause."

From my own experience, while admitting that even an iridectomy does not always succeed in preventing the relapses in these cases complicated by a diseased trigeminus, yet I certainly would not postpone the operation till the eye had become seriously damaged by the relapses, but would do it as soon as it was evident that the ordinary means of treatment had failed.

DAMIANA.

By ALEXANDER MURRAY, M.D.,

NEW YORK.

As a new remedy, Damiana is now doubtless engaging the general attention of the profession. My friend Dr. J. J. Caldwell, of Baltimore (formerly of New York), has published an interesting article on its use, etc.* After reading his paper, I was desirous of testing its therapeutic value in nervous diseases, but more especially as an aphrodisiac.

The desideratum most needed in certain nervous affections, is a reliable substitute for phosphorus. For this agent when taken internally, even in very small doses frequently repeated, is not altogether free from danger, no matter with what menstruum it may be combined—as oil, wax, lard, alcohol, ether, sugar of milk. After a few doses are taken, it invariably produces a sensation of burning at the pit of the stomach, and also disagreeable eructations of gas, which have a phosphoric taste and odor, or as some patients have expressed it, as if "a box of matches had been swallowed."

With this inducement, therefore, in addition to that general desire to advance the healing art, more particularly in a direction where of all others it seemed most to require it, I proceeded to make trial of damiana in a number of cases which happened to offer; encouraged with the hope that, since we already had obtained, in bromide of potassium, a means of repressing the sexual impulse, we might find in the other article a means of exalting it, and thus have it in our power to satisfy both classes of patients, as well as those laboring with priapism on the one hand, and those with prostration on the other.

Case I. was that of a lady, aged 24, of a highly hysterical constitution, who had married about three years. Her menstruation was always regular, but scanty, of a pale color, and unattended with pain. She informed her husband that about a year previous to her marriage she had lost all sexual desire, owing, as she alleged, to a paroxysm of hysterical convulsions. She had strong hopes that the influence of matrimony would restore the lost appetite.

Her husband manifested great anxiety for her recovery, and especially as he was desirous of having family. A careful examination of the organs of generation showed that they were normal and healthy.

I was determined in this case to give damiana a fair trial, in order to test its real or therapeutical value. I began treatment by giving the fluid extract in two-drachm doses three times a day for one month, and then an ounce and a half in divided doses for the succeeding two months. During the third month she imagined she had recovered somewhat her sexual appetite. The use of the drug, however, produced a decided change in her physical appearance, making her robust and healthy, whereas before she had been thin and pale. She was naturally of a constipated habit, and consequently required the occasional use of purgatives. After the extract of damiana had been taken for a few days, it produced large soft alvine evacuations, and subsequently the menstrual flow was both normal in quantity and color. The latter effect, I believe, was due altogether to the improved condition of her health, rather than to any emmenagogue properties in the drug.

Case II.—Mr. K——, aged 42 years, a native of Germany, merchant, had always enjoyed good health; never had syphilis or any other disease, that he is aware of; and had not at any time indulged in the excessive use of stimulants or tobacco. About six months after his second marriage, he experienced marked sexual weakness. He attributed the cause of his weakened powers to having been allowed, through neglect of the attendants, while taking a vapor or Russian bath, to remain too long on his back on a heated marble slab. He also stated that the excessive inhalation of steam during the sweating process, produced palpitation of the heart, difficult breathing, and a sense of immediate suffocation. Soon after he left the bath-rooms he had a slight attack of vertigo, and experienced great difficulty in walking to his residence, which was about four blocks off.

Two months before he came under my observation, he had been treated for impotence by a "charlatan," who, under the promise of a speedy cure, fleeced him out of a large sum of money. Mental despondency arising from the cares of business, with his anxiety concerning his young wife, drove him to the verge of insanity.

After a careful review of his case, I was doubtful of obtaining satisfactory results by any mode of treatment whatever, and accordingly held out no promise of success. However, I applied galvanism (interrupted current) to the spine every second or third day, for four weeks, and gave the fluid extract of damiana in half-ounce doses, thrice daily for nearly nine weeks. About three months from the commencement of treatment he stated, to use his own words, that "he was a man again," and expressed himself very desirous of continuing the damiana.

Case III.—John B——, 28 years, a robust, healthy-looking person; a house carpenter; never had syphilis; married about nine months. He attributed the cause of impotency to the taunts of his wife, whose propensities were stronger than his own. The consequence of this was the most unbridled excess in sexual indulgence during the first six months of matrimony. He was very despondent at times, and threatened to commit suicide in the despair of a cure. Separation from his wife for a time, cheerful society, and the administration of damiana, resulted in about two months in restoring the sexual ability.

Case IV.—Mr. Charles H——, æt. 34; clerk; short, stout, and vigorous; while walking, fell and hurt his spine. He complained of severe pain in the lower part of the back (sacro-coccygeal region) and the left thigh. Micturition was for several days both painful and difficult. The shock to the spine produced impotency. He had neither desire for, nor power of coi-

* Virginia Medical Monthly, May, 1875.

tion. His wife, a good sensible woman, consoled him, and encouraged the hope that time and medical treatment would restore the lost functions.

About three weeks from the date of injury, faradization was employed daily to the spine for eight applications. As he was unable to attend to business, he resolved to go into the country for a short time until recruited. I supplied him with the fluid extract of damiana sufficient for six weeks, with directions to take four drachms three times a day. He called to see me after an absence of two months, and reported that there was a marked improvement in his sexual ability. Subsequently, after two weeks by too frequent marital intercourse, a diminution of virile power was apparent, and consequently he fell back on damiana for a few weeks longer. Moderate indulgence was now strictly enjoined.

Case V.—Mr. R——, æt. 46; a lawyer; had syphilis when a young man. He had an attack of apoplexy about four years ago, and for several days was in a precarious condition, but he gradually recovered consciousness, leaving the left side completely paralyzed. By judicious treatment and repeated applications of faradism, he was able in six weeks to walk about, and in less than three months to follow his professional avocations. Although sufficiently recovered to attend to his business, still, he had been quite frequently despondent, as he experienced a marked loss of sexual ability. For this ailment he had consulted several physicians, followed their advice, and had used phosphorus, strychnia, ergot, and electricity, without any apparent effect in restoring his virile power.

For more than two years he had given up all treatment as useless. I advised him to give damiana a steady trial for at least two months, at the end of which time to let me know the result. There was a decided improvement in his condition. The power of erection, however, was not altogether satisfactory, and though at times it was sufficient to complete the sexual act, yet, it very often failed at the important moment. His recovery, although not complete, had exceeded his anticipations, and encouraged the hope that damiana would ultimately accomplish the desired result.

In a few cases of midwifery—inertia of the uterus—I have given four drachms of the fluid extract every 30 minutes, three succeeding times, without apparently augmenting uterine contraction.

I have noticed that when damiana had been taken for a week or two, it invariably produced (in about two-thirds of my patients) an eruption of acne on the head and body. It also induced large soft evacuations from the bowels, especially in those of a constipated habit. The drug did not act as a laxative, but more as an alterative—in fact, somewhat similar in its results to the extract of belladonna, when administered in chronic constipation.

I did not observe any marked effect on the heart, liver, stomach, or bladder. In a few instances I noticed the diminution of the phosphates, and almost the entire absence of the oxalate of lime, which usually appear in the urinary secretion in cases of nervous affections, and especially in cases of impotency.

The value of damiana in impotency is more apparent in stimulating venereal desire than in restoring the vigor or power of the virile member. In several cases, the drug failed to manifest any curative effect, while in others particularly in those arising from an attack of paralysis (hemiplegia), even of six or eight years' standing, it was more or less beneficial.

Damiana is by no means an agreeable remedy to take. The bitter, slightly acrid taste, and the "sassy" flavor are disliked by many patients. It sometimes excites nausea or vomiting, especially when taken on an empty stomach, or when the dose is not largely diluted with some menstruum.

The fluid preparations of damiana, when mixed with water, act somewhat similar to the tincture of guaiac—that is, by forming an opaque mixture or emulsion, of a dirty greenish white color. A combination with a little liquor potassa or water of ammonia forms a tolerably clear solution when diluted with water. The tincture of the chloride of iron changes the fluid extract to a dark bluish-green color.

Generally I prescribe the fluid extract of damiana in combination with equal parts of glycerine and syrup of tolu, or with some fruit syrup. Several of my patients have taken the drug in claret, Rhine wine, or lager-beer, to disguise its taste, while many others prefer the cold fresh infusion. Frequently I have prescribed, as an adjunct, dilute phosphoric acid, from 10 to 15 drops with each dose of damiana. This addition renders it pleasant and easy to take.

The following is the formula of the infusion which I have employed:

Damiana, leaves and flowers	2 oz.
Liquorice root bruised	½ oz.
Boiling water	16 oz.

Macerate for eight hours in a covered vessel, and strain. Dose—2 to 4 ounces.

The preparations of damiana which I have prescribed were prepared by Nickles, 697 Broadway.

Progress of Medical Science.

On Official Dosage, with some Remarks on Homœopathic Tinctures.—Dr. Farquharson contributes an interesting paper on the above subjects to the May number of the *Practitioner*. In the first part of his paper he shows that the maximum doses of digitalis, belladonna, conium, tincture of iron, bromide of potassium, etc., etc., allowed by the British Pharmacopœia are all too small. In the case of tincture of aconite, on the other hand, both the minimum and maximum doses are too large, while the minimum doses of liquor morphiæ, strychnia, and tincture of nux vomica, are all placed too high. He cites several cases in which these mistakes in the official dosage led to serious annoyance to physicians by inducing pharmacists to refuse to put up prescriptions as they were written, and shows how such refusal may gravely imperil the interests and safety of the patients. He urges warmly that something should be done to carry out the suggestions of Anstie, who had, shortly before his death, devoted considerable attention to the subject of official dosage, and recommended the formation of a committee of competent men by the colleges or medical societies to investigate the question.

Dr. Farquharson, however, congratulates us on the fact that the errors in our Pharmacopœia are mostly on the side of caution, and contrasts it with the looseness which prevails in homœopathic pharmacy, in which the feeble dilutions of former years have been replaced by excessively strong tinctures. Dr. G. Johnson cited, in a paper recently read before the Clinical Society, five cases in which unpleasant and even dangerous symptoms followed the use of the concentrated homœopathic solution of camphor, in quantities ranging from eight 2-minim doses up to twenty 25-minims

and a teaspoonful. This solution is stronger than the spt. camphor. of the B. P. in the proportion of 7½ to 1, containing one ounce of camphor to one and a quarter ounce of spirit. Anxious to obtain a correct idea of the strength of some of the homœopathic remedies, Dr. Farquharson tried some experiments with a few of their mother tinctures and metallic solutions. He found by experiment that 15 drops of the mother tincture of aconite were sufficient to kill a rabbit. This tincture about equals in strength the British liniment of aconite. The mother tincture of belladonna is stronger than the tincture of the B. P., 10 ♏ causing on himself dryness of the throat and unpleasant dreams. The homœopathic solution of arsenicum, of which the dose for an adult is one to five drops, contains one grain of arsenious acid to 102 ♏ of water, while the corresponding solution of the British Pharmacopœia contains one grain to 120 ♏ of solvent. A solution labelled "Mercurius cor. Poison. Dose for an adult one to five drops," contained about one grain of the amido-bichloride of mercury to two fluid drachms of alcohol. This is about four times the strength of the solution of perchloride of mercury as ordered in the British Pharmacopœia.

Both these vegetable mother tinctures and the solutions, the latter of which were, it is true, labelled "Poison," were sold freely and without question over the counter of a homœopathic pharmacy. What becomes, then, of the boast of the homœopathists that no mercury or injurious metallic substance is ever prescribed by one of their practitioners? The above figures show how misplaced is the rash confidence of homœopathists in the weakness and innocuousness of their drugs. A mistake in the matter of aconite, for instance, would not be likely to occur to the same patient a second time. Indeed, in view of the careless way in which amateurs recommend and take homœopathic remedies, it does not seem at all improbable that a mother tincture might be mistaken for one of its dilutions. In conclusion Dr. Farquharson cheerfully admits, that although we are supposed to ruin the constitutions of our patients with enormous doses of deleterious substances, we must yield the palm of potency of dosage to those practitioners, the very essence of whose professional existence was formerly believed to depend on the magical effect of their infinitesimal dilutions.

Physiological Chemistry.—MM. Malassez and Picard have lately devoted considerable time to the study of the chemical composition of the spleen, and have discovered that it contains a much larger quantity of iron than the blood which it contains could supply. They pumped into the splenic artery a quantity of a solution of sea salt, until it issued from the vein perfectly colorless. The salt solution drives out the blood mechanically, but does not dissolve any extraneous hemoglobine that exists in the tissue of the spleen. After this process the spleen retained its red color, though it was certainly entirely empty of blood. A quantity of pure water, which dissolves hemoglobine, was then injected into the artery, and when it issued from the vein it had a deep red color. At the same time the organ began to lose its red color and gradually assumed a pale yellowish tinge, the water issuing from the vein losing its red color as the spleen became decolorized. Microscopical examination of this fluid showed no red globules, but the spectroscope and chemical analysis revealed the presence of hemoglobine. It is evident, then, that free hemoglobine exists in the spleen outside of the vascular system, or at least that the organ contains an organic substance that is transformed into hemoglobine by the action even of a vehicle as weak as simple water.

Another physiologist, M. Raoult, has been experimenting with the object of determining the effect of inspired carbonic acid on hematosis. He experimented on rabbits placed in an apparatus so arranged that the expired did not mingle with the inspired air, and which permitted analyses of both to be made, and allowed of changes in the composition of the latter to be made at will. The air inspired contained always a fixed quantity of oxygen, about 21 in the 100 parts, but a certain quantity of the nitrogen was replaced each time by a similar quantity of carbonic acid. The maximum dose of the last used was 24 parts in 100. The number of inspirations per minute diminished in an inverse proportion to the amount of carbonic acid inspired, but they at the same time increased in depth, so that the volume of air inspired in a minute was nearly doubled. At the same time the amount of carbonic acid produced by the pulmonary combustion diminished sensibly; the analyses showed that when 100 cubic inches of inspired air contained 20.8 cub. in. of oxygen, and no carbonic acid at all, 2.8 cub. in. of oxygen were consumed and 2.3 cub. in. of carbonic acid produced; when, however, the inspired air contained 20.8 cub. in. of oxygen, and 12.1 cub. in. of carbonic acid, the oxygen consumed was only 1.1 cub. in., and the carbonic acid produced, 0.9 cub. in. In order to overcome this diminution in consumption and production, the amount of air inspired, as is mentioned above, was nearly doubled, but even this was unable to supply the deficiency, for in the same space of time less oxygen was consumed and less carbonic acid produced.—*La France Médicale*, May 31st, 1876.

Biliary Colic.—In a paper read before the Medical Society of the College of Physicians of Ireland, Dr. Hayden gave the histories of seven cases of biliary colic, with two deaths, one from pyæmia and the other with rigors followed by coma. The special symptoms of the affection are said to be thrilling at the epigastrium, and spasmodic pain extending to the right scapula, accompanied by sudden inflation of the stomach and vomiting, and ceasing abruptly after some hours; the liver is somewhat enlarged and tender on pressure. Jaundice generally appears within twenty-four hours after an attack, the urine being colored with bile, while the fæces exhibit a want of it. After the earlier paroxysms, however, jaundice is not unfrequently absent. The smooth, round, yielding tumor, mentioned by authors as formed by the distended gall-bladder, is very rarely met with. The treatment during a paroxysm consists in hypodermic injections of morphine, the hot bath, and a turpentine enema. Inhalations of chloroform are less efficacious than morphine. In the intervals a few grains of blue pill, with extract of belladonna and dried soda, should be given thrice daily, and occasionally a rhubarb or seidlitz draught. The general treatment with a view to a cure should have reference chiefly to diet and exercise. Food should be taken in moderate quantity and frequently; the bowels should be moved daily, and above all active exercise out of doors should be systematically pursued. Fats, sugar, hot bread, malt drinks, highly spiced dishes, and rich soups should be avoided. Claret, soda, and seltzer water should be freely used. Green vegetables, especially spinach and broccoli, fresh ripe fruit, and plain puddings may be used. The natural alkaline waters should be used both internally and by the bath for one or two seasons; those of Vichy, Carlsbad, and Marienbad are the best. —*Dublin Journal of Medical Science*, April, 1876.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

THE CROTON WATER SUPPLY.

THE discussion in the newspapers concerning the recent smell and taste of the Croton water supplied to the city has directed a considerable amount of attention to the subject, and has given the public some insight into the methods by which the water supply is managed.

So far, every one must be satisfied that the aqueduct department has been doing everything in its power to remedy the evils, and from the start has been alive to the necessities for prompt action. The cause of the trouble may be referred to two circumstances—the accidental admixture of vegetable refuse, and the extra accumulation of green scum, or, as it may be technically called, nostoc. Both of these conditions have been the result of a prolonged drought, for which, under existing arrangements, the authorities of course are not to blame.

The character of the water-shed of the Croton guarantees water of the best quality. Nowhere in the world are the natural conditions so well fulfilled for absolute purity. Extending over an area of eight hundred and thirty-nine miles, this water-shed is capable of supplying a city with four times the population of New York, and is practically free from all the ordinary sources of pollution in the shape of sewage, or from the contaminating influence of factories on the banks of the tributary streams.

The system of water supply is admirable, as far as it goes, and is calculated to meet all objections on ordinary occasions, but that extra emergencies are apt to arise which, under the existing engineering facilities, the authorities are not able to meet, is now quite apparent.

The question which naturally presents itself at this juncture refers to the best means which can be adopted to counterbalance, wholly or in part, the effects of any accident of a prolonged drought in future. It is hardly possible to prevent the formation of scum on drinking-water when kept for a long time in a reservoir, and although it is comforting to know that algæ are not poisonous, their presence is not calculated to add to palatability.

Again, the accidental admixture of extraneous vegetable material washed into the streams by light rains, which material, in consequence of the low level of the reservoirs, cannot be washed over the dams, will hardly explain away the anxiety for more serious contamination in future when the causes producing it may accidentally be intensified. It is not, however, sufficient to explain that unpalatable water is not unhealthy, as naturally the demand must be for pure water at all times and under all circumstances. There is in fact nothing in which the public take a greater interest, and nothing concerning which a greater effort is likely to be made in the direction of radical measures. Fortunately, the remedies for the evils complained of are not beyond our reach. The Chief Engineer of the Croton Aqueduct Department has explained in a very satisfactory manner the cause of the trouble, and has suggested a feasible plan for so increasing the engineering resources as to render similar accidents impossible.

The obvious means of counteracting the effects of a drought is to increase our reservoir capacity, not only to have enough water in store, but enough to spare for washing over our dams and getting rid of vegetable debris. The chief engineer believes that such is hardly possible at present, and suggests the construction of an extra dam higher up the Croton river, which, in his opinion, will guarantee the storing of sufficient water to meet the greatest emergency of the most protracted drought, affording the means of overflowing the dams and of "blowing out" the "dead ends" of the pipes whenever the purposes of cleansing require it.

Another suggestion which he makes in reference to the construction of an extra main to the city is worthy of serious thought. No more opportune occasion than the present could be seized by him for urging the adoption of a measure, the feasibility of which can hardly be questioned.

Of course all this will entail expense upon the city, but it is the only condition upon which the possible evils of bad drinking-water can be prevented. In view, however, of the great interests at stake, there is good reason to hope that any reasonable means which may be adopted to obviate any of the probable accidents of the future, will meet with no serious opposition. The time will come when the necessities for these improvements will be more apparent than they are even at present, but the more the subject is agitated the sooner will the public be prepared to take action in the matter.

So far, the Aqueduct Department has proved itself worthy the confidence of the people: indeed, it must be apparent to all, despite the sensational charges of

negligence in some of the newspapers, that it has done all that could have been expected of it, not only in efforts at preventing contamination, but in mitigating its effects when such prevention has been beyond the means at its control.

Reviews and Notices of Books.

ROYLE'S MANUAL OF MATERIA MEDICA AND THERAPEUTICS. Edited by JOHN HARLEY, M.D., London, F.R.C.P., F.L.S. Sixth Edition. Philadelphia: Lindsay & Blakiston. 1876. 12mo, pp. 823.

THIS is an elegant volume of over eight hundred pages, and as a manual for students, either medical or pharmaceutical, seems all that could be desired. Every page shows the painstaking labor bestowed upon it by its distinguished editor, Dr. Harley, and the many additions and alterations found in the work will but increase its usefulness, and ought to make it a standard reference for all time. As deserving of particular attention, the well-written articles on Conium, Digitalis, Belladonna, Quinine, etc., etc., are commended to the reader, and they alone will fully compensate for the small outlay required to possess this compact and masterly edition to our Materia Medica.

TRANSACTIONS OF THE AMERICAN MEDICAL ASSOCIATION. Vol. XXVI. 1875, p. 525.

THIS volume of "Transactions" has just made its appearance upon our table, nearly one year after the meeting of which it is a report. On the principle "better late than never," we congratulate the members on the early date of its publication. As there appears to be no reasonable excuse for the delay, we are called to commend the arduous labors of the Committee on Publication. As a whole, the volume is a good one, the majority of the papers being of much value, and evincing a disposition on the part of contributors to minister to the practical wants of the profession at large. The addresses are, without exception, admirable, and prove the wisdom of the change in the plan of the organization which provides for their annual delivery.

The reports of the sections are full, accurate and interesting, and form one of the principal attractions of the volume. As usual, the work is well printed, and sensibly free from typographical errors.

HINTS IN THE OBSTETRIC PROCEDURE. By WM. B. ATKINSON, M.D., Physician to the Department of Obstetrics and Diseases of Women, Girard Hospital, Philadelphia. T. K. Collins, Publisher, 705 Payne Street.

THIS small manual of about seventy-five pages, although containing nothing new, recalls to mind many valuable and generally recognized rules of practice in this branch of medicine. Frequent errors in the grammatical construction of sentences detract not a little from the merits of the book. In many places the style is awkward, and the views of the author obscurely expressed.

That "ergot becomes of value when, by the feebleness of the pains, the delivery is retarded, while the presentation is natural and the os is dilated or readily dilatable, the head still remaining high up," is a statement many will doubt, and in the practical application of which all need to exercise the greatest care.

A TREATISE ON THE DISEASES OF THE NERVOUS SYSTEM. By WILLIAM A. HAMMOND, M.D. Sixth edition. Re-written, enlarged, and improved. New York: D. Appleton & Co.

THE present is the sixth edition of this work, which, we are informed by the author, has been "re-written, improved, and enlarged." As a whole, the volume is a remarkable compilation of the literature of nervous diseases, giving a very fair idea of the field occupied by this specialty. Although it contains much, it nevertheless lacks much. The pretensions to which it lays claim of being an authority on the subjects of which it treats, makes the omissions of fact and inaccuracies of statement which are to be found throughout the volume less likely to be overlooked than would otherwise be the case. We shall refer to a few of those which have impressed themselves upon us while reading the volume. Although, for instance, the pages which treat of cerebral hemorrhage are very full, we find no mention of the fact of some importance, that when contracture sets in in the very beginning of the disease the case proves almost always fatal, and that if during the first two or three days both upper and lower extremities are paralyzed, the spinal muscles are also found paralyzed to some degree, and that there is then also slight impairment of sensation. The eyes, when conjugated deviation exists, as a rule are turned toward the seat of the lesion; hence the saying of Vulpian, who has with Prevost most ably studied that subject, "*Les yeux regardent la lesion.*" We also believe that it is very important not to make use of electricity during the first days after the onset. Duchènne, amongst others, has given ample reasons for not using it.

The history and pathology of aphasia are very complete; the cases which belong to the author are identical with those reported every day in the journals. We regret that he finds no evidence in support of the opinion that aphasia may sometimes have a reflex origin. Brown-Séquard, Ogle, Onimus, and others have given abundant proofs of the existence of reflex aphasia. Onimus especially has published, three years ago, an admirable paper on the subject.

Dr. Hammond does not think that tumors can always be diagnosticated (except syphilitic), but he omits the well-known rule that convulsions, headache, and vomiting, when associated, prove beyond doubt the presence of a tumor. Moreover, tumors when located in the immediate neighborhood of the petrous portion of the parietal bone can in almost all cases be detected, as has been shown by divers authors, and especially by Brown-Séquard.

There is next an extensive chapter on the diseases of the spinal cord, which is too much divided and subdivided, and too hypothetical. In practice it is next to impossible to recognize functional disorders of every one of the numerous columns of the cord. However, the researches of the French, English, and German physicians are very elaborately exposed. The pathology of progressive facial paralysis is very fully developed, but we do not see why Dr. Hammond ascribes the disease to lesions of the nuclei of the facial nerve, and sometimes of the trigeminus. There is certainly no analogy between the symptoms which follow recognized alterations of those nuclei and the malady under consideration.

Dr. Hammond endeavors next to explain the pathology of tetanus on experimental facts. Those facts are few, and do not prove much. The experiments of Bernard on strychnia, which are here quoted, certainly have another explanation than the one given by Ber-

nard, as shown by almost all those who have experimented with the drug.

A parallel, however, drawn between the pathological anatomy of tetanus and hydrophobia would perhaps tend to show how insecure it is to be positive about anything in nervous diseases. Hydrophobia is as yet a most obscure affection, and since the researches of Meynert and Clifford Allbutt there has been nothing original added to our knowledge. We are unwilling to suppose that additional observation in the same direction with Clifford Allbutt would tend to give any appearance of certainty to his hypothesis, because the anatomical changes noticed are common to all diseases where death has come on by asphyxia after paroxysms of long duration.

That hydrophobia is communicated by saliva is very improbable, if recent experiments of some distinguished French scientists are accurate. The affection, although mostly fatal, has been cured in some instances.

Dr. Hammond seems to us to have been very felicitous with his cases of locomotor ataxia, as he reports six or seven cures. We have always heard of temporary relief, but never of a cure. The treatment advised by Dr. Hammond, in his hands proves so much more efficient than with his European *confrères*, that only a difference in the lethality of the disease, due to climatic influence, can explain it.

There is also an inaccurracy in the statement of Dr. Hammond that epilepsy is due sometimes to anæmia of the brain, and sometimes to congestion. The theory of anæmia has been pretty generally accepted since the labors of Brown-Séquard, but that congestion also does give rise to epilepsy is not so generally admitted. Dr. Hammond states that nitrite of amyl puts off an attack of epilepsy, by causing dilatation of the vessels of the brain. Now it is a fact that that substance *causes* congestion of the brain, but it is a fact also that epileptic fits never follow its administration, which we ought to expect if the congestive theory were true. That the process of epilepsy is somewhat similar with that of sleep cannot be admitted, except as far as the onset is concerned, even if the theory of sleep advanced by Durham, and since advocated by Dr. Hammond, was not seriously opposed by a host of physiologists, and lately by Vulpian. We take the opportunity to point to the learned author the excellent work of Dr. Magnan on alcoholism, as bearing upon epilepsy and kindred diseases. In conclusion, we would refer in passing to a matter of treatment.

It is very necessary, we believe, that the actual cautery should be applied without previously anæsthetizing the parts with ether spray. As suggested by Dr. Hammond, there is no necessity to burn the teguments, but only to touch them slightly with the iron heated to whiteness. Such being the case, it becomes obvious that anæsthesia can but prevent the effect of the application. Moreover, we think that the instrument is very useful in *all* cases of contractures and inflammation of the nervous centres, chronic or acute.

AIDS TO ANATOMY. By GEORGE BROWN, M.R.C.S., L.S.A., late Demonstrator of Anatomy at Westminster Hospital Medical College, etc., etc. London, Dublin, Edinburgh, Glasgow.

THIS little manual is a reprint of anatomical memoranda published in *The Students' Journal and Hospital Gazette*. It is divided into XLV. sections, each of which contains an enumeration of the anatomical parts embraced by the triangle, space, region, nerve trunk, etc., under consideration. It is convenient for reference and study.

CYCLOPÆDIA OF THE PRACTICE OF MEDICINE. Edited by DR. H. VON ZIEMSSEN. VOL. V. *Diseases of the Respiratory Organs.* By Prof. Juergensen of Tübingen; Prof. Hertz of Amsterdam; Prof. Ruehle of Bonn, and Prof. Rindfleisch of Würtzburg. Albert H. Buck, M.D., Editor of American Edition. 8vo, pp. 712. New York: Wm. Wood & Co. 1875.

THE names of the contributors to this volume justified the expectation that it would prove to be one of the best of the series, an expectation which is abundantly met by the reality. The selection of Prof. Juergensen to furnish a treatise on pneumonia, is as appropriate as that of Liebermeister for typhoid fever; and the gifted young author has done himself additional credit by the able manner in which he handles his subject.

The first paper is on croupous pneumonia. After a brief outline of the history of the disease and due study of its etiology, the writer passes to its pathology and morbid anatomy. Under the latter head we find the following definition: "croupous pneumonia is, anatomically considered, an acute inflammation of the alveoli and bronchioles, in which a fibrinous exudation is poured out upon the free surface of the mucous membrane and there coagulates." The author, however, does not commit himself to an opinion as to the origin of the different constituents of the exudation, although giving, at considerable length, the views of other writers on this point.

As regards caseation of the exudation, which is so stoutly denied by Buhl, who avers that phthisis or cirrhosis never follows croupous pneumonia, Juergensen very appropriately calls attention to the fact that Buhl is not a practising physician, and that clinical experience proves beyond doubt that both these results may occur, an assertion in which he will be borne out by many observing practitioners. The analysis of individual symptoms, and the questions of physical examination, complications, terminations and diagnosis, are all admirably, and, at the same time, concisely set forth.

In entering upon the treatment of the disease, certain queries are propounded and are thus answered: "Croupous pneumonia is a constitutional disease, and is not dependent upon a local cause. The pulmonary inflammation is merely the chief symptom, and the morbid phenomena are not due to the local affection. The hypothesis of a morbific cause is indispensable. Croupous pneumonia belongs to the group of infectious diseases." (Of course our readers will not understand infectious to mean contagious.)

We cannot enter upon the author's defence of these positions. Merely to state them is enough to attract attention and arouse interest. Following certain principles which are laid down, rather than any routine practice, it appears that we have to do almost nothing for about eighty per cent. of the cases of croupous pneumonia, and to employ the most active treatment in the remaining twenty. Danger threatens the heart principally, death resulting from insufficiency of the heart. The arguments to sustain this proposition are conclusive, but cannot, of course, be given within the narrow limits of such a notice as this. The two objective points of treatment, therefore, are first, the prevention of cardiac exhaustion; and second, its control, if already existing. The most important means of prevention is to combat the fever, which may be best accomplished by means of cold baths and quinine.

When cardiac insufficiency has intervened, stimulation by means of wine, liquor, camphor, musk, etc., is advocated. All the author's views are abundantly

fortified by anatomical and clinical facts, and what seems to us candid and logical reasoning.

The subject of catarrhal pneumonia is much more briefly disposed of. We are told at the start, that this form is always secondary, never originating primarily in the alveoli, and being usually preceded by an inflammation of the bronchial mucous membrane. In the etiology of the disease, those conditions and diseases which predispose to or induce bronchial catarrh naturally play a prominent part. The pathology and anatomical changes are briefly given. In analyzing the symptoms, it is first of all premised that catarrhal pneumonia has no regular type of fever. It is shown, also, that collapse of the lung plays a very prominent rôle in the early history of the disease.

The author admits that "the physical diagnosis of an acute and not very extensive catarrhal pneumonia belongs among the most difficult tasks in this department of our science." Throughout the paper it is insisted that bronchitis is the essential pre-requisite of this affection.

The section on Diagnosis is quite full and satisfactory.

As in croupous pneumonia, cardiac insufficiency was announced as the main cause of death; so, in the catarrhal form, *respiratory* insufficiency is assigned the first rank among the fatal agencies. In the matter of prophylaxis we must guard, first against catarrh; secondly, against pneumonia when catarrh exists. After catarrhal pneumonia is developed, the main point to aim at is the prevention of pulmonary collapse. In addition to some other means detailed, special stress is laid on the use of baths of a moderate temperature followed by cold affusions, the effect of the latter being to excite powerful and deep inspiratory movements, and thus distend every portion of the lungs. After recovery from pneumonia a *residence* in the country is recommended, as well as means for the most complete development of the respiratory muscles.

Hypostatic processes in the lungs and pneumonia from embolism are disposed of quite briefly, but with the thoroughness which is so characteristic of this writer.

Prof. Hertz, of Amsterdam, devotes twenty-five pages to Anæmia, Hyperæmia and Œdema of the Lungs, without telling us anything new. He is much better on the subject of Pulmonary Hemorrhages, the sections on etiology and pathology being especially clear and thorough. Prof. Hertz does not agree with F. von Niemeyer in the opinion that bronchial hemorrhage is often a cause of phthisis in previously healthy lungs. He would be more willing to believe that previous disease of the lungs had escaped detection. His differential diagnosis between hæmatemesis, bronchial hemorrhage, and the blood raised from a hemorrhagic infarction is plain and sufficiently definite. In the treatment of hæmoptysis, blood-letting may occasionally be applicable; in case of anæmia, iron internally; repose, narcotics, cold externally, inhalations of a solution of perchloride of iron, the watery extract of ergot hypodermically: all these are recommended. The use of emetics is not advised.

Twenty-two pages are devoted to the consideration of Pulmonary Atelectasis, Atrophy and Hypertrophy. Then follows a subject of far more general interest, viz.: Emphysema. The etiology and mode of development of this affection are discussed in an exceedingly able and interesting manner. Under the head of treatment, the method of placing patients in pneumatic cabinets and the inhalation of condensed or rarefied air by means of Waldenburg's apparatus, are referred to. For the benefit of our own readers the American Editor has very considerately added a description and plate of Waldenburg's apparatus in a foot-note.

Gangrene of the lung and New-growths in the lung are treated of in separate chapters. Then follows a very interesting chapter on New-growths in the Mediastinum, and Prof. Hertz's contribution closes with a few pages on Parasites of the lungs.

Prof. Ruehle, of Bonn, contributes a valuable article on Pulmonary Consumption, and another on Acute Miliary Tuberculosis; while Prof. Rindfleisch, of Würtzburg, closes the volume with a paper on Chronic and Acute Tuberculosis, including Pulmonary Phthisis. This seems at first sight a singular arrangement, but appears more natural when we find Ruehle treating particularly of the clinical aspect of consumption, while Rindfleisch confines himself exclusively to the pathology and morbid anatomy of the subject.

In his introductory remarks, Prof. Ruehle, alluding to the recent tendency almost to deny the existence of such a thing as tubercle, thinks this question has been left too exclusively in the hands of the pathological anatomists, and that practical pathologists and men of large clinical experience should be heard from.

An interesting point is brought up and discussed by both Ruehle and Rindfleisch, viz.: Why the apices of the lungs are the first seat of phthisis. The causes are purely mechanical, depending on obstacles to the free expansion of these parts and of the circulation of blood through them. Ruehle considers that croupous pneumonia very rarely leads directly to consumption, but is more likely to, when it attacks the upper lobes. Referring to the fact that catarrhal pneumonia is regarded as a frequent forerunner of pulmonary consumption, he says this may perhaps appear justified from an anatomical standpoint, but cannot be maintained from a clinical point of view. Like Hertz, he opposes Niemeyer's idea that bronchial hemorrhage is a frequent cause of phthisis.

In the analysis of individual symptoms he lays a good deal of stress on smallness of the chest, atrophy of the inspiratory muscles, small antero-posterior measurement of the thorax, and defective or unequal excursions of the upper ribs.

Under the head of diagnosis he points out the fact that acute miliary tuberculosis is a special affection which cannot be classed with pulmonary consumption; and he denies the existence of chronic miliary tuberculosis. He considers that, so far as we know at present, the different varieties of phthisis depend upon three forms of pulmonary lesions, viz.: first, the simple chronic pneumonia of the apex; second, broncho-pneumonia, in which the first change is the formation of clusters of nodular foci, which excite inflammation about them, etc., etc.; and third, morbid processes which begin in the bronchi, there producing inflammatory infiltration, caseation, etc. The sections on diagnosis, course and terminations, and treatment, are short and good, offering nothing that is specially new.

Acute miliary tuberculosis is assigned a separate chapter because the author believes it to be distinct from phthisis. We know of but one cause for the formation of miliary tubercle, *i. e.* absorption of caseous matter. This may arise from caseous lymphatic or bronchial glands; hence, after measles, etc.; also from caries of bone and other tissues. Pulmonary consumption is therefore only one of its exciting causes, though no doubt the most frequent one. On the morbid anatomy of this affection he quotes Rokitansky's words, as they appeared in the first edition of his Handbook, in 1842.

We have not the time left to give any such notice as it deserves to the closing chapter on chronic and acute tuberculosis, by Prof. Rindfleisch. It is a masterly effort, reconciling a good deal that has seemed to be antagonistic in the different views on this subject. The author recedes from much that he formerly held true, with regard to the origin of phthisis in pneumonia and bronchitis. A few years ago we were almost all carried away by the confidence and enthusiasm with which Niemeyer advanced his doctrines, based, as they seemed to be, on the anatomical investigations of Virchow and others. But many of us have gradually receded from this ground, as we have found that it failed to agree with the facts of our daily experience. We shall, therefore, be the more ready to accept the prominence again given to tubercle in the article before us, the rather as it is also effectively supported by anatomical demonstrations. We earnestly commend this paper of Rindfleisch to the careful study of all thinking men in the profession.

As before stated, Vol. V. of the Cyclopædia is one of the best, if not the best of the series.

MICRO-PHOTOGRAPHS IN HISTOLOGY. By CARL SEILER, M.D. Nos. 1 and 2. Philadelphia: J. H. Coates & Co.

THE title of this work is a misnomer. It should be *Photo-micrographs*, etc. A *micro-photograph* is a minute photo, such as are seen in watch-charms, knife-handles, etc., while a photo-micrograph is the photographic delineation of a microscopic object. The design of the present work is to illustrate subjects in normal and pathological histology by means of photographs of objects previously enlarged by the microscope. The photographic negative thus obtained is used as a basis for the photo-mechanical process by which the illustrations are produced. The idea of delineating microscopical appearances by means of photography is a good one, as it substitutes truthful representations for the fanciful distortions with which the draughtsman usually furnishes us. No one who has studied the superb photo-micrographs emanating from the Army Medical Museum can doubt their superiority over woodcuts and lithographs as a means of conveying *accurate* information concerning the appearances observed. In work of this kind, however, there are certain essentials which must be considered if success is to be obtained. In the first place, the subjects must be judiciously selected; second, photographs must be well made; third, the mechanical process by which they are reproduced should be the best attainable. By these criteria we must judge the present work.

Plate I., representing a *section of skin*, is good. Pl. II., *Epithelioma*, is badly selected, insomuch as in it the special peculiarities of epithelioma (cell-stratifications) are not represented. Pl. III., *Pavement epithelium*, is excellent. Pl. IV., *Endothelium*, was not in focus. Pl. V., *Elastic connective tissue*, is wretched. Pl. VI., *Scirrhus*, not well selected. Pl. VII., *Non-elastic tissue*, and Pl. VIII., *Connective-tissue corpuscles*, are superb.

The mechanical process employed is not a good one. The high lights are all studded with minute points which gives a granular aspect where there should be none. Some better process should be employed in future issues.

On the whole, Dr. Seiler's work is good, and should be encouraged, and if avoidable defects are remedied, he will doubtless succeed in giving to the profession a work of immense value. At present America stands at the head in the matter of photo-micrography, the work of Col. Woodward, of Washington, and of Prof. Arnold, of this city, being vastly superior to anything of the sort as yet produced in Europe.

Reports of Societies.

AMERICAN MEDICAL ASSOCIATION.

SECTION OF STATE MEDICINE AND PUBLIC HYGIENE.

CONTAMINATION OF DRINKING-WATER AND MILK.

THIS Section met on Tuesday afternoon, June 6th, Chairman, Dr. R. C. KEDZIE, of Michigan; Secretary, Dr. EZRA M. HUNT, of New Jersey. The chairman read a report, and proposed to the Association the consideration of the question, whether a subject should be annually assigned to the Section, and if so, that the Section should choose the subject each year. Among other matters, the importance of State Boards was argued, and their value illustrated by the benefits of a stringent inspection law as to illuminating oils in his own State, etc. He then offered a report on the waters of Michigan, public water-works, contamination of water by grave-yards and fæcal matter, the powers of the soil as a filter, milk as a vehicle of disease, as affected by the quality of the water, etc. He also read a paper on the same subject by Dr. Evarts of Minnesota.

DR. HENRY HARTSHORNE was particularly struck with the statements these papers contained in regard to milk and its agency in the production of disease. He did not think that disease could be transmitted through a mile of soil, as had been stated; there might be other and local causes to produce it. The soil would be more likely to act as a filter, and thus detain the germs of disease.

DR. BELL did not think with Dr. H. that the case cited destroyed the germ theory, for the germs, which are invisible, may not always be thoroughly filtered, even in passing through so great a distance. In regard to milk, the richest specimen of it may be diseased. A swill-fed cow will give milk richer in oil globules than one fed on wholesome food; yet medical practitioners know that it is not wholesome. He alluded to the effect of severe shock, over-heating, etc., on the milk. Sanitary supervision of milk is incomplete, unless it extends beyond the physical condition of the cow, and includes her keeping and food as well, and the place in which the milk is kept.

DR. KEDZIE also argued, that germs could not be perfectly separated by filtration; fine foreign particles could not be prevented from passing through.

DR. JONES, of Illinois, thought that boards of health were the only bodies that could grasp the broad subject of the milk supply. Even when a child is restricted to the milk of an apparently healthy cow, there may be something injurious to the child, as in a case cited, in which a child's nutrition suffered greatly, and was only restored by the death of the cow. The great mortality among children was largely due to the diseased condition of the milk.

On motion, the papers were referred for publication.

PREVENTION OF MALARIAL FEVERS.

DR. JOSEPH WILSON, U. S. Navy, then presented a paper on "Facts and Figures as to our Means of Preventing Malarial Fevers." He illustrated, from naval experience chiefly, his view that malaria never acts except at night. He inquired how far malaria could be carried, depending on its amount and other favorable or unfavorable conditions. The planting of pine-trees was good as a preventive.

Dr. Bell had not been able to say as emphatically as Dr. Wilson, that it was only at night that the malarial influence is potent enough to be dangerous, although he knew of no instance to constitute an exception to the theory. The same was true of yellow fever, so far as his observation extended. He alluded to the importance in the navy of keeping the proper distance from the shore, say a mile or two, there being no case on record where any person within two miles of the shore has ever contracted any disease peculiar to a locality, the water absorbing or interrupting the communication of the poison. In instances cited by him from naval experience, prophylactics were not used. At Vera Cruz he advised the use of whiskey, and hung up blankets to break the current of air. Bars were placed to come down over their hammocks, while sleeping on deck.

Dr. Hartshorne thought it safe to remain on shore in malarious districts, not only while the sun was far above the horizon, but even as late as sundown.

Dr. Wilson stated that at Charleston, where his early experience was derived, children would go through a severe storm to reach their homes by day, rather than through a malarious night air. The Chinese, even in the dangerous rice swamps of China, are almost proof against malaria, because they take good care to push off in their scows to a broad part of the channel before night. He considered half a mile from shore the extreme limit that malaria can be conveyed. In the navy they used prophylactics, quinine in large doses, and mosquito bars.

The paper was on motion referred to the Committee on Publication.

CLIMATOLOGY OF MINNESOTA.

Dr. Staples read a paper on the second day, on the Climatology of Minnesota as related to Pulmonary Diseases, which was similarly referred. A report on the Water Supply of Virginia, by Professor Cabell, was also referred.

SOCIAL ASPECTS OF THE ALCOHOL QUESTION.

Dr. May, of Pennsylvania, read a paper on the "Social Aspects of the Alcohol Question."

Dr. Ezra M. Hunt said the general view now taken was that alcohol's great offence was that it checks the tissue metamorphosis. He was not willing to dismiss the whole subject, of whether it is food or medicine, by saying that no one now claims that it is not food. Beale certainly takes this latter ground, and says it does check the tissue metamorphosis. He did not agree with the writer that food and stimulants are synonymous terms, or that if alcohol acted as a stimulant it always did good, and if as a narcotic it did harm, or that its stimulant effect could be told by the flushed face or its action on the kidney.

Dr. May said he drew a distinct line between large and small doses.

Dr. Hunt said the question was whether every dose was not a large one if it flushed the face.

Dr. Comings thought that alcohol was not an agent that private families could safely keep in their houses. He denied that it was a food any more than tobacco or opium. It is a narcotic, acting on the terminal nerves, paralyzing them, and suspending secretion, absorption, and other nutritive changes. A man under the influence of opium or tobacco can do without food longer than one who has not taken those substances, because normal changes are suspended, not because tobacco or opium are nourishing. In typhoid fever, alcohol was, in his view, only necessary when the blood is driven to the centre.

Dr. May said alcohol was used everywhere in hospitals in typhoid fever. As to the nutritive qualities of alcohol, the fact had been separately established by two German physiologists in their experiments on animals.

The paper was considered rather a popular exposition of the gentleman's theory, than as coming properly before the Section, belonging rather to a hygiene association.

Dr. Comings offered resolutions coinciding with the opinion expressed by the Association of Medical Superintendents of Insane Asylums: 1. That inebriates should not be sent to the same institution as the insane; 2. That inebriety being both a disease and a vice, special treatment in institutions adapted to the purpose is required for the inebriate, and it is the imperative duty of each commonwealth to establish and maintain public institutions for the treatment of inebriety.

Dr. Hubbard offered resolutions to the effect: 1. That a person, forming a habit of continual or frequent drinking of alcoholic beverages to intoxication, should be held to be of unsound mind; 2. That a suitable name for such intoxication is alcoholic insanity; 3. That it can be treated only in institutions especially established for that purpose; 4. That the two leading characteristics of such institutions should be restraint and profitable industry.

Dr. Comings said it required a little stretch of conscience to sign a certificate that a man was insane merely because of habits of alcoholic intoxication, but there is no other institution in which he can be treated except the insane asylum. From various official State and Society appointments, he had been led to inquire more fully in regard to this matter; he was anxious that this Association should add its voice. He referred to the predisposition of some persons to intoxication, even from moderate drinking.

Dr. Hubbard was anxious that the sentiment of the Association should be brought to bear on the Indiana Legislature to establish an institution for inebriates.

Dr. Hartshorne thought the first series of resolutions too sweeping, in stating that every one taking alcohol to excess must be insane.

Dr. Billings thought the phraseology as to "insanity being both a vice and a disease," tautological. The vice here is the disease.

Dr. Comings said the clerical profession treated inebriety solely as a vice, not recognizing it as a disease. The medical profession have not the means of treating it morally. Better to consider it both a vice and a disease, and let both professions attend to its proper treatment.

The resolutions of Dr. Comings were adopted. A paper by Dr. Dennison, on Colorado as a Climate for Consumptives, was referred to Dr. Toner, as a Committee of one, to report to the Section at its next session.

PUBLIC HEALTH COMMISSION.

Dr. Toner then read the report of the Committee on establishing a Public Health Commission for the United States, which, on motion of Dr. Billings, was made the special order for the next day.

On the third day, Dr. Billings stated that in his view the Association should not meddle with the matter at this time.

Dr. Harris, of New York, while agreeing with him, was anxious that the Committee's valuable report should be fully discussed. The three National Medical Societies are doing very much in this direction in their inquiries as to quarantine, prevalence of epidemics,

etc. The question is whether it would be desirable just at this time to add a National Health Council. He alluded to the difficulties in the States of bringing the popular intelligence and the Legislatures up to the standard, and to do the good work now in progress of accomplishment in improvement of water supplies, abatement of nuisances, etc., and contended that it was very important that this State work should continue to greater perfection before national systematized work of the same kind should be undertaken. Only seven States are as yet accomplishing anything of importance, without being hampered in some way or other. In Pennsylvania and New York it seems as if the time had hardly come yet when the Health Boards of the great cities would cheerfully unite with each other and with the physicians to secure a State Board.

Dr. Billings thought a bill for the establishment of a National Board, as reported by the Committee, would come more appropriately from the American Public Health Association, whose proceedings and discussions were intended for all. We must impress on our legislators the importance of sanitary measures, their good results, economic value, etc., but it is not the part of physicians and scientific men assembled in the National Medical Association to do so. The work of the latter was of a more special character, intended for a special class, physicians, and did not rightly include an attempt to lay out plans of legislation. The physician is especially interested in matters connected with the public health, because he sees more than any one else the bad results of want of proper sanitary measures. The information necessary for proper State legislation and statistics has to be furnished by the physician.

Dr. Bowditch thought it would be unwise to suggest a bill to Congress, until public opinion was thoroughly educated and State Boards were generally organized. He thought, however, that some good might be done by bringing a general statement of the advisability of a future organization before Congress, though not in the shape proposed by the Committee.

Dr. Toner, one of the Committee, did not insist on the form offered. Nearly every measure going before Congress has a bill appended. This one would show that body that legislation would be expected from it on that subject. He favored the publication of the bill in the Transactions, and its being reported to Congress, so as to attract public attention. We had better, as an association, lead than follow.

Dr. Harris said that before the next census, Congress would have to do something to secure a better census of the public health. He alluded to the various advantages to be derived from a central body, such as a National Board. This Section might itself originate a certain class of reports to be brought before every Congress and Legislature. Quarantine and other questions must be made national questions altogether. The South and West are very anxious that Congress should act; but he thought little good could result from asking Congress to act now. In New York an organization had been secured which in a few years will be perfected, so far as water-supply and drainage especially are concerned.

Dr. Hunt did not think it was necessary to have all State work perfected before going to Congress. He questioned whether they should carry the proposed bill to that body, but influence should be brought to bear on members of Congress individually. It would be well to bring to the attention of Congress the fact of defects existing in the method of taking the medical census, in the interest of universal health. They might act on this, when they might refuse to do so with a bill covering a vast area. We may get special legislation as exigencies may arise, such as yellow fever, when we cannot obtain general laws. Such had been his experience in New Jersey, where, although met with refusal as to the establishment of a State Board, the mere agitation had procured the institution of a Sanitary Association, the aid of the public press, and the education of the popular mind.

Dr. Foster thought a bill passed before the public were thoroughly educated to its necessity would be a dead letter. The States should be in advance of any national action, although Congress might be invoked on special points, as already suggested.

Dr. Dowell, of Texas, spoke of the favorable effects of agitation in Texas.

Dr. Hartshorne suggested the advisability of appointing a Committee of Conference on the subject of a National Health Bureau, with power to act according to circumstances.

Dr. Lee, of Pennsylvania, spoke of the difficulties of legislation in that State. He thought that, as physicians urging the necessity of national legislation, we should not be too modest. A petition to Congress, with an accompanying bill, might awaken that body to the importance of the subject.

Dr. Bowditch offered the following: *Resolved*, that the Section recommends that the following vote be passed by the Association: 1. That the American Medical Association earnestly urges upon Congress to devise some plan whereby a national sanitary organization shall, as soon as possible, be established: 2. That the above vote be forwarded to Congress by the proper officer of the Association.

Dr. Billings inquired whether any action had ever been taken by this Association with regard to the formation of State Boards.

Dr. Bowditch asked whether any report had been made by the Secretary of the Association as to the appeal made by its officers annually to the States for the establishment of State Boards.

Dr. Toner did not think there were more than two states indifferent to the subject: in less than five years, he predicted, a majority of the States would have State Boards of Health.

Dr. Hartshorne reminded the members that the very object in having this Section organized at first was to urge this matter of public health. Its duty was to watch the auspicious time for action, and not be too precipitate.

A motion of Dr. Billings to receive the report and discharge the Committee was adopted.

Dr. Bowditch's resolutions being in order, Dr. Hunt suggested, as a modification of the first resolution, that the Association urges upon Congress the devising of some plan whereby the National Government can secure such information bearing upon the health of the nation as shall be of service in its promotion. The resolutions were adopted.

Dr. Toner, as committee on Dr. Dennison's paper, said it was a little rose-colored in favor of Colorado for consumptives, but a valuable report; which, on motion, was referred to the Committee of Publication.

The report of Dr. Linthicum, of Arkansas, on the water-supply was presented and similarly referred. Dr. Benjamin Lee, of Pennsylvania, then read a paper on the "Trials and Triumphs of the Sanitarian."

On motion of Dr. Harris the Chairman and Secretary were directed to prepare a concise statement of the particular subjects upon which action of the National Government is necessary, and a simple resumé of the points and reasons showing the nature of the work which needs to be entrusted to the State Boards of

Health; such statement to be presented to the next annual meeting of the Section.

After listening to a paper on Yellow Fever, by DR. DOWELL, of Texas, the Section adjourned *sine die*.

Correspondence.

SALICYLIC ACID IN RHEUMATISM.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—At the time of the appearance in the MEDICAL RECORD of the first article relating to the use of salicylic acid in acute inflammatory rheumatism, I had in charge a patient suffering with that "most unkindest" affection.

Mr. M., aged 28 years, a healthy working man, of good habits, and employed as janitor in the public school buildings, was seized suddenly and rather violently on the morning of April 18. The attack was ushered in with the usual symptoms; and at the time I concluded to try the salicylic acid the disease was pursuing the even tenor of its way, having reached the eleventh day. At this time the articulations in the limbs and upper extremities were greatly swollen, intensely red, and very painful. The patient was helpless, and it was with great difficulty that he could be moved.

A vigorous alkaline treatment, with quinine and colchicum during the latter part of the time, had resulted in no apparent benefit. Perspiration was profuse, the urine alkaline in its reaction, and the patient very much prostrated. The pain was intense and constant, except when the patient was under the influence of an anodyne. I ordered the acid given in five-grain doses every hour, the vehicle being equal parts of glycerine and water. After the sixth dose I noticed a marked reduction in temperature. The extremities became cold, the circulation thready, and there seemed to be an entire loss of memory. These conditions rapidly gave way to stimulation, however, and in fifteen hours after the administration of the first dose the pain and swelling had entirely disappeared. On the second day after beginning the acid treatment the patient took his dinner at the table, being able to feed himself. Treatment was continued for two days longer, the doses being given at intervals of three hours. The patient made a good recovery, there being no return of the disease.

On May 17 another case of equal interest to me came under my observation. Mr. E., aged 22, a plasterer by trade, was taken with acute inflammatory rheumatism, affecting the upper extremities. Two years ago this patient had a similar attack, and the disease gradually extended until most of the articulations in the body were affected. The usual treatment was given, but the case continued twenty-six days, and I had but negative evidence that my treatment had been of any avail. When I called to see him during his last attack I was met with: "Doctor, I'm gone up again for twenty-six days." He was suffering intensely, and I at once gave him ¼ gr. morphia, subcutaneously, after which I ordered the acid as before. In this case the reduction of temperature was not so marked, and there was an absence of the unpleasant symptoms noted in the first case. The result, however, was all that could be desired. In twenty hours the pain and swelling had disappeared, and in one week the patient was pursuing his usual avocation. In this case no medicine whatever was given except acid—save the ¼ gr. morphia used subcutaneously.

GEO. O. MORGRIDGE, M.D.

WEST LIBERTY, IOWA, July 7, 1876.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from August 6th to August 12th, 1876.

GREENLEAF, C. R., Surgeon. Granted leave of absence for one month, with permission to apply for an extension of one month. S. O. 115, Dept. of the South, Aug. 8, '76.

HAPPERSETT, J. C. G., Surgeon. To report to the Commanding General Mil. Div. of the Atlantic, for assignment to duty. S. O. 162, A. G. O., Aug. 9, '76.

Medical Items and News.

CONTAGIOUS DISEASES.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending August 12, 1876.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.

CHOLERA IN CATS.—A disease resembling cholera has been epidemic among cats at Delhi.

CHOLERA.—Outbreaks of cholera are reported from various parts of India.

THE PLAGUE is reported to have ceased in all the localities where it has recently been prevalent.

SURGEON TO THE POPE.—Dr. Ceccarelli has been appointed "secret surgeon" to the Pope, a place left vacant by the death of Dr. Vincenzo Sartori.

AN OLD UNIVERSITY.—The University of Upsala (Sweden) will celebrate in September of next year the four hundredth anniversary of its existence.

WILFUL SPREAD OF INFECTIOUS DISEASE.—A woman was recently arrested and fined for removing her child from the London Fever Hospital before the infectious period of scarlet fever, from which she had been suffering, had passed away, or the clothes had been properly disinfected.

CHLORAL PLASTER.—For neuralgia, rheumatic pains, etc., use the ordinary emplastrum roborans, and powder it with the chloral. Apply the plaster to the affected part, and leave it from twenty-four to forty-eight hours. When taken off, the skin is found studded with vesicles; these are to be pricked with a pin, followed by a dressing with simple ointment. The pain vanishes long before the vesicles are dried up.—*Lancet.*

Original Communications.

SCARLATINAL HÆMATURIA.

A CASE WITH REMARKS.

By V. P. GIBNEY, A.M., M.D.,

ASSISTANT PHYSICIAN TO THE HOSPITAL FOR THE RUPTURED AND CRIPPLED, NEW YORK.

RENAL hemorrhage occurs so frequently that, unless it occur in excess, no alarm need be excited on the part either of the attending physician or the patient. We not infrequently meet with many cases of acute desquamative nephritis wherein the urine contains blood and blood-casts; still, this condition of affairs is not the preponderating sign of the disease. Albumen is found in abundance, œdema and anasarca are present, and occasionally uræmia becomes an alarming feature. With such we are all familiar, and a mere reference will suffice.

Trousseau* says that, in point of fact, hæmaturia is a rather common occurrence, but frequently escapes observation. The admixture of acids with the urine gives it a blackish color, *i.e.*, when the blood is pure. The text-books in general devote a brief mention to the subject, all concurring in its insignificance. Dr. Loomis† says "the bleeding which accompanies inflammation of the kidneys in the infectious diseases is never severe or constant."

Hæmaturia is symptomatic of purpura, scurvy, cholera, cancer, the eruptive fevers, malarial poisoning, mental emotion, etc. The points in differential diagnosis need not occupy time in this connection. Suffice it to say, however, that any one with a history of the case and an ordinary microscope need not go far astray. When it exists as a sequel, or complication even, of scarlatina, albumen will, as a rule, be present, and the brownish hue given to the deposit on the application of heat or nitric acid will generally decide the question.

From the following history and a reference to the current literature on the subject, I hope to deduce some practical conclusions.

CASE.—B. M., æt. seven years, female, admitted to the Hospital for the Ruptured and Crippled, May 8, 1875. The disease for which she came under treatment was morbus coxarius, four months' standing, little deformity as yet having arisen. She had been in the Roosevelt Hospital two or three months for the same disease.

On *June 18th*, same year, a rose colored eruption appeared over the neck, shoulders, and extremities. This, taken in connection with constitutional disturbance twenty-four hours previously, and a concomitant redness of the fauces, the character of the eruption, etc., made the diagnosis of scarlatina simplex comparatively easy. Ten days later, the characteristic desquamation presented, no complication having arisen during the attack. In fact, the case proved an exceedingly mild one, and for this reason we watched the more closely for sequelæ.

July 17th, twenty-nine days from the beginning, the child manifested slight indisposition, for which a cathartic was ordered, and directions were given the nurse to procure a specimen of urine for examination. This was not procured until the following day, when the color was found of a dingy raspberry red, the specific gravity 1020, albumen about fifty per cent., a deposit, after standing a short while, of blood, while the microscope revealed fibrinous and blood-casts, with red and white blood corpuscles in great numbers scattered throughout the field.

There was no œdema anywhere to be found. One drop of the oleum Tiglii produced a copious evacuation, and as the kidneys were acting fairly, and no urgent indications were present, the treatment adopted was expectant.

July 20th.—On qualitative analysis, the urine gave the same results as obtained at last examination, with the exception of a less proportion of albumen.

July 22d.—Specific gravity 1036; light precipitate of albumen; blood corpuscles abundant. The quantity of urine voided to-day, scanty and being still more scanty on the following day, the infusion of digitalis was ordered in drachm doses every two hours, and mustard sinapisms were applied over the region of the kidneys.

July 24th.—Nausea and vomiting; profuse alvine evacuations, highly colored, with bloody urine.

July 25th.—Urine deep red; specific gravity 1023; albumen 15 per cent.; blood casts. A.M., pulse slow and intermitting at every tenth beat; digitalis discontinued; brandy and milk rejected by the stomach. M., no intermittence of pulse; stomach retains the milk and brandy, but nothing else. P.M., pulse regular; three evacuations.

July 26th.—Symptoms all denote improvement.

July 28th.—Quantity of urine in twenty-four hours, six ounces; specific gravity 1006; albumen 25 per cent.; field of the microscope full of blood corpuscles; an attack of dysentery through the night, with tenderness on pressure over the iliac region this morning. Digitalis renewed.

July 29th.—Dysentery arrested spontaneously.

July 30th.—Pulse intermits at second beat; as yet no sign of œdema; no derangement of any of the special senses; urine still bloody and albuminous.

July 31st.—Pulse still intermittent; digitalis three times a day, instead of every two hours; the milk and brandy, which was begun on the 25th, has been continued.

Aug. 6th.—Since the 31st ult. the patient has been steadily improving, that is, eats her food with a greater relish, passes a larger quantity of urine, which, however, is still highly colored with blood, and is gaining strength, although greatly emaciated from the protracted illness. May be considered as convalescing.

This morning, forty-nine days from the invasion of the scarlatina, there is noticed for the first time a slight otorrhœa, left side. There has been no otalgia or other symptom of otitis; no otoscopic examination was made to detect the suspicious prominence of the membrana tympani, the importance of which we fully realized, and our only excuse for not doing so was the alarming hæmaturia and the absence of any symptoms calling attention to the ear.

August 10th.—The amount of blood in the urine evidently on the decrease.

August 13th.—Nausea and drowsiness this afternoon, while the vital signs are normal. Mustard pediluvium ordered.

August 14th.—The symptoms of yesterday are absent, and the patient is much better.

August 18th.—Still slowly improving; the otorrhœa has ceased, and the otitis, if such existed, has given rise to no inconvenience whatever.

August 28th.—One or two recent examinations of

* Clinical Medicine, vol. i, p. 152.

† Diseases of the Respiratory Organs, Heart and Kidneys, p. 419.

the urine have failed to detect any albumen or blood, and the disease is regarded as arrested, while a tedious convalescence is expected.

With reference to what bearing the vital signs may have on the subject, I have to say that the thermometer was used when the hæmaturia first appeared, and several days subsequently. No elevation of temperature beyond 99° being found, I made no record in my notes, but remember the circumstances sufficiently well to add this by way of postscript. The pulse I watched while administering the digitalis, and from neither pulse nor temperature, nor yet from the appearance of the child as seen two and three times daily, did I find any evidence of febrile disturbance worthy of attention. In fact, I wondered at its absence.

January 14, 1876.—Since the date of last note, not an untoward symptom has arisen. The strength has been slowly returning, and now she is a healthy-looking girl, muscles firm and well developed. Tonics and stimulants have been employed during the past three months.

At this time, also, no evidence of hip-joint disease can be detected, save a perceptible halt in her gait, and even this she can obviate when she makes an effort to that effect. There is no resistance to motion in any direction.

May 23*d*.—Discharged, cured of the joint disease—a spontaneous cure having been effected. There had been no recurrence of the hæmaturia. An attack of parotitis during the latter part of March gave rise to no complications or sequelæ. A fall on the fifteenth of May induced a certain amount of stiffness about the hip-joint, but two or three days' rest in the recumbent position brought about a complete recovery.

The point to which I would call especial attention is the absence of anasarca or œdema. At the time, this seemed difficult of explanation, and I consulted the text-books at hand. Harley* explains the existence of nephritis without dropsy, on the theory that only one kidney is involved. On reflection, this seems plausible enough; for physiology teaches that the kidneys act alternately. Bernard † has proved this alternate action in animals; and Erichsen, in a case of extroversion of the bladder, noted the same with regard to man. It is also well known that extirpation of one kidney from a living animal is not necessarily fatal. Physiologists have frequently performed the experiment, and no indication of disturbance of the eliminative functions has been observed. Pathology likewise furnishes abundant proof in sustenance of this theory. Many cases of pyonephrosis are recorded, wherein is total destruction of one kidney, and no œdema occurs. We have cancerous kidneys, with no accompanying œdema of the extremities.

On the other hand, we have theories advanced by prominent authors, to some of which I shall refer, as this is a subject peculiarly inviting to those fond of speculation. Loomis,‡ to whom I have already referred in discussing the etiology of dropsy, says: "Undoubtedly the most constant and perhaps the most efficient cause is the direct effect of the excess of urea upon the capillary circulation, and upon the composition of the blood." In the case under consideration, there were no evidences toxically of excess of urea in the circulation at any period of the disease, unless, perhaps, we except her condition on the morning of August 13th, when nausea and drowsiness were present; yet even then the vital signs were normal. *Urea* is claimed by Dr. George Johnson § to be a powerful diuretic, and to the excess of this in the system he attributes the copious flow of urine, which occurs during convalescence from acute Bright's disease. When injected into the veins of a dog, he further states, it quickly excites an abundant flow of urine. I should like to quote more at length from this author, but a lack of space forbids.

Another theory for the cause of dropsy is, that it is due to the sudden removal from the body of a large amount of albumen. If that were true, our patient should have been dropsical. Niemeyer † regards the dropsy in croupous nephritis as due to a suppression of urine, causing an increase of pressure upon the veins of the kidney. In my case there was no suppression, and this fact, taken together with the abundant hæmaturia, and the absence of any suppressed action of the skin, affords a plausible explanation for the lack of dropsy.

Johnson adduces a very good argument to prove that the suppressed action of the skin in the desquamative period acts as a concurring cause of dropsy in albuminuria. "Frerichs," so Steiner states, ‡ "has described a rare form of dropsy, without any disease of the kidneys, occurring after scarlet fever, which he believes to be due to paralysis of the cutaneous nerves by exposure to cold during desquamation." Steiner himself has observed a similar case. Louis Thomas, § in his chapter on Scarlatina, says: "It is evident that the dropsy is connected with some affection of the vaso-motor nerves, and not dependent alone upon changes in the kidneys and loss of albumen."

Now, as I have already intimated, my impression is, that where renal hemorrhage exists to such an extent, and so passively as existed in the case herein recorded, we can have no cause for dropsy, whether one or both kidneys be involved. I am not prepared to assert this dogmatically, but hope to investigate this point still further as opportunity shall offer. It is curious to note the percentage of dropsical patients as recorded by different observers.

In Vogel ‖ I learn that Haidenhain found eighty per cent. of his scarlet fever patients affected with dropsy; that Jas. Miller found twenty-seven per cent.; Wood, of Edinburgh, twelve and one-half per cent.; Frerichs, only four per cent. Those interested in statistics may consult a paper read by Dr. Bradford Thompson ¶ before the Medical Journal Association of New York, January 10, 1873. The chapter in Ziemssen will repay a careful perusal.

Throughout the journal literature of the day I have searched for analogous cases as diligently as the debilitating influences of a summer month would permit, and in this labor I have been very kindly assisted by Dr. E. F. Horst, a fellow interne. I succeeded in finding two cases on record, and shall refer to them as briefly as possible.

At the Clinical Society in London, Mr. Arthur Andrews presented a case for Dr. Gee,** with the following history: A healthy young man incurred a nephritis from exposure to cold. The urine was highly albuminous, and presented the other signs of the disease. On the forty-third day only a trace of albumen was present, and the man was considered relieved. On the forty-fourth day, however, an intercurrent scarlatina appeared, and the urine *immediately* became almost

black from blood, and was loaded with albumen. Both blood and albumen decreased until the fourteenth day, then increased again to the forty-second (eighty-fifth day of the nephritis). The points of interest in this case were:

1. Sudden and abundant hemorrhage at the invasion of the scarlatina.

2. Rapid diminution of the hæmaturia until the ninth day of the fever, when there was no albumen.

3. Recurrence of the albumen when the urine of uncomplicated scarlatina becomes albuminous for the first time and its continuance from this period.

Bramwell,* in an article on Scarlatinal Anasarca and its Treatment, reports the case of a schoolmaster whose school the disease had invaded. He felt a little unwell one day, and consulted the doctor, who found the face puffy, the urine albuminous, and from the attending circumstances had no difficulty in arriving at the true diagnosis. A few days later both lungs became congested; convulsions followed. Venesection was performed, and "great relief" is recorded. Three days subsequently a phlegmonous inflammation of the arm which was the seat of the venesection supervened, pus formed, and the constitutional disturbance ran high. The urine became exceedingly bloody for several days. The administration of ergot was followed by a cure. The two cases thus related present some points of similarity with the one which affords a text for this paper; yet neither can be looked upon as pure and uncomplicated scarlatinal nephritis. I am unable to learn from the reports whether the dropsy existed during the hæmaturia. That it did not exist to any great extent, I think I am justifiable in assuming from negative evidence. Niemeyer† records a case of parenchymatous nephritis, one year's standing, in a girl, wherein œdema was delayed until one week after a venesection, and infers from this that the hydræmia which, though extant in moderation, was so much aggravated by the blood-letting as to cause the dropsical symptoms to appear. In the second of the two cases above mentioned, it might likewise be inferred that the hæmaturia, coming on the third day after venesection, was a dropsy into the kidneys, or, what amounts to the same thing, transudation of blood and serum through the Malpighian capillaries into the tubules. Local œdema, we know, is a very common occurrence.

In my case I can find no complications, unless we consider the hip-joint disease a complication; and from the absence of any acute symptoms I am disposed to exclude this as totally irrelevant. It may be significant to observe that during the illness a spontaneous cure of the joint disease seems to have taken place. The rest in dorsal decubitus that length of time would most likely have effected a cure. If we reject this, the question of metastasis of disease presents for consideration. In the article in Ziemssen to which reference once or twice previously has been made, I find an interesting paragraph bearing directly on this point, and as it expresses *multum in parvo*, I shall take the liberty of quoting it in full:

"When scarlatina occurs in the course of other diseases which are then generally irregular, it frequently increases their severity; according to Rilliet, especially if the other affection implicate organs which are apt to be affected by the scarlatinal poison. Thus, for example, Löscher regards the existence of a previous tuberculosis of the lymphatic glands as a very bad sign in scarlet fever; the more severe and extensive this lesion is, the more violent is the course of the disease, the more frequent its complications (meningitis, hydrocephalus, pleuritis, dropsy), and the more unfavorable its termination. On the other hand, other diseases, which are indifferent to the scarlatinal poison, not only do not change the character of the scarlet fever or interfere with recovery, but they may even exercise a salutary influence. Barthez and Rilliet state that scarlet fever has a favorable influence on phthisis—an observation which is approved by Oeiters but rejected by Hebra. . . . . Prevot has seen scrofula in a child cured by the occurrence of scarlatina maligna with the formation of abscess. The child afterwards permanently regained vigorous health."

Now if morbus coxarius be a strumous disease, scarlatina should effect a cure. This case was cured during the scarlatinal attack, which goes to prove that morbus coxarius is one of those diseases on which scarlatina exercises a salutary influence; probably it is strumous. I could show, had I not already prolonged my paper, cases of hip-joint disease seriously aggravated by the intercurrence of scarlatina.

Why does excessive hæmaturia occur in connection with this form of Bright's disease? Biermer‡ says that in the severer cases with hæmaturia and albuminuria the substance of the kidneys is hyperæmic and softened, and as a consequence the seat of numerous capillary hemorrhages. Huegenin has demonstrated that in scarlatina hæmorrhagica a diphtheritic affection of the mucous membrane of the pelvis of the kidney may exist, giving rise to copious hemorrhage. Many cases prove fatal, though none, so far as I have learned, wherein the kidneys were the seat of the hemorrhage.

Lovegrove† reports a case of scarlatina in the person of his own son. On the fifteenth day, after a mild attack, with enlargement of the parotid gland and otorrhœa as complications, a bright red hemorrhage issued from the mouth and nostrils, a branch of the internal carotid in all probability having ruptured. He refers to one or two similar cases unpublished. Then we have hæmatoma scarlatinosum. This usually appears on the neck. Dr. Huber‡ reports an interesting case in a six-year-old boy.

The treatment, of course, depends on the gravity of the disease of which the hæmaturia is symptomatic. If, as is plausible, the blood thrown off with the urine prevents the occurrence of dropsy and at the same produces no alarming loss of strength, no special treatment is indicated. Proper mangement is the one thing needful. I have had no experience in the use of ergot in hæmaturia, and consequently cannot speak advisedly.

In conclusion, let me enumerate the points I have endeavored to bring out in this communication.

1. The persistence of the hæmaturia for a period of four weeks.

2. The absence of any marked constitutional disturbance other than an unusual degree of emaciation.

3. The absence throughout the attack of any general or local œdema.

4. The influence of the intercurring scarlatina on the morbus coxarius.

UNIFORMITY IN THE PRACTICE OF PHYSIC.

By E. SEGUIN, M.D.

The first want of the members of an International Medical Congress is to understand one another; but we have not yet arrived at this ideal of internationalism. The unity of language founded upon the mother-tongue of Europe has been broken when it became evident that the Latin, instead of serving to propagate ideas, was used by the Congregation of the Index to spy their eclosion (hatching) and to burn them by the hand of the hangman. Fra Paolo hid his discovery of the valves of the veins, and its consequences, in the library of Padua for fear of the inquisition; Luther had to translate the Bible to cause it to be read; and Descartes lived in voluntary exile, and published his treatise on *The Method*, in French, in order to speak freely. So that the diversity of the languages we write since this revolution is as likely and as necessary to insure everywhere the freedom of thought, as to favor the complete expansion of individual and national geniuses.

However, one cannot fail to see that this diversity opposes a large obstacle to the interchange of ideas, even of feelings—a something similar to a veil spread at the frontiers to arrest them, and which prevents the fecundation which takes place by the natural process of distant pollenization.

This defect was first felt by the naturalists and chemists, who, already at the end of the seventeenth century, tried to create nomenclatures, symbols, and measures, in view of their common acceptance by all the nations. This uniformity, as well as the other one previously created for the mathematical language by our masters, the Arabs, permit us to read, almost without linguistic preparation, the books of chemistry, of physics, and of mathematics written in almost any language.

We would like to be able to say the same thing in medicine; but daily experience has taught all of us how difficult it is to read foreign observations, and even to compare ours with those of our fellow-citizens and near neighbors.

This anarchy, which seems the arcbeus of our profession, caused incalculable retardment in medical advancement, and has been the principal theme of the protestations, whose series forms a chain of which the present memorial is but the last link.

1832.—Louis, Andral, Chaumel, founded the *Société Médicale d'Observation*, whose main object was to influence the medical mind, to elevate it to the comprehension of the importance of observing all the morbid phenomena with precision, to report all the cases with mathematical exactness, to propagate and develop the *numerical method of observation* of Louis. If such men had been supplied with the instruments of positive diagnosis recently invented, the results of their efforts would not have remained limited to a small circle of devoted disciples.

1860.—The celebrated chemist, Dumas, demanded, in the preface of the French Codex, the *unification* of the codex of all the parts of the globe.

1865.—At the first Pharmaceutic Congress meeting at Brunswick, the question of the uniformity of medical preparations and doses filled several sittings; Danckwortt made on it a favorable report, which was supported by Robinet and Guibours, and unanimously accepted.

1867.—At the second Pharmaceutic Congress of Paris, where were present the delegates from seventeen nations, the question of establishing everywhere the uniformity of officinal preparations was then commended: "To study the means of composing a codex, or legal formulary, which could be accepted as universal for the officinal preparations whose uniformity in all civilized countries is most desirable."

The learned Mialhe made, upon the proposition, a report whose perspicuity is characterized in the following extract: "At a time when the means of communication between people become so easy, we feel for all the men stricken by the same diseases, and suffering the same pains, the necessity of a uniformity of treatment, based upon the unity of pharmaceutic preparations in all civilized countries, so that a medical prescription could be identically executed in Paris, London, Vienna, Berlin, or in the United States, etc., with the same ease for the pharmaceutists and the same security for the patients."

Upon this report the Congress of 1867 decided, that: (1) A universal codex must be adopted. (2) It will be written in Latin. (3) The metric system will be used in it. (4) A special commission will be named *ad hoc*, and will begin immediately.

Not less important and more precise were the resolutions received from Spain before the closing of this Congress of Paris.

1867, *August* 21.—The College of Pharmacy of Madrid concluded a long discussion on the same subject, by the adoption of the following resolutions: (1) Realization of a universal pharmacopœia, which must be the result of the concourse of representatives of all the medical sciences, and keep in view the particular conditions of general health in the various countries. (2) The redaction of this universal pharmacopœia can be commenced immediately, with the assent and concourse of all the nations who feel an interest in its execution. (3) As soon as the principle will be admitted, it would be next in order to charge an international commission with the redaction of this code of pharmacy, and to cause the compound preparations to be reduced in their composition to their simplest elements.

1869.—The third International Pharmaceutic Congress met at Vienna, where the question of a universal codex came up again. The decisions of the former Congress were reaffirmed, and the Society of Pharmacy of Paris was intrusted with the work preparatory to the realization of the plan of a uniform pharmacopœia. The names of the commissaries testify of the importance attached to the work: Buignet, Lefort, Mialhe, Wurtz, Planchon, Junghfleisch, Roucher, Duquesnel, Guichard, Mayet, Méhu, Boudet, reporter. His report, delayed by the Franco-German war, was read.

1874, *July*—and the Society of Pharmacy of Paris voted that it would serve as the preface to the project of the international codex.

1874, *August*.—At the International Pharmaceutic Congress of St. Petersburg twelve nations were represented, Boudet presented his report, and Méhu deposited the project of universal codex, elaborated by the Pharmaceutic Society of Paris. After three sittings given to a thorough discussion of this instrument, was voted the unfortunate proposition of asking the Russian Government to ask from the other Powers the nomination of commissions of inquiry, which would have capacity for modifying or accepting the proffered plan. It was to play the precious value of time on an illusion. What we cannot do ourselves for ourselves, no government can do it for us. The same illusion begged the kings to cure scrofula till Eliza-

beth refused to do it. Two years were thus lost without reckoning the discouragement.

However, this check from outside gave the next reporter, Gille, the occasion to view the subject on a broader aspect. On one side, the question of uniformity of medicaments must be appreciated by the druggists and pharmaceutists in regard to the purity of the substances, and the reactions of the primary elements; but, on another side, the physicians and physiologists are the judges of the action of the chemical produces, and of the compound preparations from the pharmacy on the living organism. Therefore, Gille resolved to present his work to the next International Medical Congress, where he said—

1876, *September*—"The pharmaceutists have, so far, almost alone prepared the labors which will likely serve as the basis of an international codex. It would, however, be very useful to not engage ourselves much further in a work of this importance without the help of the experience of physicians; for, to deprive ourselves completely of it would expose to severe criticism, and assume a responsibility which physicians can bear better than us. I am, therefore, of the opinion that if an International Commission must be charged with the final redaction of a universal codex, we ought to admit in it some physicians, veterinary surgeons, etc." This was a great step in the right direction: but this reporter did not advance in it alone, as we shall see.

The question of uniformity in medicine had already been the object of individual studies and of collective resolutions in several medical societies. The American physicians had treated of it, and acted upon it several times during the last years:

1873.—Before the New York Medical Journal Association; before the American Medical Association assembled in St. Louis, Mo.; before the British Medical Association, meeting in London; at the Association Française pour l'Avancement des Sciences, Section of Medicine, meeting in Lyons.†

1874.—Before the American Medical Association, assembled at Detroit, Mich.;* at the British Medical Association, meeting at Norwich; at the Association Francaise pour l'Avancement des Sciences, meeting at Lille.

1874-75.—Intercurrently, the question of the uniformity of the means of medical practice and observation had been the object of several conferences in Paris, where the Professors Marey, Potain, Lépine, Ball, Brouardel, and Lorain, till his death, showed a great interest and the desire of coöperating in the plan of uniformity, whose *ensemble* and most of the details are entirely of American origin.

1875, *June*.—The American Medical Association, meeting at Louisville, Ky., after hearing the report ‡ and upon the proposition of its General Secretary, W. B. Atkinson, delegated Drs. Adrian and Harwood to the International Medical Congress of Brussels, commissioning them expressly to give the assent of the American profession to the introduction of the French metrical system in physic, and to ask the Congress to take the measures proper to insure uniformity in all that pertains to physic all over the civilized world.

1875, *September* 23.—The memorial of these reporters was read in French by Dr. Collignon. *During the previous day*, Meltanche Sor had opened the Section of Otology by the question, "On the means of measuring audition, and of registering its degrees by a uniform method in all countries." In the same Section, Sapolini demanded that uniform inquiries be made internationally on the causes and frequency of the surdi mutity, surdity without mutism, mutism without surdity, and stutterism. *The following day*, in the Section of Ophthalmology, Donders proposed to introduce the metrical measures, instead of the English, French, and Prussian inch, in the measurement of the glasses of spectacles. Javal supported the proposition, the more heartily, since Giraud-Teulon had already graduated his test-glasses accordingly on the metric scale, and Snellen had, too, accommodated his type-letters to the metrical numeration of visual defects.

So the question of the uniformity of instruments, scales, and doses in physics was treated in three Sections of the Congress of Brussels, supported by eminent professors, in its application to distinct specialties, to pharmacy, to otology, and to ophthalmology, and exposed in its generalities by delegates who had expressly come from the United States to urge the adoption by the Congress of this plan of uniformity of language and of action, without which the internationalization of physic will remain a chimera.

Who could believe, if it was not a fact with its dates, that these men of talent or eminence who had come from so far in Belgium to support the same principle—medical uniformity—in several of its special applications, did not try to see and to understand each other; and that, united by the bonds of a common idea, they remained isolated in the bounds of their specialty.

Therefore, these men spoke under the same roof, in adjacent chambers, without communicating with each other, or concerting their efforts; without suspecting that they were giving one of the finest examples of medical anarchy, the best demonstration *per absurdum* of the necessity of uniformizing and of coördinating all the parts of our art, and of internationalizing the whole.

In consequence, the propositions above quoted received the approbation of the members of the Congress, but the Congress, as a body, did not come to any practical conclusion.

1876, *June*.—The American Medical Association meeting in Philadelphia, having heard the reports of Harwood and E. Seguin (see Transactions, etc., 1876); considering that the theoretical success, and the practical postponement of the execution of the plan of proposed medical uniformity are, one, the proof of its excellence, the other, the demonstration of the force of mind-and-habit prejudices which the projects are meant to conquer, sent this time to you a special delegation composed of the first originator of the plan, and of its last reporter in Brussels. These were expressly charged with the duty of pleading the necessity of uniformity in the means of treatment, of observation and of language, before this assembly, which, at this very moment, must feel the want of such a uniformity, without which international communications remain, to say the least, incomplete.

1876, *September*.—Thus we are here prepared to sum up the idea of which we have just traced the history, as much to encourage those who are apprehensive of novelties, by showing what long roots this one has a ready shot in the muck of physic, as to point out, on the road of those who will follow, the difficulties previously encountered.

It remains now to say a few words of the general bearing of the subject. Of that which distinguishes the American plan of general uniformity from those successively presented in the interest, and for the advancement of special parts of our art; namely, from

* Transactions, etc., 1874.
† See *Compte rendue*, etc., page 828, et s.
‡ Transactions, etc., 1875, page 31.

those of Dumas, Mialhe, Gille, Boudey, Meltanche, Sapolini, Javal, Donders; the adoption of which would improve some parts, but not the whole art.

In contradistinction, the American plan—which is nothing else than the *Numerical Method of Observation*, introduced by Louis forty-four years ago, but rendered more precise and practical by the recent invention of new means and instruments of positive observation—is at once distinguishable by the broadness of its applications to physic; being at the same time a principle and a method. And as nobody can sum up the influence in physics and metaphysics of the Cartesian and Baconian methods, so, and more, would it be futile to pretend to calculate the influence which will obtain on the progress of physic, by a method of observation based on mathematical uniformity; but we can already foresee some of its consequences.

The uniform application of the numerical method will render infinitely more abundant, accessible, readable, comparable and trustworthy, the observations on which the leaders support their theories or discoveries, and by which the country-practitioner will connect his mind with the medical movement, and eventually act his part in it. It is so that the records of each will be of service to all. The practice of physic will gain in certainty in several ways. The diagnosis will become more and more precise and mathematical. The course of diseases will be more and more represented in figures, or idealized in graphic traces.

The action of medications on the organism, and the reaction of the functions on the treatment will be registered and reckoned as book-accounts.

Physicians are expected to no more write their prescriptions or borrowed slips of paper without keeping a copy, or on druggists' blank advertisements; neither to record their cases on pocket-books which contain the names of all the saints to be daily invoked to obtain a cure, instead of on books on which can be noted the physiological signs, or aberrations of function, which characterize diseases.

The uniformity of the tables of observation used in private and hospital practice, will furnish the sure elements of a medical statistics, not only in regard to the transitory population of hospitals, but to the families treated at home; it will present for the first time the true and full data for a history of health and disease.

From a different, if not a higher point of view, the mind of physicians will gradually relinquish the process of guessing and believing for the one of trusting their own senses and acting according to their own impressions and counsel. Thus the bulk of our knowledge will steadily be categorized in its natural divisions of savage traditions, barbaric panaceas, priestly impositions, rational systems built on hypothesis, physical and positive acquisitions of experience mathematically coördinated.

In presence of these well-defined series, who will not, with equal eagerness, scorn at the first ones, and try to add a line to the last. When all the physicians will be furnished with uniform means of mathematical certainty all will be enabled to contribute to the general labor; and who can say where our progress of certainty in physics will stop? Physics will be—without any more contest—one of the physical sciences. But let our first word be the last too; no international onward movement is possible without a mathematical uniformity of plan and of understanding.

Such is the sum of the plan of *uniformity in physic*. Will it be opposed on the plea that its vastness renders it impossible? But it is not only possible, it is commenced. Have we not the Reports of Boulet and Gille, the plan of a universal codex of Mehu, the adhesions of Donders, Javal and others in regard to their specialty; the proposition of Bouchardat to actually commence the *uniformization* of medicaments by the most energetic, which would be like a continuation of the labors of Magendie, in which are found his solution of morphine and other preparations of alkaloids which have become officinal, even international.

The uniformity of nomenclature of remedies and of diseases would follow, since there is no reason why they would not be called by the same name the world over.

A double uniformity in our instruments would follow: one mechanical, by which the parts being made of numbered calibres, could be changed without trouble and hardly any expense. The other, more professional, would consist in a uniformity of all graduated calibres, capacities and scales. To not penetrate too deeply in the future, you can at any time declare it obligatory for family practitioners to keep their private clinical notes like those of the hospitals, and devise a greater and gradual uniformity in the latter.

Thus the International Medical Congress can continue, with a view towards a general end, a work begun by individuals who had only in view the improvement of some special parts of our art.

In consequence of these considerations we reiterate before the International Medical Congress of 1876 the proposition enunciated in 1873, 1874, and 1875, under the patronage of the American Medical Association; and we formally ask you: (1) To recognize in principle the legitimacy and the necessity of uniformity in the practice, in the observations, in the records, and in the medical language of civilized nations. (2) To prepare a plan of uniform hygienic and sanitary measures applicable to the prevention or disappearance of contagious and epidemic diseases. (3) To constitute an International Council, charged with the elaboration of the means of establishing a uniformity of nomenclatures, of officinal formulas, of methods, of instruments, of scales, of mètres and tables of registration for pathological cases and physiological experimentations. (4) Also with power to call in men eminent in the sciences and arts accessory to physic, and the most capable of giving to the labors of the council the most simple and practical direction. (5) To head the list by the names of Boulcy, Donders and others already quoted, whose previous labors will have to be taken into serious consideration, and melted, if possible, in the general plan. (6) To give to the council, thus constituted and strengthened, the power and the duty to communicate its report to the next International Medical Congress, which shall meet at Geneva, Switzerland, in September, 1877.

Thus will be rendered possible the continuation of an *œuvre* whose foundation has already occupied thoughtful men during several years—a work which time will achieve, if we diligently labor at it; and which our children will have often to mend, in order to keep it up to the intellectual level of their epoch; since ideas grow, fall, and succeed each other like the leaves of trees. We will have planted the tree, and they will garner the best crops.

DANGER OF VAPOR BATHS.—An old man, aged seventy, recently died in a vapor bath in Paris from cerebral congestion.

Progress of Medical Science.

CILIATED PUS CELLS.—While examining the secretions from the mouth and pharynx of a frog, when irritated by a weak solution of osmic acid, Prof. Neumann, of Königsburg, found certain cells having characters intermediate between those of epithelium and ordinary pus cells—having, in fact, the cilia of the one and the contractility, the size, and the opaque nucleus of the other. The cilia covered but a part of their surface, and imparted to them a rotatory motion, the amœboid changes of form beginning only when the cilia ceased to move. Here are, then, all of Cohnheim's characteristics of pus-corpuscles, and an argument for the occurrence of true epithelial suppuration. Such bodies have, it is true, been seen before, but they have been regarded as ciliated epithelial cells of the part, mechanically detached.—*Centralbl. f. d. Med. Wiss.*, June 10, 1876.

OIL OF THE SMUT OF CORN IN THE TREATMENT OF ECZEMA AND CHLOASMA.—Prof. C. Lombroso reports a case of chloasma of the forehead and cheeks of a year's standing, which he treated on one side with red oil from the smut of corn and on the other with rancid oil from sound corn. The former proved much the more efficacious, removing the patches after three days' use, but the unpleasant effects on the system at large made the patient unwilling to resume its use. The same remedy effected the cure of a patch of eczema on the chin of an insane patient in five days.—*Centralbl. f. d. Med. Wiss.*, April 29, 1876.

ABLATION OF THE CUBOID BONE IN CONGENITAL VARUS.—Dr. H. J. Little says the only cases where this operation can be performed are those where inveterate deformity exists, and which are curable by no other means. Infantile congenital club-foot, he says, can, and ought to be, cured before the age of twelve or sixteen months, before the time a child commences to walk. If properly treated at that time, he thinks the use of splints and any mechanical aid will be unnecessary in walking.—*Brit. Med. Journal*, May 13, 1876.

OPERATION FOR OBLITERATION OF DEPRESSED CICATRICES AFTER GLANDULAR ABSCESS OR EXFOLIATION OF BONE.—Mr. William Adams has performed this operation with great success. So many faces are rendered unsightly by these deep cicatrices, that any operation which results in the removal of the deformities must be a blessing to those afflicted by them. The operation is original, and consists in subcutaneously dividing all the deep adhesions of the cicatrix, by a tenotomy-knife introduced a little beyond the margin of the cicatrix, and carried down to its base, so as to carefully and thoroughly evert the cicatrix which remains prominently raised. Two hare-lip pins or fine needles are then passed through the base, at right angles to each other, so as to maintain the cicatrix in its everted and raised position, where it is so retained for three days. At the end of this time the needles are removed, and the somewhat swollen and infiltrated cicatricial tissue is allowed to settle gradually down to the proper level of the skin. He gives the full history of three such operations in his paper. The permanency of the cure is illustrated by cuts of two cases, in one of which the operation was done nine, and in the other three years ago. The depressions seem to be completely obliterated.—*British Medical Journal*, April 29th, 1876.

DR. REYHER'S REPLY TO KRÖNLEIN.—Not content to leave the vindication of his statistics even in the friendly hands of Prof. Volkmann, Dr. Carl Reyher, of Dorpat, sustains his position regarding the antiseptic treatment of wounds, against what he regards as the misconceptions or misrepresentations of Dr. Krönlein, in a detailed article in No. 4, vol. xix., of *Langenbeck's Archiv*.

EXTIRPATION OF A LARGE MYOMA OF THE BLADDER.—Richard Volkmann reports the removal by him from the bladder of a man of fifty-four, of a myoma the size of a lemon, which was attached by a short pedicle to the summit of the bladder. The symptoms, which had existed for about six months, consisted in difficulty in urinating, in the passage of large quantities of blood, and in the occasional discharge, per urethram, of masses of a fibrous consistency. The diagnosis of the tumor was made by the employment of bimanual palpation, with two fingers in the rectum. The operation, which was performed on Nov. 30, 1874, was preceded by an exploratory perineal section, by which the exact location of the growth was determined. This was immediately followed up by the supra-pubic section of the bladder, through which the polypus was removed. The patient died in collapse on Dec. 3d, as a result of peritonitis and suppuration of the connective tissue about the bladder. Volkmann refers to an analogous case of Billroth's, a notice of which will be found in the MEDICAL RECORD of July 3, 1875.—*Archiv f. klin. Chirurg.* xix. 4.

ON THE SPREAD OF CANCER IN THE LYMPHATIC GLANDS.—DR. BOZZOLO, of Turin, announces the following views as the result of his own observations on the extension of cancer to the lymphatic glands, viz. that the cancer cells first appear in the lymphatic glands in the cavities of the cortical substance; that they are often, even in the beginning, well developed, and many of them have already become horny; and that the endothelial cells of the sinuses and the connective-tissue cells covering the trabeculæ of the reticulum, furnish no traces of cancerous proliferation. Hence he concludes that the cancerous elements are brought to the glands by the afferent lymphatics, quite independently of any proliferation of their connective tissue cells. By the constant accumulation of the cancerous elements in the lymph canals, he says, these become enormously distended, lose their contour, and in advanced stages render it impossible to recognize the structure of the lymphatic gland.—*Centralbl. f. d. Med. Wiss.*, May 6, 1876.

THE COURSE OF CERTAIN BRAIN FIBRES.—A. FREY communicates the following case to the *Arch. f. Psych. etc.*, vi. p. 327. A man died of erysipelas soon after the development of the symptoms of a localized cerebral paresis. At the autopsy the only lesion found was a small, sharply circumscribed focus of softening in the middle of the white substance of the right hemisphere, at the level of the under surface of the corpus callosum, between the nucleus caudatus internally and the fossa of Sylvius externally, at about the height of the anterior third of the corpus striatum. As the paresis involved the whole left arm, left angle of the mouth, and left half of the tongue, it was assumed that the fibres for the innervation of these parts must run through the seat of softening.—*Centralbl. f. d. Med. Wiss.*, May 6, 1876.

STATISTICS OF RESECTIONS OF THE ELBOW-JOINT FOR GUNSHOT WOUNDS.—The following conclusions are taken from Dominik's article in the *Deutsche Militairarztl Ztschr.* No. 1, 1876. The elbow-joint is

the one most frequently involved in gunshot wounds, and the right more often than the left. The expectant conservative treatment of these injuries in the Franco-German war of 1870–1 gave better results as to mortality than in former wars, because it was employed only in the lighter cases. It almost always results in anchylosis of the joint. Resection of the elbow as compared with amputation of the upper arm for gunshot wounds gives a mortality of 23.8 per cent. against 35 per cent. for the latter. In the late war, primary resections, *i.e.*, on the 1st and 2d days, did not give as good results as secondary. Partial resections, when possible, are to be preferred to total. The results of resections of the elbow in the late war have been as follows: with regard to function, 51 per cent. more or less favorable; 49 per cent. anchylosed, and of the whole number only 24.4 per cent. dangling arms. Among the latter, primary resections furnished the largest numbers. The best functional results are from secondary total resections, the worst from primary. A deterioration of the effects of resection in the progress of years, has not been observed since the late war; on the contrary, an increase of usefulness of the resected joints has taken place. Amputations of the upper arm after previous resection of the elbow-joint gave nearly twice the percentage of mortality of amputations of the upper arm in the last war. The mortality of amputations of the upper arm after wounds not involving the elbow-joint was a little less than the average mortality after resections of the elbow-joint.—*Allg. Med. Cent. Zeit.* May 10, 1876.

The Treatment of Santonin Poisoning.—At the session of the *Niederrheinische Gesellschaft* in Bonn, July 5, 1875, Prof. Binz mentions a case of poisoning by santonin, in which a child of two years had taken 1½ gr. of the drug. There were violent convulsions, beginning in the face and extending to the extremities, and great interference with the breathing. She recovered under the use of warm baths, vinegar enemata, plenty of fluids to drink, and artificial respiration. Prof. B. then instituted some experiments on animals to elucidate the treatment, and found that chloral in doses sufficient to produce deep sleep prevented the convulsions, and that ether inhalations exercised a controlling influence over them. He thinks the same treatment may be employed in the human subject, coupled with artificial respiration, and, for purposes of elimination, laxatives and diluents in abundance.—*Rundschau*, May, 1876.

Dyspeptic Asthma.—At a late meeting of the Berlin Medical Society, Prof. Hennoch detailed the histories of several cases of this affection occurring among children, which had come under his observation. The symptoms were alarming dyspnœa, with pallor of the face and lividity of the lips, coldness of the extremities, small and extremely frequent pulse, superficial and very frequent respiration, and great mental apathy. The affection apparently depended upon disturbance of the digestive functions. There were in all of the cases some tumidity and tenderness in the epigastrium; but in spite of the threatening symptoms, not the least indication of cardiac or pulmonary disease could be found on repeated and careful examinations. In one case, that of a child of nine months old, in whom there had been constipation and vomiting, great relief was afforded by the application of numerous dry cups to the chest, and recovery from the attack coincided with the eruption of an incisor tooth. The other patients were children of nine years, three months, and two years respectively, and all were relieved by the action of an emetic or cathartic. Prof. H., although sceptical at first, ultimately came to agree with the opinion expressed by Traube, who saw the first case in consultation; viz., that the disturbance in the stomach excited a reflex vaso-motor spasm in the small arteries, whence followed the coldness of the extremities, imperceptible pulse, stasis in the venous system and right heart, cyanosis, accumulation of carbonic acid in the blood, and dyspnœa. He therefore assigns the name *asthma dyspepticum* to the affection.—*Berl. klin. Woch.* May 1, 1876.

Chronic Purulent Peritonitis cured by Aspiration.—A woman who had been confined in the month of May, 1873, and subsequently suffered from a diffuse puerperal peritonitis, entered the Hôpital Cochin in October of that year. The abdomen was found symmetrically swollen, and everywhere dull on percussion. Aspiration was performed seven times within a period of two months and a half, and seven and a half quarts of pus were withdrawn. The punctures had to be made at different points, because the pus was contained in pockets; after each operation compression was applied to the abdomen. This peritonitis had developed with very little fever and pain, and the general health had continued pretty good.—*Lyon Médical*, June, 1876.

Treatment of Hydrorachis by the Elastic Ligature.—M. Mouchet reported at a recent meeting of the *Société de Chirurgie*, two cases of hydrorachis, in one of which, the tumor, which was situated over the sacrum, was punctured on the day of birth, and an elastic ligature applied to its base. As, however, the ligature became displaced, the section was completed by the knife and sutures were applied. The wound united after some delay, and the cure was complete on the 21st day. In the second case, the tumor was four inches long, by two and a half broad, and was situated in the lumbar region; a ligature was applied without previous puncture, but the child died eight days later from causes that had no connection with the operation. The same operation has been performed six times by other surgeons, and was successful in three cases. In two of these cases, the lesion was situated in the neck, which is a favorable position for it, for the tumor then rarely contains nervous elements. In tumors of the base of the vertebral column, the method of Morton, which consists in injections of fifteen minims to a drachm of the glycerine of iodine, according to the size of the tumor, would be preferable.

In the discussion that followed, several members of the society protested against the operation. M. Blot said that these tumors often disappear spontaneously, and that consequently we should not interfere, except when the walls of the sac are too thin. M. Polaillon thought that the operation should only be undertaken when the tumor is increasing and becoming a deformity. M. Larrey said that he had seen a man, 27 years of age, who had a hydrorachis of the lumbar region, which caused him no inconvenience. M. Guéniot called attention to the fact, that the canal of communication between the tumor and the cord has cartilaginous walls, and may be obliterated in the process of development of the skeleton. M. Depaul opposed the operation, because the tumor almost always contains nervous elements. As regards the cures that have been obtained, there is cause to believe that tumors of the vertebral column have been mistaken for true spina bifida, which is a tumor which comprises the envelopes of the cord.—*Journal de Méd. et de Chir.* June, 1876.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, August 26, 1876.

THE INTERNATIONAL MEDICAL CONGRESS.

As the time approaches for the meeting of the International Congress at Philadelphia, the anxiety concerning its success increases. We have no doubt that the gathering will be large, and that the different leading medical societies of the world will be well represented. From all the larger cities of Europe assurances have come signifying the acceptance of invitations, and responsible delegates have been elected. It is fair to presume that the great majority of the foreigners who have already signified their intention to read papers and deliver addresses will be able to keep their appointments, and that the scientific material for discussion will be abundant. In prospecting the interest which will attach itself to this Congress, the profession of this country should recognize the arduous labors of the Committee of Arrangements at Philadelphia in perfecting a plan, which, as far as circumstances would admit, is so well calculated to subserve the interests of all the different medical centres of this and of other countries. In fact, the more we study the programme of arrangements the more are we impressed with the wisdom exercised in the selection of subjects and the judgment displayed in the choice of the speakers.

The time selected for the meeting, all other things being considered, is the one best calculated to meet the conveniences of the larger majority, especially of those who will cross the ocean to be present. The occasion of the meeting, and the special attractions of the Centennial show, will add inducements which few of our foreign brethren, who wish to combine social amusement with professional profit, will care to resist.

The delegates from the different leading societies of this country have been without exception selected with great care, and altogether the coming Congress is destined to be the largest and most influential of its sort that has ever assembled.

It is impossible to predict the mutual influences for good which will be exerted upon native and foreign delegates. Such influences will be more or less powerful in proportion to the existence of an understanding to work individually and collectively for the common good of medicine and the general advancement of scientific knowledge. It will be our aim to prove to our distinguished visitors that we, as a profession, are keenly alive to the necessities of the medical science of the nineteenth century, and that while we in many cases look to them as our teachers, we are not behindhand in original research, and in that love for advancement and the attendant substantial progress which it attains. While we are willing to respect the influences of their labors in the cause of science, we ask, and shall doubtless receive of them, a substantial recognition of services in the same direction.

The assembling, however, of such a large body of influential medical men must have a significance which is independent of these considerations. It should not be viewed as a mere medical society for the discussion of cases and the particular methods of treating diseases, but as a world's Congress brought together for the discussion of general principles in medicine, general laws of disease, general methods of observation and study, and the general influences of climate, altitude, etc. The opportunities for the presentation of views upon these subjects, in view of the wide-spread representation at the Congress, should not be lost to science. We shall probably have men from every part of the globe, who are able and willing to speak on all these subjects in connection with the professional sentiments of their respective countries; men who can contribute to a general fund of experience, which may serve as the starting-points for new and more exact methods of study and of observation. The higher we get in the study of the general principles of our art, the better will we be able to take a more extended review of our resources, and the more effectually can we look over the prejudices of hobbies, of doctrinal perplexities, and of party interests.

The first step in the direction of studying disease after this general plan is to establish some methods of observation which shall be uniform throughout the world, some mathematical language which shall be universally understood. The presentation of this particular idea is not new to the readers of the RECORD, and will remind them of previous efforts on our part to point out its necessity as the real starting-point of medicine as an exact science. What better time and place will be afforded than at the next Medical Congress to agree upon some general plan of action, to make some earnest beginning in the right direction? The way is already prepared by the appointment of a committee whose duty it is to bring the matter before the meeting. One of the members of this committee

is Dr. E. Seguin, of this city, whose special study of this subject entitles his views to respectful consideration. It will hardly avail the Congress to discuss the propositions in all their bearings, as this will consume too much valuable time. All that is expected for the present is the establishment of the principle, and an agreement upon a system which shall make its universal application practicable. The time and opportunity are auspicious, and there is no good reason why the initiative should not be taken at once. The idea is essentially an American one, and should receive its practical endorsement during the Congress held in this country. The necessity for such a system of uniformity of observation can hardly be questioned; in fact it has been practically recognized by the specialists, and its adoption has tended more than anything else to give positiveness to their experience and substantial progress in their departments. All that is necessary is to extend the influences of such a system so that it may have an application to the whole domain of general medicine. Of course it may require years before any plan which may be suggested is universally adopted, but this is the most powerful argument in favor of making a beginning at once. In giving our idea of the scope of the discussions which should be had before an International Medical Congress, we have no intention of reflecting upon any arrangements of the committee who are to conduct the meeting. In fact, the character of their programme is not inconsistent with a very liberal interpretation of our sentiments; and if circumstances will permit of their carrying out the letter and spirit of their plan, the meeting cannot fail to be a brilliant success.

Reviews and Notices of Books.

THE TREATMENT OF SYPHILIS. By J. L. MILTON, Senior Surgeon to the St. John's Hospital for Diseases of the Skin, London. London: R. Hardwicke, 1876.

MR. MILTON has long been recognized as an authority of high standing upon cutaneous and venereal diseases; and works from his pen have been received with much attention, owing to their eminently practical character. This peculiarity, noticeable in all his former works, is especially so in the one under consideration, in which the author gives us, in a handy-volume form, the results of his long study and observation in the treatment of syphilis. Coming from an observer of the undoubted ability of Mr. Milton, the present treatise, which includes the full consideration of the treatment of syphilis, is especially acceptable; as we can be assured of its trustworthy and practical character. It is perhaps known that, within a year or so, Mr. M. published an article remarkable for the lucidity of its directions upon the treatment of secondary syphilis, which attracted considerable attention, as it was in reality a contribution from which much benefit as to practice could be derived. In the work before us, the author discusses, not only the secondary stage of syphilis, but also every possible lesion produced by that disease which the practitioner is liable to meet. From the primary sore to the latest tertiary manifestation, we find every syphilitic affection mentioned with sufficient but short clinical description followed by directions for treatment, which differ in their simplicity and appropriateness from those generally met, which, we are sorry to say, are often of no benefit, as they are not laid down with that precision necessary to therapeutic description. Indeed, amid the mass of literature upon the subject of syphilis, we do not know of so peculiarly practical and acceptable a work as the present one. In no text-book or monograph can the practitioner find the clear systematic handling of the subject of the treatment of syphilis in general as he can here. Within a reasonably small compass, the book consisting of but one hundred and fifty pages, we find the morbid conditions of the disease fully discussed, and the indications for cure admirably laid down. It seems strange to one after reading the work, that such had not appeared before, as its want has long been manifest. The author shows an extensive acquaintance, both clinical and practical, with the protean forms of syphilis; and his disquisitions as to the value of remedies, and to the appropriateness of certain operative procedures, as well as modes of treatment, can be read with interest by the specialist, and with great profit to the general practitioner. It certainly is a matter for congratulation that the author should have found time to give us the benefit, in so admirable a treatise, of the experience he has gained in his *pratique de cabinet*.

Correspondence.

AUTOPLASTY BY GRADUAL APPROACHES,

AS APPLIED TO THE SUCCESSFUL TREATMENT OF URINARY FISTULÆ IN WOMAN, IN THE CLASS OF CASES USUALLY THOUGHT TO BE AMENABLE ONLY TO PARTIAL OR COMPLETE OBLITERATION OF THE VAGINA; BEING A LETTER ADDRESSED TO DR. PAUL BERGER, AGRÉGÉ TO THE FACULTY OF MEDICINE OF PARIS, BY NATHAN BOZEMAN, M.D.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—In the month of November last, Prof Dolbeau submitted to me for treatment at the Hospital Beaujon, three women with four urinary fistulæ, which he said were incurable by the methods ordinarily employed in France.

Case I. presented a somewhat elliptical opening extending from the middle of the urethra to the cervix uteri, measuring longitudinally about five centimetres, and transversely between two and three. Broad cicatricial bands extended across the rectal wall, which effectually prevented movement of the uterus downwards. This case I did not treat.

Case II. had a small transverse urethro-vaginal fistula near the bladder, and at the same height a cicatricial contraction of the entire calibre of the vagina, to the extent of allowing only the point of the index finger to pass. This cicatrix involved both edges of the fistula, was thick and unyielding, thus rendering operative procedure upon the latter impossible. Here by preparatory treatment I secured access to the fistula in less than five weeks, and returned the patient to Prof. Dolbeau for completion of the cure, which he then thought could be effected without difficulty.

Case III. exhibited an urethro-vaginal and an urethro-vesico-vaginal fistula with a narrow bridge of in-

odular tissue intervening, and with almost complete atresia of the entire vaginal tract. In this case I converted both fistulæ into one and dilated the vagina to the extent of four inches in depth and 2½ in width. The fistula then presented an oval form, having its anterior border notched at the urethra, and, to the right of this point, firmly adhered to the pubic bone; it measured transversely 4½ centimetres, and longitudinally about 3¼. Now Prof. Dolbeau, not wishing to undertake the coaptation of the edges of the fistula, requested me to make the operation, which I did on the 17th of March. Firm union was effected at the first trial, excepting only two small points separated by the urethra. The left opening, the size of a No. 6 catheter, was caused by the cutting of the corresponding suture; and the right, the size of an ordinary probe, stood directly in the line of union. Both of these small remaining fistulæ can now be easily united, and the whole closed at a second operation, which Prof. Dolbeau will perform soon.

The principles of treatment employed in the third case has been commented upon at length and in a manner highly appreciative (*La France Médicale*, May 13 and 17) by Dr. Paul Berger, *agrégé* Professor to the Faculty of Medicine of Paris; and to this publication I would respectfully refer all who may feel an interest in the subject. But I may add here that Dr. Berger, in his remarks, has inadvertently made two or three erroneous statements regarding certain important points of practice, which in justice to myself need to be corrected.

For this purpose, and in order to define my position with regard to obliteration of the vagina, as a means of treating vesico-vaginal fistula, I now ask the use of your columns. This I deem essential for a better understanding of the subject, not only as regards the result attained in the case in question, but as a principle of general applicability to the cure of a not inconsiderable class of cases, usually regarded amenable only to tentative expedients.

A fistula, whether small or large, complicated with atresia in any form, is, to use a military expression, the stronghold, to be reached only in two ways, namely by direct attack and by gradual approaches. The first mode, scarcely need I say, was the one adopted by Jobert (de Lamballe), who made various superficial and deep incisions, principally upon the anterior wall of the vagina, for the purpose of freeing the borders of the fistula and gliding the tissues, his object *primarily* being to close the fistula. The procedure he called *Autoplastie par glissement*, and the plan, excepting the detachment of the bladder from the cervix uteri and from the pubic arch, has formed ever since a prominent feature in the practice of almost all surgeons. The second mode I adopted: *first*, for the purpose of freeing the edges of the fistula by incisions upon one or both walls of the vagina, and restoring the organ as near as possible with dilatators to its normal dimensions; and, *secondly*, as a measure of closing the fistula by coaptation of its edges. Now, to continue the analogy in regard to these preparatory and ulterior operations, and for the want of a better designation, I beg leave to call my procedure *Autoplasty by gradual approaches*, a term which seems specially appropriate, since it is readily descriptive of it.

A method which approached nearest in principle to the last-named, was that of Desault; namely, the employment of the tampon. But when it is recollected that Desault only recommended the tampon in cases uncomplicated with atresia, and simply as an obturator of the fistula, analogy of his procedure to it ceases. This procedure, in contradistinction to the other two, may be designated as one of *circumvallation*; and while it did favor the contraction of the largest-sized fistulæ, it was quite insufficient to complete the closure even of the smallest, save in exceptional cases, when associated with the important auxiliary of cauterization.

As to how I was first led, in 1854, to make the combination of repeated incisions and intra-vaginal dilatation with closure of the fistula, it is not necessary to refer in this connection. Suffice it to say that the plan was modified and extended from time to time, and did not reach its highest perfection until 1867. At that time I completed my bivalve self-retaining speculum, founded upon the principle of the parallelogram of forces, which enabled me apply a powerful and regulated force to the whole length of the contracted vaginal walls, and at every stage of the dilatation to discover and surmount even the smallest points of resistance; a thing I had not previously been able to do with the so-called duck-bill speculum in a certain class of cases, where obliteration of the vagina seemed to be the only alternative. To such a category, for example, belonged the third case at the Hospital Beaujon.

The invention about the same time of my *knee-chest support*, which secured the steadiness of the patient, and rendered anæsthesia safe in the anterior position, also contributed no little to the completion of the procedure as a whole.

As to the details of the procedure by gradual approaches, it is unnecessary to go over them here. This point has already been made sufficiently clear for all practical purposes by the able reports of Dr. Berger, and of Dr. Bandl of Vienna (*Wiener Medizinische Wochenschrift*, Dec. 4–11 18 25, 1875).

I will take the liberty in this connection to say, that the manner in which these gentlemen have presented the subject is in very striking contrast with the criticisms in the last-named Journal of January 15th, upon my operations in the General Hospital at Vienna, illustrating the utility of this new principle of treatment. Here the writer seems to have no higher view of the matter than the hackneyed one of sutures, and to entertain the opinion that a woman with a fistula, treated by having *her vagina shut up*, is as well off as another cured by *obliteration of her fistula*.

In Germany and Austria, scarcely need I say, *kolpokleisis*, or obliteration of the vagina in some part of its course, is a very favorite procedure with a large majority, if not all of the leading surgeons, a fact which may account to some extent for the unjust criticisms of the writer referred to.

To give some idea of the extent to which this operation is carried in those countries, I will remark that, during my sojourn there of twelve months, I saw sixteen cases of fistula, principally of the varieties vesico-vaginal and urethro-vesico-vaginal. Out of this number *five* were actually subjected to the operation for obliteration in the urethral portion of the vagina, with the following results: *Two* died on the sixth day after the operation, from phlegmonous inflammation and other complications; *one*, in which a small opening remained, became pregnant subsequently, and at full term ruptured the perinæum and the recto-vaginal wall, and was left with such an increase of the original difficulty as was thought to be beyond the reach of any operative procedure; the *fourth*, a young woman, completely unsexed, was threatened by her husband with abandonment unless she had the obstacle to his marital rights removed; the *fifth*, who had already undergone four or five operations, remained with the vagina at the seat of closure sufficiently patulous to permit the passage of the index finger into the

cul-de-sac above, and into the fistulous opening of about the same size; while *four* others, presenting various complications, were thought to be incurable by any other procedure—making in all nine, 56¾ per cent., with a mortality of two, 12½ per cent.

In justice, however, to Prof. Simon, the inventor of this well-known expedient, it is proper to remark that he resorts to it much less frequently than his numerous followers; who, having less experience and skill than their master, resort to it, where he would consider it unnecessary—a fact of which I became thoroughly convinced from my own personal observations.

Dr. Berger, in his remarks, justly says my procedure is one of *Anaplastie*, and may be divided into two stages. He then enumerates what he conceives to be the advantages and the dangers of it in practice.

First, as to the advantages. I am pleased to say he has rendered these duly prominent, in regard to the restoration of the calibre of the vagina, the freeing of one or both edges of the fistula, and the paring of the latter almost perpendicularly, at the expense of the entire thickness of the vesico-vaginal septum, in contra-distinction to the *broad vaginal denudations* usually described by authors, as a distinguishing feature of the so-called "American method." This last point of practice is not properly appreciated by many operators, and hence the failures which they often meet with, especially in the class of fistulæ with thin borders and surrounding inodular tissue. To these advantages he might have added that recto-vaginal fistulæ are equally amenable to the same plan of treatment, even when they are situated in the posterior cul de-sac, and the way is intercepted by thick and resisting cicatrices—a matter of no little importance, when a vesico-vaginal fistula coexists, and the question of obliteration of the vagina is presented. But the great and overshadowing advantage is the avoidance of obliteration of the vagina, which Dr. Berger has sufficiently indicated, though not strictly in accordance with the range of my experience. Here he does me slight injustice in stating that I believe every case of fistula can be cured by the system of gradual approaches. What I do believe and claim is that, in 90 per cent. of all cases, the fistula can be obliterated and the normal menstrual and sexual functions be preserved; and that of the five per cent. in which this cannot be effected, and obliteration of the vagina seems to be called for, little or no permanent good can result to the sufferer from the latter expedient, however successfully accomplished.

In the latter class of cases, according to my observations, the vagina is reduced to a mass of inodular tissue, somewhat resembling cartilage, complicated with partial or complete destruction of the urethra, or with recto-vaginal fistula, or with laceration of the perineum and the recto-vaginal wall—a condition of the parts rendering continence of the urine only possible in a few cases, and clearly impossible in all the others, to say nothing of the dangers attending the operation itself. I, therefore, insist that it is better in all such cases to leave the outlet of the vagina free for the unobstructed flow of the secretions, and to trust alone to a well-adjusted tampon or compress for the comfort and protection of the patient.

This leaves five per cent. for deaths, a maximum of mortality which, in my experience, I am happy to say, has not yet been reached.

Next with regard to the disadvantages or dangers of *Autoplasty by gradual approaches*. Of these Dr. Berger mentions rupture of the peritoneum, rupture of the bowel, and phlegmonous inflammation. Now I think I am justified in saying that Dr. B. has invested all these accidents with an undue importance, both in his review of Dr. Bandl's memoir (*Revue des Sciences Médicales*, April 15, 1876), and in his remarks now under consideration, as will appear by reference to the following facts bearing upon these points.

The word *rupture* conveys to my mind the idea of unwarranted violence; and consequently is to be regarded as a somewhat unavoidable accident, liable to occur in any and all cases without the greatest care; whereas the reverse of this is true, excepting care and prudence, which of course are to be observed by the surgeon under all circumstances. Of the case referred to in the Hospital at Vienna in which a small opening in the peritoneal cavity was made, the accident was unexpected, it is true; but fortunately it terminated without serious consequences; and the patient was cured, with unimpaired menstrual and sexual functions, a result thought by competent surgeons to be quite out of reach by the ordinary resources. Here there was a cicatricial band, which stretched across the vagina just under the posterior lip of the cervix uteri, which prevented the necessary depression of the uterus for closure of the fistula. The latter was principally situated to the right of the median line, and had its anterior border fixed to the posterior surface of the pubic bone—a condition of the parts very rarely seen, and just such as is supposed to furnish the indications for oblique obliteration of the vagina. This band, after having been put upon a slight stretch with my speculum, was carefully incised to the left of the median line. It showed no signs of yielding under the knife and pressure of the finger, until complete division had been effected, when it gave way, and with it the subjacent peritoneal covering. I had often before made divisions of cicatrices in the same locality and seen them yield by the same practice, and there was no obvious reason why such a result would not follow without accident in this instance. A single accident, however, of this kind in an experience of nearly a quarter of a century cannot, I think, be regarded in a very serious light, especially when the character of the fistula, the principle of the operation, and the final result are considered.

But this experience is not without value. In future I shall content myself in such cases with making two or three superficial incisions across the resisting band, and then trusting to dilatation. By pursuing this course, only a little more time will be required to accomplish the same end.

As to rupture of the bowel, I can only say that I have not yet encountered such an accident. In one instance, I purposely opened the rectum in order to reach the required dilatation of the vagina, and to place healthy tissue between the two ends of the divided cicatrix, with the ulterior object of relieving the neck of the bladder, also encircled by a cicatricial band, and the seat of an urethro-vesico-vaginal fistula. Both fistulæ in this case were closed, each at one operation, and a most excellent result secured.

I may say there is a certain form of vaginal atresia resulting from other causes than those of parturition, in which the above practice is not only justifiable but preferable, in order to save time and secure the best results. An illustrative case of this character I saw in the Hospital at Vienna, in the service of Prof. Carl von Braun.

Phlegmonous inflammation, Dr. Berger says, is to be apprehended from incisions and lacerations of inodular tissue. His reasons for this belief are entirely apropos, and would seem to have some foundation in fact, but my clinical experience does not justify such a conclusion. When it is recollected that, in the treatment by gradual approaches, a free outlet for the vesi-

cal, vaginal and uterine secretions is maintained, and that the greatest possible cleanliness is observed, the truth of my assertion will be obvious. With these precautions and the daily application of a solution of nitrate of silver to the exposed vaginal wounds, coupled with judicious pressure of the dilator, the dreaded danger referred to ceases in a great measure to be a factor in the relationship of cause and effect. It is this, I conceive, that places the principle of *autoplasty by gradual approaches* in so favorable a contrast with that of obliteration of the vagina, or kolpokleisis. In the latter procedure, the extensive denudations required upon the two vaginal walls, perhaps already in a somewhat morbid condition, are more or less exposed, in and above the seat of operation, to the poisonous action of decomposed blood, pus, and urine, which can only find an outlet through the narrow urethra—a condition of things eminently conducive, it must be admitted, not only to phlegmonous inflammation, but to pyæmia.

In support of what is above stated, in contravention to the alleged dangers of my procedure, I may say that I have, out of more than one hundred of all classes of cases, lost but three—one in 1858, in the Royal Infirmary at Edinburgh, and two in 1861, in my private hospital in New Orleans. The *first* was a woman with complete incarceration of the cervix uteri in the bladder, and in a bad state of health superinduced by alcoholism and other effects of irregular and vicious habits. In this case the object of the operation was to restore the os uteri to its position in the vagina, and at the same time obliterate the fistula. Both of these ends were obtained most satisfactorily; but unfortunately, phlegmonous inflammation supervened, which terminated in pyæmia and death on the sixth day. The *second* case, having a small uncomplicated vesico-vaginal fistula, died on the fifth day of the operation, it is believed from septicæmia, induced by infection of the hospital from a case of erysipelas. Two other cases in the same ward which had been operated upon, one for laceration of the perinæum six days before, and the other for hypertrophy of the cervix uteri two weeks, died almost on the same day, having identical symptoms, thus showing that death in the case of fistula was due to a cause other than that of the operation. In the *third* case, the patient whose health was somewhat impaired, and who had a small fistula complicated with partial atresia, died on the fourth day after lateral incisions were made. Here, from the smallness of the incisions, the comparatively little inflammation which followed, and the similarity of some of the symptoms to those of the above cases, there is reason to believe that the poisoned condition of the hospital played a most important part in producing the fatal result, although several months had intervened, and every precaution had been taken as to cleanliness and disinfection.

Now, as to the closure of the fistula and the best means of doing it. These points, although totally disregarded in the first stage of *autoplasty by gradual approaches*, are nevertheless of paramount importance as regards the final result; and cannot be passed over, as is too often the case, by the mere assertion that one method is as good as another. They acquire, I conceive, additional interest at this juncture, from the fact that many surgeons in France, Belgium, and Italy have faltered in their support of the suture, including the much-vaunted American method; and now strongly advocate, even in simple and uncomplicated cases of fistula, a return to the old methods of cauterization, and of hooks or claws, as employed by Naegele, Lallemand, Laugier and others, designating the latter as the *méthode par réparation immédiate secondaire*.

Professor Amabile, of the Royal University of Naples, has had the kindness to send me a most interesting brochure upon this subject (*Discours prononcé au congrès des sciences médicales de Bruxelles*, 23 Sept., 1875). With regard to the suture, he says: "The treatment of vesico-vaginal fistula by means of paring and suture, notwithstanding it has given splendid results and been earnestly extolled in our day, has never popularized itself among surgeons, and rests at present in the hands of only a few operators. Often in a country only one or two surgeons employ it. Distinguished operators, wishing to try it, have often given it up after their first failure. Again, patients, when fully impressed with the gravity of their disease, often cannot make up their minds to submit to a repetition of this mode of treatment, because it is, if not very painful and dangerous, always laborious, long and tedious for everybody—the surgeon and assistants even more than the patients themselves."

Now, with the acknowledged superiority of the suture to the above old methods, even by the class of surgeons in the countries named, it is easy to see why this lukewarmness in its support has sprung up. It can be referred to no other cause, as I believe, than want of success; resulting in a great measure, *first*, from inattention to the morbid conditions of the vagina, other than that of the fistula itself; *secondly*, from the employment of too broad or flat surfaces in the paring of the edges of the fistula; and *thirdly*, from the adoption of the dorsal or lateral position of the patient.

The three forms of suture best adapted to the closure of the fistula are unquestionably the simple wire interrupted, the double silk interrupted, and the button wire interrupted, which I name in the order of their first adoption. The first and the second forms are now most generally employed by surgeons, under the belief that they are more simple, and quite as efficient as the last mentioned.

Now, without stopping to discuss the subject, I will simply say, that while the above convictions may be correct as to uncomplicated cases of fistula, they cannot be accepted as such with regard to efficiency in the second stage of *autoplasty by gradual approaches*, where it is all-important that success should be secured at the first application. Here something more than the simple or double suture is needed, in order to counteract the tendency of the vagina to recontract and to hold the edges of the fistula quietly in their extended relationship, while the healing process is going on. This is no less essential, I conceive, than the application of splints or the immovable apparatus, to keep the ends of a broken bone in a state of perfect quietude. The tendency of the vagina to recontract is not characteristic, it is true, of all cases of atresia, but there are many in which it does exist; as, for example, when the cicatrices upon both walls are extensive, and have not been completely mobilized, a condition of the parts which actually did present itself in the last case treated at the hospital, Beaujon. Here the vagina recontracted from 65 to 50 millimetres in twelve days, thus showing the extraordinary strain to which any unaided form of interrupted suture would have been subjected in holding the edges of the fistula together in the centre, where the retraction is always greatest.

Any suture, therefore, which counteracts this tendency of the edges of the fistula, during the healing process, to change their relationship, will succeed oftenest at the first application. Hence it is my honest belief, that there is no form of suture which will fulfil these indications so completely as the button wire inter-

rupted. Without it, I insist that it is quite impossible for any surgeon, however skilful he may be in the treatment of the *first* stage of *autoplasty by gradual approaches*, to ever succeed to any considerable extent in the *second*—the obliteration of the fistula; because a repetition of operations in this latter stage is not only demoralizing to the patient but to the surgeon himself, and must in the majority of cases result in disastrous failure.

But be this as it may, let the surgeon in all cases make thorough work of the first stage of the treatment; for, in the same proportion as he succeeds in that regard, will he increase his chances of success in the second, whether the simple, the double, or the button interrupted suture be employed. As for my part, I always use the third form—the *button suture*; and my convictions of its superiority to the other two for the reasons given are thorough, being the result of long experience and fair trials with the best operators of my country in the same cases and upon the same fistulæ.

Now to show the favor in which *autoplasty by gradual approaches* is held in Austria, where it has been subjected to the severest test, I may be pardoned for adding here a short extract from a manuscript letter of June 15th, addressed to me by Dr. Ludwig Bandl, of Vienna, assistant of Prof. Carl von Braun. He says: "It will no doubt please you to hear that, ever since the publication of my article upon your method of treating vesico-vaginal fistula (op. cit.) cases have continued to pour into our clinic. We have at present twelve under treatment; the greater part of which being of the most difficult character, I have myself, by permission of Prof. Braun, already operated upon two. My first case presenting a large fistula, and being otherwise difficult, I cured at two operations. My second case, thought by Prof B. to be incurable, I have operated upon twice. In the first operation I had to use a button of angular form and bent upon its axis, with nine sutures. The result was a closure of about four-fifths of the fistula. In the second operation I used four sutures and a suitable button, and reduced the size of the fistula to that of a surgeon's probe. I hope to complete the cure at another operation. My third case I expect to operate upon in a few days. Here the fistula is very large, being of a T shape. Only 1¼ ctm. of the outer portion of the urethra remains. The upper border of the fistula, after two months' preparatory treatment, has been made quite as movable as it was in your fourth case operated upon here. I hope to close the greater part of the fistula at the first operation.

"Prof. Simon recognizes the advantages of your procedure, and will soon publish an article upon the subject in the *Wiener Medizinischen Wochenschrift*, with illustrations. I hope by that time to have four cured cases to report."

NATHAN BOZEMAN, M.D.

22 RUE LAVOISIER, PARIS.
July 20th, 1876.

COOL BATHING IN THE TREATMENT OF INFLAMMATORY BOWEL AFFECTIONS OF CHILDREN DURING THE SUMMER.

TO THE EDITOR OF THE MEDICAL RECORD.

DEAR SIR:—In a letter from Dr. C. G. Comegys, of Cincinnati, Ohio, to the RECORD of July 29th, 1876, "cool bathing in the treatment of inflammatory bowel affections of children in the summer season, where fever is present," is earnestly recommended. I desire to add my testimony, based upon an experience of seven years in the practice of diseases of children, to the value of this suggestion of Dr. Comegys, as I have found *no* treatment so uniformly successful as the systematic abstraction of heat in the above class of cases. Indeed, I may venture the assertion that in a great majority of cases of entero-colitis or gastro-enteritis, attended by fever, occurring at or subsequent to dentition, antipyretic treatment, the most effective part of which being cool bathing, offers the only hope of cure. As is stated by Dr. Comegys, when we are called to these cases we find that the whole attention of the friends, and it may be the attending physician, has been oftener than otherwise, directed to the control of the diarrhœa, which is, no doubt, thought to be the sole cause of the symptoms. My experience has been, that it is utterly impossible to control the vitiated and excessive discharges from the bowels so long as fever exists, which in *every* case does not correspond with the inflammatory action in the bowels, as determined by the physical signs, and hence cannot, pathologically speaking, be considered as the constitutional expression of such inflammation. Practically considered, *it is essential that hyperpyrexia be regarded as the pathology of these affections.*

The symptoms have been well described by Dr. Comegys. In some of my cases the congestion of the bowels (which is but a part of the general condition of the circulation) has been so intense as to result in evacuations of pure blood. And it is surprising how much of this can be passed by the little patient without proving fatal. Other cases presented regular dysenteric symptoms. Without paying attention to the diarrhœa beyond giving small and repeated doses of castor-oil in emulsion with laudanum, and keeping applied tepid poultices over the abdomen while the patient is out of the bath, I have addressed my efforts strictly to the *reduction of fever*, and have found the bowel symptoms subside, *pari passu*, with the decline of temperature. If, however, diarrhœa should persist after the fever has gone, it can *now* be easily controlled by simple astringents and injections.

My plan of using the bath is not essentially different from that followed by Dr. Comegys. I am careful to, if possible, superintend the bathing myself. When unable to do this in severe cases, unless an intelligent nurse can be had, which is seldom the case, I have little hope for the patient.

A table, only sufficiently large to accommodate comfortably the body of the patient, is provided, and on this is spread first a double blanket, next a quilt, and over these a sheet is drawn and a small *hard* pillow placed at one end on which to lay the patient's head. All clothing is now removed from the body of the child, which is immediately immersed up to halfway the chest in water whose temperature is about ninety-five degrees. A cold wet cloth is then placed upon the head, which is supported by the hands, and the water of the bath, constantly poured out of small pitchers by assistants over the shoulders, back, and thorax of the patient. Cold water is gradually added and stirred into the bath, until the temperature of the latter has been lowered to seventy or perhaps sixty-five degrees, the strength of the child and the height of the fever determining the lowest point to which the cold can be carried with safety to the patient and benefit to the symptoms. When the temperature of the bath has been reduced to eighty or seventy-five degrees, the cold cloth is removed from the head, upon which, as well as the upper part of the body, the water is now poured, and this treatment is continued for fifteen or twenty minutes, when the temperature,

which in severe cases reaches 105 or more, will generally be found to have lowered to 100 or 101, perhaps less. The child is now lifted unwiped upon the table, covered with a sheet and one or two thicknesses of a light blanket, and immediately given a few teaspoonfuls of good brandy toddy (cooled with ice), which latter is systematically repeated every two or three hours, notwithstanding the high temperature, during the progress of the case. Cool ice-water is moderately allowed to slack the intense thirst and dryness of mouth which almost invariably exists.

My habit is to repeat the bath whenever the temperature has increased to 102½° or 103°, which will be found to be the case at the end of three hours in the beginning of the treatment, the intervals getting longer of course as the patient improves.

I have sometimes seen the temperature 101° when the child was placed upon the table, continue to diminish afterward until almost a fatal lowering appeared imminent. This condition is successfully treated by placing bottles of hot water around the patient, applying frictions to the extremities, and administering stimulants, these measures being suspended when the normal temperature is attained.

An important auxiliary to this treatment, but by no means essential to its success, is the administration every morning, while fever persists, of one or two decided doses of quinine. In my judgment it is not only unnecessary and (so far as reduction of fever is concerned) useless, but perhaps injurious to the nervous system of the child, to give the quinine in frequently repeated doses during the day and night. "The cause of fever is overcome by quinine most easily when its activity is lowest," which, in enterocolitis with fever (as in the fevers generally) is shown by the thermometer to be the case in the early morning. Advantage is taken, therefore, of this period to accomplish all that can be done by the use of quinine in the treatment of these cases.

Convulsions, which are but explosions of nerve force excited by the heated blood circulating around and through the nerve centres, are best controlled by the bath and by the bromide of potassium with sweet spirits of nitre in camphor mixture; while the exhaustion of the vital forces which results is avoided as far as possible by the timely administration of beef-tea, milk, and stimulants.

The above plan of treating a class of cases, by no means rare or usually satisfactorily managed, to be successful *requires much time and great diligence and perseverance* on the part of the practitioner, who is encouraged to persist in his efforts by the knowledge, that in all probability they will be rewarded by the recovery of his patient, and if not (in my opinion) he may console himself with the reflection that he has faithfully used the only philosophic means of cure.

Very truly yours,

HENRY K. LEAKE, M.D.

DALLAS, TEXAS, Aug. 4th, 1876.

FLUID EXTRACT OF ERGOT IN DIARRHŒA.

TO THE EDITOR OF THE MEDICAL RECORD.

SIR:—Having had marked success with fluid ext. ergot in the treatment of diarrhœas, I have thought it well to publish the results of my cases in the hope that others may give it a more extended trial than my limited facilities have enabled me to do.

I have based my use of this drug on the theory that it causes a contraction of the involuntary muscular fibres, and in so doing relieves the atony of the vessels of the intestinal mucous membrane and the consequent hyperæmia of the capillaries (which is always associated with diarrhœas), and thus prevents the transudation of the watery portions of the blood. In other words, it gives *tone* to the vascular walls. Be the theory worth what it may, the success attending its use has been marked. I first tried it (in my clinic at the Dispensary of the Cincinnati Hospital) in the case of a patient with chronic diarrhœa of two years' standing. No line of treatment had been able to reduce the number of his stools to less than eight per day. All other treatment was stopped, and he was given forty drops of the ergot four times a day. He came back four days afterwards saying that he was only having two stools per day, and when he next reported (ten days afterwards) he said that he has been entirely well for the past eight days. I heard from him three months afterwards, and he had had no return of his diarrhœa. He used the ergot six days.

I used it frequently after that in ordinary simple diarrhœas (giving no other medicine), and found that the patients seldom required beyond three doses (twenty drops each), and never more than six.

While stationed at Fort Wadsworth, N. Y. Harbor, last summer, I used it in twelve cases (the number of stools varying from eight to twenty in the twenty-four hours), and in but one case was I obliged to give more than three doses to each case. In that one case it failed to modify the diarrhœa, but that may be accounted for by the fact that the ergot had been kept on hand for a long time.

Since I have been stationed at this post I have had but three chance to try it. In one case it failed (case of chronic diarrhœa of four years' standing); in the second one my patient refused to take more than one dose on account of its unpleasant taste; in the third case it succeeded.

I offer this with the hope that others may give it a more extended trial than I have been able to do, and that they may publish their results.

E. T. COMEGYS, A.M.,
Ass't. Surg. U. S. A.

FORT DUNCAN, TEXAS.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from August 13th to August 19th, 1876.

HAPPERSETT, J. C. G., Surgeon. Assigned to duty as Post Surgeon at Fort Hamilton, N. Y. H. S. O. 157, Mil. Div. of the Atlantic, Aug. 16, 1876.

DE HANNE, J. V., Asst. Surgeon. Leave of absence extended for 20 days. S. O. 158, Mil. Div. of the Atlantic, Aug. 17, 1876.

PRICE, C. E., Asst. Surgeon. To accompany battalion of 4th Artillery to Cheyenne, Wyo. T. S. O. 111, Mil. Div. of the Pacific, Aug. 11, 1876.

HOUSE DRAINS IN OLD LONDON.—The *Lancet* says: We believe there is no exaggeration in saying that the house drainage of nearly two-thirds of houses in the older London parishes is defective. The drains originally constructed of brick, through age and the undermining activity of rats have become extensively pervious, and the domestic sewage passes out freely into the basements, and but a small portion reaches the sewers.

Medical Items and News.

Contagious Diseases.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending August 19, 1876.

A Useful Diuretic.—A French surgeon in Algeria has been very successful in the use of the *Juncus Acutus* as a diuretic. About twenty stems are subjected to decoction, both the white and green parts being used.

Plasma Tubes of the Human Skin.—Axel Key and Gustave Retzius give a brief statement of the results of their researches on the plasma passages of the skin, especially of the superior extremities. A more complete account of their studies will be found in their work, now passing through the press, "On the Anatomy of the Nervous System and the Connective Tissue." They mention the fact that, besides the true efferent lymphatic vessels, they have discovered in the skin an extended system of large plasma passages communicating with the lymphatic vessels mentioned, and resembling those which they have mentioned and drawn in the last fasciculus of their work, as existing in the mucous membrane of the nose. In the deepest parts of the skin, the plasma passages around the constituent parts (sweat-glands, hair-bulbs, etc.), are relatively large and wide; in the external portions they become more slender but abundant, and they form a fine net-work in the papillæ. They are not limited by the epidermis, however, but cross the papillæ in many places and penetrate into the rête Malpighii. Our authors have, in fact, succeeded in injecting in the rête Malpighii a fine net-work of plasma tubes with compact meshes which fill the intervals between the various cellules in every direction as far as the corneous layer. The intercellular injection is arrested externally by the latter cell layer; but there is a system of passages at the surface of the skin which are so disposed that the injection penetrates the excretory ducts of the sudoriparous glands. With regard to the plasma passages of the rête Malpighii, our authors remark that M. Bizzozero endeavored, several years ago, to prove that the spines of the cells of the rête do not cross each other like the teeth of two wheels, but that these "stachels and riffs" from adjacent cells hang together by their points, leaving small spaces and passages between them. It is quite evident that it is these intervals which K. & R. have injected in the rête Malpighii, and which communicate with the plasma tubes of the dermis itself.—*Nordiskt Med. Arkiv.* Vol. 8, No. 5.

Contributions to the Neurology of the Epidermis.—Dr. J. G. Ditlersen has found in the skin of frogs numerous fasciculi of vertical fibres, called perforating, starting from the subcutaneous cellular tissue, which is rich in nervous plexuses, and traversing the entire dermis as far as its superior limits. These fasciculi contain nerves, connective tissue and often fibre cells. The nerves, which are surrounded by a sheath of connective tissue, leave the latter at the upper margin of the corium and advance into the epidermis under the form of a compact fasciculus of fibres, provided with nuclei, but deprived of medulla. The bundle crosses the entire epidermis as far as the corneous layer, where it appears to attach itself in an infundibuliform depression. By means of a higher magnifying power (for example, Hartnack, Obj. viii.) one sees that each nerve fibre, after its entrance into the epidermis, bends somewhat in the form of a Roman S outwards and upwards, before terminating in a terminal cell. The most external fibres of the fasciculi terminate in their respective nerve cells as soon as they have entered the epidermis, the intermediate fibres in the middle layers of the epidermis, and the central fibres after having arrived at the two layers of the corneous cells. It should be remembered that the epidermis of the frog is composed of about six or eight layers; the inferior ones are formed by vertically elongated cells, the intermediate layers by round or transversely elongated cells, and the superior layers, that is, the two corneous layers, by flat cells. If it is also remembered that the terminal nervous cells of the different layers of the epidermis, resemble very much in form and aspect the proper cells of the epidermis, we shall be less astonished that the remarkable arrangement above described has remained unperceived up to the present time. In fact, the peripheral terminal cells, that is, those which are situated nearest the corium, stand over the latter in an almost vertical manner, and are spear or chisel shaped. The middle ones are more curved outwards and are larger and leaf shaped. The most superficial cells leave the nerve fibres at an obtuse or almost right angle; like the surrounding corneous cells, the borders of which they touch, they are very flat. The terminal end of the nerve cylinder thus formed does not become attached to the inferior surface of the corneous layer, as appears with a lower magnifying power, but traverses the latter as far as the free surface of the epidermis. In horizontal sections of the epidermis, the transverse sections of the cylindrical fasciculi of the nerve cells appear as large circles filled with irregular sections of terminate cells. In sections of semi-macerated preparations, the ordinary cells of the epidermis may be removed by means of a brush, when the nerve cells will be seen attached to their respective nerve fibres. One may then, with a certainty which leaves nothing to be decided, follow the communication between the cells and the nerve fibres, and the latter may be traced down into the deep layers of the corium. These structures are disseminated throughout the entire skin of the animal; they are more highly developed and in greater numbers in the dorsal region. Undoubtedly they form the organs of sensation of the skin.—*Nordiskt Med. Arkiv.* Bd. 8, No. 4.

Plague and Ague.—A physician of Bagdad states, that in the first stage of the plague it is impossible to distinguish it from ague. Only when buboes appear, which is a characteristic of the former disease, can a diagnosis be made. Quinine has no effect upon the plague; in fact, in the latter stages, it is believed to be positively harmful.

Ventilation of the House of Congress.—The Board to whom was referred the question of Improved Ventilation in the House, has recommended that an increased amount of air be supplied by cutting a number of openings in the floor and inserting extra registers.

Original Communications.

SOME REMARKS UPON THE RELATIONS BETWEEN ANOMALOUS REFRACTION OF THE EYES AND CERTAIN FUNCTIONAL NERVOUS DISEASES,

WITH A TABLE SHOWING THE REFRACTIVE CONDITION OF THE EYES IN FIFTY-FOUR CASES OF EPILEPSY.

By GEO. T. STEVENS, M.D.,

ALBANY, N. Y.

In a paper on Chorea, read before the New York Academy of Medicine, June 15, 1876, I announced the proposition that not only was chorea the result of anomalous refraction of the eye, but that, beyond any and all other causes combined, other functional nervous diseases are dependent upon refractive lesions.

It will be conceded that there is a large class of persons who are *predisposed* to neuroses of various forms, and in whom comparatively trifling immediate causes give rise to intense neuralgia, to headaches, to hysteria, or to some other form of functional nervous disturbance.

The condition observed in this class of persons has been called the *neuropathic predisposition*; a predisposition clearly of great interest and importance, but of which nothing beyond its existence has been known. No one has ever shown in what the anomaly consists.

It was my purpose, in the paper on chorea referred to, to show that in that form of nervous disturbance so clearly defined, refractive lesions constitute the predisposition to the disease, as they often do the immediate cause, and at the same time I assumed the broader ground that these same refractive lesions are the prevailing cause of neuroses.

This view may perhaps be better expressed by saying that, almost universally, refractive lesions constitute the *neuropathic predisposition*, and that to the refractive condition of the eye we must, as a rule, refer the tendency to the development of functional nervous diseases.

I have now examined a very considerable number of cases belonging to this class of diseases, with reference to the relations between them and the refractive conditions of the eye, and find thus far extremely rare exceptions to the principle above stated.

Thus, in more than one hundred cases of severe recurring headaches, including several which were clearly of the form called migraine, refractive anomalies have been found without exception; in more than seventy cases of chorea the rule holds good, and in seventy cases of epilepsy only three were free from refractive lesions, and in two of these deep physiological excavation of the optic nerve existed, a condition which often gives rise to a most troublesome form of asthenopia. Of numerous cases of hysteria and of neuralgia not of traumatic origin, all possess refractive errors, and the same may be said of many less defined forms of functional nervous disturbances.

In the table below will be found the refractive condition in fifty-four cases of epileptic insane persons. Numbers 1 to 49 inclusive were inmates of the Willard Asylum for the Insane, and I am indebted to the courtesy of Dr. Chapin, the superintendent, and of his able assistants, Drs. Wise, Nellis, Carson, and Hopkins, not only for the opportunity to examine these cases, but for their great kindness in affording every facility for making what, under the circumstances, was a difficult series of examinations.

The cases numbers 49 to 54 were inmates of the Marshall Infirmary of Troy, and my thanks are due to Dr. Lomax, the superintendent, for his kindness and assistance.

Several of my medical friends have referred cases of epilepsy in their private practice to me for examination of their eyes. Some of these are now under observation, and the results of the correction of the refractive evils will be duly reported.

The results given in the table are necessarily, under the circumstances, in some cases less technically exact than an ophthalmic surgeon would expect to obtain with his private patients at his office, yet they are materially correct.

In most cases one eye was atropized, and when the refraction was determined solely by the ophthalmoscope—as it was necessary to do when the intelligence of the patient was not sufficient to enable him to answer questions correctly, or at all—the eye examined was fully under the influence of atropine.

In many of these cases the optic disk and retina exhibited a noticeable degree of hyperæmia, a condition to which considerable importance has been attached in cases of insanity, but which I believe to be only the hyperæmia which the ophthalmic surgeon habitually finds in his cases of astigmatism and hypermetropia. The amount of sight was recorded after correcting the refractive errors. It will be observed that in only a small proportion of the cases is the amount of sight more than $\frac{20}{30}$.

(Explanation of symbols: H., hypermetropia; M., myopia; Ah., hypermetropic astigmatism; Am., myopic astigmatism; H. Ah., hypermetropia with hypermetropic astigmatism, etc.)

PLACENTAL DELIVERY AND UTERINE INVOLUTION.

By EZRA M. HUNT, M.D.,

METUCHEN, N. J.

THE management of the placenta seems to have admitted about as many shades of opinion and diversity of practice as obtain in the management of the fœtus itself. Twenty-five years ago the direction of most of the leading professors was to leave its expulsion to nature, or await at least for an hour the completion of the process. This direction, like many other absolute rules, is mischievous just because time is a relative thing. The department of obstetrics does not admit of such close mensuration. Time is an element to be considered because it has some general relation to the usual proximity of the various processes, but is nevertheless liable to many variations to be watched for by the practitioner. The supine position, the absence of motion and other incidents disturb the law by which, under other circumstances, the placenta might be voided. The fact that it will remain so long partly in the vagina and partly in the uterine cavity, and that its expulsion can be accelerated by friction, coughing, pressure, change of position, etc., shows how amenable it is to artificial aid, and so far indicates that this is to be employed if there are no complications arising therefrom. We are inclined to think that of all the things in usual obstetric position and subjective condition which nature entirely unassisted is least likely to do perfectly, complete placental expulsion stands foremost. This is often attributed to feeble vaginal contraction, but often there is uterine inertia as well. Books and sometimes teachers do not emphasize this. Yet we know excellent practitioners who uniformly give a dose of ergot immediately after the birth of the child. We believe that a vast majority practically do more towards the delivery of the placenta in most cases than its mere removal from the vagina after its complete expulsion from the uterus.

We are led to this remark by a recent case, which at least illustrates what not to do.

A woman was delivered of her fifth child without medical aid, and relied upon a neighbor, whom she told she would call upon afterwards to assist, if need be, with the placenta. The friend considered herself efficient in pulling, and so as the placenta did not come, pulled upon the cord. There was also some

evidence that the fingers had been introduced into the vagina and through the os uteri. Several clots of blood had been scooped out, which had only served to renew a uterine hemorrhage, not gushing, but still of moment. When called, I found upon examination a distended womb, great pallor, and blood clots in the lower cavity of the uterus, but could feel no cord or placenta. I at once made further inquiry, and had a basin brought me full of clots, with a cord two feet in length lying amid them, which had been broken off close to its attachment with the placenta. On introducing the hand and making pressure with cold over the womb, I found the cavity filled with blood, but no placenta apparent. Further introduction revealed hour-glass contraction about midway of the uterine cavity, through which steady and careful pressure with the cone-shaped hand brought us to the placenta, not adherent, but lying loosely in the upper segment. As I had been summoned in passing, several miles from home, no ergot was at hand, but there was no sudden increase of hemorrhage, and the uterus began to contract with the removal of the mass. There had been no complication in the case at the start, but the partial introduction of the hand, and the severe pulling upon the cord before the placenta had fully separated, had excited the hour-glass contraction, at least this is the probable explanation.

We are more and more impressed in midwifery practice how much the uterus needs careful regard after the birth of the child. Promiscuous and severe pressure on the one hand, and unguarded laxity on the other, are both injurious. The physician needs soon to know by outside encompass how much contraction has taken place, and to know by examination the position of the placenta. The contraction is the best test of mode and time of procedure, except in those cases where contraction needs to be excited by the introduced hand. There is in many a placental delivery, trouble arising from a failure to remove the placenta just at the time when the uterus is partially acting, and when there is need of aid by a drink of cold water, coughing, reflex irritation, or such oscillating movement or such introduction of the hand as shall envelope rather than pull, and thus aid the expulsive process. Rupture of the cord is very rare with proper management, and yet possible. Some time since, in a severe labor, we had severed the cord and were busy in striving to revive an asphyxiated infant. On returning to the patient in four or five minutes, we found a flushed face changed to entire pallor, and the uterus had suddenly distended. A slight pull upon the cord brought it away ruptured only a little from the place of insertion. Amid a column of hot blood we found the placenta at the very fundus, mostly detached and non-adherent. The only possible strain there had been upon the cord was in the last rapid expulsive effort upon the child after a long labor. A cord about thirteen inches in length, and a placenta as yet in the fundus, had by a jerk torn the fibres and caused an internal hemorrhage, which came very near proving fatal. In a recent case, just at the birth of the child, we found it impeded in its expulsive change of position, and felt the cord tense and rigid as the child passed as far as the umbilicus. In memory of the other cases, the cord was promptly cut. When in due time the placenta which was attached at the fundus was delivered, the cord was found just twelve inches long. In another case the next day, it was thirty. These variations in length are not unusual. Generally, even with a short cord, no contingency arises from this; but where the attachment of the placenta is at the fundus, and the expulsion accomplished rapidly while the placenta is closely adherent and the uterus does not contract down rapidly from the upper segment upon the departing fœtus, the accident may easily give rise to hemorrhage, either by violently separating the placenta or rupturing the cord. That is a good sentence of Leishman's, which says: "One hand is to be placed over the fundus uteri, which is to be gently pressed and followed in its descent by the hand, a practice which tends to promote the speedy separation of the placenta," p. 274. While the cord is available as a guide, it is always to be remembered that the most natural escape of the placenta is edgewise, and not that of a mushroom pulled by its stem. It is also to be remembered that the contraction which separates the placenta does not always insure its complete expulsion through the os uteri. The normal action of the uterus in delivery and after, is that of alternate contraction and relaxation. The presence of a separated placenta in the uterus fairly contracted, often excites sufficient action to aid in expulsion, but if not, its presence is favorable to hemorrhage. Its removal overcomes this both by withdrawal of the mass and the reflex irritation of the hand, "which is often aroused by digital examination, which seems to excite the nerves that are distributed in some abundance to the tissues of the perineum." (Leishman, p. 570.) There may be contraction of the upper and lateral segments of the uterus, and yet the cervix, os, or vagina permit the placenta to remain. The judgment of the practitioner is required in each case, whether to accomplish removal in a very few minutes or be patient under long delay. Books are rightly conservative, because caution is the better part of valor. But we doubt whether "the practitioner should wait fifteen or twenty minutes before passing the finger into the vagina, to ascertain whether the separation of the placenta is complete," nor, if feeling the side of the placenta and not the cord, he should wait ten or fifteen more for separation.

Even the complete expulsion of the placenta is not always the test of the safe contraction of the uterus. We like the excellent remarks in a recent brief review in the MEDICAL RECORD (July 8, 1876), of Robert's Practice of Midwifery. The reviewer, after objecting to a limitation of the third stage of labor to the separation and expulsion of the placenta and membranes, says: "We believe that it would be much safer to teach that the third stage of labor necessarily includes *permanent uterine contraction*." There is not enough thought about this or about that change called "involution of the uterus," which, though not complete for a long time in a normal case, is rapid during the first week. From its weight of one and three-quarter pounds, the uterus has to hasten back to two or three ounces. Its cavity of 400 cubic inches is to come back to one or two, and its surface of 350 to six square inches. The reduction of its hypertrophied lining, the fatty transformation and absorption of its multiplied fibres, the desquamation of its internal surface and development of new membranes, are reparations and readjustments almost as wonderful as its far more speedy developments (see Barker on Puerperal Diseases, page 93). When contraction and involution take place properly, in one week the organ cannot generally be felt above the pubes, and more than half the work has been accomplished. Any arrest of this process in any form is fraught with no small risk. The uncontracted cavity will not remain a vacuum, the arrested involution of fibre will be supplemented by hypertrophy of tissue, secretions will be contaminated, and metritis in some of its milder or more pronounced

forms is imminent. In those insidious cases which too often suddenly make the practitioner conscious of serious invasion, the condition of the uterus as to contraction and involution is among the earliest informants. Delayed involution always is the signal for special watchfulness and close inquiry. A recent case will illustrate.

Mrs. O., a primipara, had a labor entirely natural of about six hours' continuance, and ending at two A. M. I found her at eight A. M., as comfortable as could be desired. The uterus had contracted as well as usual, although the after-pains were light; there was no hemorrhage, and nothing in any way unusual in the case. During a two days' absence she was well cared for by a medical friend. On the morning of the fourth day, I found her very comfortable, but with greater fulness than usual. This was not abdominal, but owing to defective uterine contraction. Yet as there was no hemorrhage, no interference with usual discharges, and a good general condition, it did not excite much anxiety. At noon that day she experienced a severe rigor. There was no pain, and as the breasts were rapidly distending, I was disposed to connect it with the lacteal secretion. An early visit the next morning showed a pulse still rapid, and but little exacerbation. The thermometer, to my great surprise, recorded 105°. A second thermometer did the same, and trying it on two or three well persons, I found that my long-used instruments had not deceived me. Distention had increased so that the uterus reached well up to the gastric region. Pulse was 120, but there was absence of other serious symptoms. There was no expression of pain. Careful palpation and examination showed but very little tenderness, and this confined to a spot not larger than a dollar near the right inguinal space. Aconite and nitre were freely administered. Ice was used internally, and frequent sponging externally to moderate heat. A turpentine stupe was applied over the uterus till it produced redness and a slight vesication. Injections of carbolic acid were ordered per vagina. A Dover's powder was given at night to secure sleep. The next morning, June 10th, temperature had reached 106°, but fell to 105¼; at night a dose of quinine being given as an antipyretic. The case was regarded as one of metritis supervening upon imperfect involution and tumefaction of the uterine tissues. The plan of treatment was chiefly that indicated by Fordyce Barker, in his excellent chapter on Puerperal Metritis.

On the fourth day from the chill, the temperature varied from 104¾ to 105°, with pulse from 110 to 120. This high temperature continued to surprise me because the patient suffered little pain, took food readily, and did not give the impression of alarming sickness, except in rapid breathing and complaint of extreme heat. Pressure, however, revealed more soreness over a circumscribed portion of the uterine walls, where the first pain had been manifest. Aconite and nitre were freely administered, and twelve grains of quinine prescribed per day in two doses. The midday temperature fell to 103°, but rose in the evening again to 105°, with no decrease in frequency of the pulse. The next morning I found temperature 101 rising to 103° during the day, and the general symptoms were not so phlogistic. Nourishment was well received, and restlessness easily controlled by an evening opiate. There was a nervous mobility and discouragement which was troublesome. The condition of the uterus was carefully guarded each day, efforts being made to reduce its size by pressure, by bandaging two or three times each day by myself, and the free use of carbolic syringing. I am sure much benefit was derived from careful manipulation, and that involution was much aided thereby. There was improvement so soon as the uterus commenced to diminish in size, and convalescence was fully established about the ninth day from the chill. Improvement kept very perceptible pace with the subsidence of the uterine tumor. An examination of authorities surprises one to find how little is said upon the subject of uterine involution. Some cases in practice have made us to feel that it is the business of the practitioner to know not only that the uterus has contracted after labor, but at subsequent visits to examine the abdomen, with the purpose of determining the bounds of the uterine tumor with precision. It is a more important indication of the puerperal condition, and a source of information more valuable than estimated by some practitioners. Even where there is no chill, no revealed metritis, no cessation of lochia, there is often bad "getting up" from retarded involution. This may be much relieved by ergot, nux vomica, quinine, by external palpation, and, where needed, by turpentine stupes and carbolic injections. We have manifold wet preparations and lithographs of the condition of the womb in its development, and of the fœtus and membranes it contains. It would be an aid in the subsequent widwifery, if the practitioner could trace the daily changes from the time of fœtal delivery to the point at which the process of involution is completed. The chronic results of incomplete involutions we have in the last few months had the opportunity to trace in a prolonged case of metritis and pelvic cellulitis so typical as to add to our diligent watchfulness to avoid such results. We are convinced that the attention of the practitioner needs to be more thoroughly fastened upon the third stage of labor, and upon those sequelæ connected with the reparative and reconstructive return of the uterus to its unimpregnated state.

Reports of Hospitals.

BELLEVUE HOSPITAL.

NOTES OF PRACTICE AND ITEMS OF TREATMENT.

SUBACUTE PLEURISY—SYMPTOMS REFERRED TO THE ABDOMEN.

THE chief items of interest in the case were the absence of initial symptoms and the diversion of the attention from the real seat of the disease, by the fact that all the pain was referred to a region low down in the abdomen. A male patient, æt. 35, a glass-blower and a moderate drinker, had been sick about twenty days. He was attacked with a moderately severe pain just above the left hip, paroxysmal in character, occurred independent of cough, extended toward the median line and upward over the chest; and after about twelve days it became so severe that he was obliged to cease work. The patient described the pain as a burning pain, and was unable to continue his work on account of its constancy and severity upon the left side of the abdomen, and, at the end of the twelve days, shortness of breath interfered with his blowing. At the time of the examination his pulse was 118, respiration 36, temperature 100¾ F., but was 102¾° F. when admitted. The left pleural cavity was filled with fluid, of which ℥ xii. had been removed, hoping thereby to remove the pressure from

the absorbents sufficiently to permit them to take care of the fluid without further surgical interference. Full diet, half-drachm doses of syr. ferri iodid. three times a day, and, were it possible, champagne with his dinner, was the plan of treatment recommended. A blister was not objected to for a patient having the strength this man had, but was not specially commended unless there was considerable pain in the side. The chief interest in the case consisted in the obscurity of the symptoms, the inability to diagnosticate the disease independent of physical examination, and the abdominal pain. The visiting physician remarked that, in children suffering from pleurisy, the pain was quite commonly referred to the abdomen.

SUBACUTE PLEURISY—EXCEPTION AMONG THE PHYSICAL SIGNS—SUGGESTIONS CONCERNING PARACENTESIS.

In the case before us there was flatness upon percussion from an inch above the angle of the scapula downward; the apex of the heart was beating nearly in the median line, and the voice sounds were heard to the bottom of the pleural cavity. The bronchial voice heard over the entire left chest behind was regarded as exceptional among the signs indicating the presence of fluid in the pleural cavity in adults, but it was quite commonly present in children. The special interest in the treatment centred upon the question of paracentesis. The visiting physician was of the opinion that experience taught us that tapping was not to be resorted to unless it became absolutely necessary; that is, that efforts should be first made to remove the fluid by other means, such as counter-irritation, tonics, diuretics, etc., and when these failed, after being faithfully tried, then paracentesis. For there was an uncertain element in prognosis in not knowing exactly what the character of the pleurisy was; not knowing exactly what condition of lung was present. If a patient who had a predisposition to phthisis acquired acute pleurisy, the pleurisy would have an entirely different anatomical character, and would run an entirely different course from that pursued by an acute pleurisy occurring under other conditions. Those were the cases which were apt to resist medical treatment, and when the chest was tapped did badly, and died with the lesions of phthisis in the lungs, together with the peculiar form of pleurisy commonly found in that class of cases, namely, empyæmia.

HABIT OF TAKING OPIUM—INORDINATE USE OF THE HYPODERMIC SYRINGE.

The patient, formerly an orderly in the hospital, began the use of morphia subcutaneously for the relief of pain, and had continued its use for two years. He had employed Magendie's solution, and had increased the quantity until finally he was taking three hundred minims every twenty-four hours: the largest number of injections taken in the same length of time was twelve. The appearance of the man's body and thighs was very striking, for they were studded with discolored spots, cicatrices from old punctures, and localized abscesses, some of which were surrounded with erysipelatous inflammation. The appearance was nearly the same upon both the posterior and anterior aspect of the trunk; for, failing to find sufficient uninvaded territory upon the anterior portion, he had learned to thrust the needle of the syringe into his back. At the time of our visit he was suffering severely from the effects of the discontinuance of the opium, which had been cut off entirely and at once.

TREATMENT OF CHRONIC DYSENTERY.

For example, a man has three, four, or five discharges daily: First, with reference to diet, milk is the best article of food that can be employed. This article is very frequently condemned by the laity when suggested in connection with the treatment of diarrhœa and dysentery; and truly it is liable to aggravate the case unless properly administered.

Caseine is exceedingly indigestible, and if it remains unchanged in the alimentary canal it will increase the severity of all the symptoms. When milk is administered, therefore, it should always be combined with an alkali; for thus combined it is much less liable to disagree with the patient. A very convenient alkali is the liq. calcis saccharate, which diluted with water, may be taken in half-drachm doses, after taking the milk. Meat usually agrees with the patient, because it possesses a large amount of nourishment in a small bulk. Meat without fat should be used, and it is most serviceable when taken raw, scraped, and salted a trifle; raw meat may be the only thing with which the life of a child suffering from acute dysentery can be saved. It may be given in teaspoonful doses every two, three or four hours, according to the severity of the case. Milk should not be used at all for children, during the earlier part of an attack of dysentery. Among the meats, mutton is most easily digested, beef next, and poultry third. Potatoes always work badly in severe cases of chronic dysentery. Turnips, beets, cabbage, and those articles which contain woody fibre, are not well borne. In some cases, rice is the only article belonging to the starch group that can be employed. Certain patients can take eggs with advantage, others cannot. If bread is used, it should be stale.

A careful regulation of the diet of this class of patients is competent to do more than any one element towards effecting a cure. They should be kept in bed, and only a small quantity of food taken at any one time.

ITS MEDICINAL TREATMENT.

The first indication is to stop the irritation in the lower part of the bowel. If ulcerations are present they should be treated topically. It occasionally happens that all the trouble arises from a single ulcer. In some cases the ulcers cannot be found; and again, the case may not be cured after the ulcers have been found and healed by means of local applications. For, there may remain a peculiar irritable condition of the nerves which will keep up the discharges from the bowels almost indefinitely. To allay such irritability of the nerves supplying the lower part of the bowel, administer injections containing free doses of the bromide of potassium. Such injecions are especially serviceable in the treatment of the dysentery among children. Laudanum may be combined with the bromide if an anodyne is required. The remedy should, if possible, be used locally.

Injections of carbolic acid answer a very good purpose for correcting offensive discharges, but not to effect a cure. Astringents, as a rule, do not work well in the treatment of chronic dysentery. Castor oil is a very serviceable remedy in the treatment of either the acute or chronic form of the disease.

Oils have a tendency to produce watery discharges from the mucous membranes with which they come in contact.

Linseed oil is eliminated by the respiratory mucous membrane. Castor oil passes out through the mucous membrane of the alimentary canal, and produces free watery discharges. The action of castor oil then is to change the character of the intestinal secretions from an exceedingly viscid, albuminous, fibrinous quality, to a much more watery, and also changes the charac-

ter of the inflammation from one having a tendency to produce pus, to one which is accompanied by a more watery discharge, and one which will subside of its own accord within a short time. The theory concerning the action of this remedy is that it is first cathartic, and then astringent; but the fact in practice is, that the remedy has more control over dysentery than any other single article in the materia medica. In the first place follow the cathartic dose of castor oil by a full dose of laudanum, and then commence the steady treatment by using two drachms of the oil, combined with twenty drops of laudanum, mixed up with mucilage of gum arabic, and administered every two, three, or four hours.

The majority of acute cases in children will yield to castor oil and laudanum combined, and so it is with chronic dysentery occurring in adults. It may also be used as an adjuvant to other measures.

One peculiarity attending the use of castor oil combined with laudanum, is that the patient certainly gets more sleep than when laudanum is administered alone.

Chalk, opium, and astringents usually fail; and bismuth does not, as a rule, have much control over chronic dysentery.

Acetate of lead is a remedy which has acquired considerable reputation in the treatment of bowel affections, but in chronic dysentery it is much more effectual when given by enemata than when given by the mouth. Not more than from two to four grains should be used at a dose, and the menstruum should not be more than three ounces in quantity. Water may be used as a menstruum, and an injection given immediately after a passage. These injections may also contain laudanum. Acetate of lead is a local anæsthetic, as well as a general astringent.

Progress of Medical Science.

A Case of Athetosis.—Dr. Bernhardt, of Berlin, reports a case, which agrees in all essential particulars with the description of the disease to which Hammond has given the name of Athetosis. The most noticeable symptoms are restless movements of the fingers, and less markedly of the toes on the right side, the rest of the extremities being entirely unaffected; slight equino-varus position of the right foot with tension of the tendo Achillis, and flexion of the toes; partial anæsthesia of the right side of the body, with slight loss of power on the same side; and hypertrophy of the muscles that are in constant action. The disease has lasted nearly eight years, and all the methods of treatment tried have proved utterly useless. These symptoms appeared first during recovery from some acute disease, probably one of the exanthemata, which confined the patient to his bed for several weeks, when he was four years old. His parents were both healthy, but one brother and one sister suffered from chorea, which proved fatal to the brother.

Dr. Bernhardt was particularly struck with the resemblance this case bore to hemichorea, and thinks it should be classed with the disease that has recently received the name of post-paralytic chorea (Weir Mitchell). In this disease, according to Charcot and Weir Mitchell, a choreic condition is developed in the paralysed limbs of patients, who have suffered for a long time from hemiplegia. Charcot has shown by post-mortem that the seat of the disease is on the opposite side of the brain, in the posterior part of the thalamus opticus and its immediate neighborhood, while Bernhardt agrees with Hammond and Charcot in theoretically considering the lesion of athetosis to be a sclerosis of the corpora striata or optic thalami.—*Virchow's Archive*, May 27th.

Two rare Dislocations.—Dr. Gallez recently reported to the *Académie Royale de Médecine de Belgique* two cases of very rare dislocations. The first was a luxation of the symphysis pubis. The patient, who was 35 years of age, and by occupation a puddler in an iron-foundry, was in the act of throwing a heavy mass of iron into a furnace, when his foot slipped and he experienced a severe pain and a cracking sensation in the pubic region. Although walking caused him much suffering, he continued to work for five days, before he sought medical advice. When he presented himself to Dr. Gallez, palpation showed that the left pubis was displaced downwards, forwards and outwards, and formed a tumor under the integuments. The spine of the pubis on the left side was a finger's breadth lower than that of the right side. The articular surface was directed forwards and outwards, its posterior border resting on the anterior border of the descending ramus of the right pubis. The pubis moved when the thigh was flexed and adducted. The bladder was not affected. The patient resumed work on the following day, and would only consent to wear a bandage, which did not however suffice to retain the bones in proper position.

A few days later, Dr. Gallez was called to see a laborer, aged 53 years, who had fallen violently on the edge of a cylinder. The patient fell on his epigastric region, and experienced at once a pain so severe that he was obliged to leave his work. Examination revealed a tumor as large as an almond over the lower end of the sternum, which, when pressed upon from above, moved downwards into the position of the xiphoid appendix; the pain on movement was severe, and a bruit was produced similar to the dry click of the lid of the small box used for wax-lights. Dr. Gallez was able to reproduce and reduce the luxation at will, and finally retained the appendix in position by means of a compress and adhesive plaster. No special symptoms were excited, and the patient resumed work four days later. There are only two other cases of luxation of the xiphoid appendix on record. They were both reported by Malgaigne, and in both the luxation was inwards and was accompanied by vomiting. In Dr. Gallez's case the posterior chondro-xiphoid ligament was ruptured, and the anterior ligament carried the cartilage forwards. This is probably a unique case of *pre-sternal dislocation of the xiphoid appendix*.—*Le Mouvement Médical*, June 10, 1876.

Sparkling Synchysis.—This singular affection of the eye was first described in 1828 by a physician of Périgueux; in 1844 Desmaires proved that it was due to the presence of flakes of cholestearine in the vitreous humor, and in 1850 Blasius tried to prove that these flakes were situated in the crystalline capsule. M. Poncet has lately had an opportunity to examine two eyes in which M. Trelat had discovered the existence of sparkling synchysis during life. The eyes were preserved in Müller's fluid, and the following are the results of the examination:

1. The floating particles do not consist entirely of cholestearine; crystals of cholestearine and of tyrosine, and phosphatic globules enter into their composition. These last consist of crystallized phosphates on which crystals of tyrosine are sometimes deposited.

2. Sparkling synchysis is a lesion of the vitreous

humor; when the lens has undergone an alteration, it is always secondary to that of the vitreous humor.—*La France Médicale*, May 13th.

Acute Glaucoma cured in a few hours by Paracentesis of the Sclerotic.—At the séance of the *Société de Chirurgie*, on May 10th, M. Le Fort read a paper in which he presented a new theory of glaucoma. He holds that acute glaucoma consists in a secretion of serosity by the external surface of the choroid; this fluid is imprisoned in a space comprised between the sclerotic and the choroid, and closed in front by the outer border of the iris, and behind by the optic nerve; the fluid accumulated in this space pushes the lens forward, and the choroid and retina inward; hence the excavation of the papilla, an excavation only apparent and due to the pushing forward of the retina around the papilla. His treatment consists in puncture of the sclerotic to allow the fluid to escape, and he has twice cured acute glaucoma by this operation. In the first case, the puncture was made between the superior and external recti, and gave exit to a serous fluid. On the next day the patient could read ordinary print, and fifteen days later he left the hospital cured. In the second case, the puncture was made in the same situation, and a few drops of a serous fluid, but no vitreous humor, escaped. On the next day the patient could read No. 8 of Snellen's scale, though before the operation he could scarcely distinguish the characters of No. 30.

In the discussion that followed, M. Perrin admitted that the facts reported by M. Le Fort were very interesting from a clinical point of view, but he could not accept the latter's theory of glaucoma. M. Le Fort did not bring the results of ophthalmoscopic examination to the support of his theory, neither did he indicate the presence of that typical symptom of acute glaucoma, contraction of the field of vision. M. Perrin admitted that the results of ocular paracentesis are incontestably good in cases of marked intraocular tension, but pointed out that the operation of Hancock for acute glaucoma has been completely abandoned in England. In closing the discussion, M. Le Fort did not attempt to defend his theory, but called attention to the immediate and excellent results of the operation in the two cases cited. He thought that his operation, which is performed in the middle of the sclerotic, should not be assimilated to that of Hancock, which consists in a puncture at the junction of the cornea and sclerotic, just over the ciliary circle, and in a very vascular region. Puncture of the sclerotic is not dangerous, and may be tried before resorting to iridectomy.—*La France Médicale*, May 13th.

Possible source of Error in the Nitric Acid Test for the Biliary Pigment.—Gmelin's test for the coloring matter of the bile in the urine consists in letting a few drops of nitric acid gently flow down the side of the test-tube which contains the urine. The acid falls to the bottom of the tube, and by diffusion reaches the biliary pigments, which undergo the usual coloration, producing yellow, green, blue, and red zones in the fluid. M. Cazeneuve warns us against a possible error in this experiment. It is well known that when alcohol and nitric acid are mixed, the former causes a transformation of the latter into nitrous acid, with the immediate production of the very volatile nitrous ether. This reaction takes place without any coloration. If, however, the acid be allowed to flow slowly down the side of a test-tube containing alcohol, it will fall to the bottom, and the two fluids will then react slowly on one another. At the end of a minute a magnificent greenish-blue zone appears, with a yellowish-green zone below it, and, a few moments later, a reddish zone above it in the superjacent alcohol. Here the nitrous acid formed from the nitric acid appeared at the same time, partly as a hypoazotide—hence the blue, green, and yellow tints—and progressively etherized the alcohol; in the end all coloration disappeared. It is important, then, when using Guvellin's test for the biliary pigment, to be sure that the suspected fluid contains no alcohol.—*La Tribune Médicale*, June 4th.

Sudden Death in Phlegmasia Alba Dolens.—At a recent meeting of the *Société de Médecine de Strasbourg*, Dr. Roth reported the following case, which had occurred on that very day. He was called to see a patient who had been confined fifteen days before, and was suffering from phlegmasia alba of the left leg. This patient hardly considered herself sick at all, and had been up part of the day. When the doctor arrived she was sitting up in bed, conversing with her attendants. M. Roth found a small clump of varicose veins in the middle of the left thigh, and a tumor of the same nature on the leg. In examining this latter tumor he passed his hand lightly over it, when the patient suddenly complained of feeling badly, fell back on the bed, turned her head to one side, drew a few deep inspirations, and died in a few moments. The Doctor asked the Society if this almost instantaneous death could be attributed to embolism of the pulmonary artery by a clot detached from a varicose vein.

Prof. Schützenberger, in reply, said that that was the only admissible explanation. A clot can travel from the thigh to the right side of the heart in a few seconds. He recalled a precisely similar case, in which Koeberlé made the autopsy and found a clot in the pulmonary artery. He had himself seen two brothers with large varicose veins, both of whom suffered from phlebitis, and both died suddenly and almost instantaneously, with symptoms of suffocation. The Professor believes that many of the cases of sudden death during the puerperal period are due to embolism.—*Lyon Médicale*, June 18th.

Injections of Chloral in Hydrophobia.—M. Prévost reported the following case at the séance of the Société de Biologie, on June 3d. A woman was bitten by a rabid cat in the month of July, 1875. The wound was cauterized with ammonia, but no other treatment was adopted. The patient became very melancholy, and was pursued by a presentiment that she was about to become mad, but her general health continued good, and the wound healed rapidly. Six weeks after the injury she began to suffer again from pains at the seat of the injury, and suppuration set in. She became nervous and irritable, and the presentiments were redoubled, and a few days later she was seized with a perfectly characterized attack of rabies. The paroxysms were extremely violent and very numerous. Hypodermic injections of morphine and inhalations of chloroform were tried, but failed to quiet the patient. Injections of chloral into the dorsalis pedis vein were then tried; one drachm was injected the first time, and the injections were repeated several times in twenty-four hours. These quieted the patient and produced a pretty calm sleep, but she gradually became weaker and died, without, however, having any more paroxysms. At the autopsy only the cord could be examined, and it was found to be healthy.

M. Hanot stated that he had used this treatment in a case of hydrophobia in 1874, and his patient was quieted for twenty-four hours.—*Gazette Hebdom. de Méd. et de Chir.*, June 9th.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

THE RESTRAINT SYSTEM IN THE TREATMENT OF OUR INSANE.

THE recent articles in the London *Lancet*, by Dr. Bucknill, on the American asylums for the insane, has infused a fresh interest in the management of these institutions, and has invited the criticism of our English brethren regarding our methods of treatment. The *Lancet* has taken occasion, in a general discussion of the subject, to speak very pointedly against the restraint system, as employed in our asylums. We are not surprised to find that this is done in a becoming spirit, and with a view of "promoting the interest of the insane, and the credit of medicine as a science in the United States."

Although much has been said on both sides of the question, the gratifying experiences in Great Britain and other countries give the best side of the argument to the non-restraint system. From the time of Pinel and Esquirol to the present, there has been a growing sentiment in the profession that the less we have to do with the strait-jacket the nearer will we approach the rational and scientific treatment of the lunatic. In fact, the real improvement in the treatment of the insane has been proportioned to the degree with which humanity has been infused into it. As a matter of principle, the non-restraint system is eminently correct, and should be considered a primary factor for good in all our estimates of success in treatment. It is true that very serious accidents frequently occur, and that sometimes valuable lives are sacrificed as a consequence of allowing too much freedom to insane patients; but if these occurrences are to be used as arguments in support of the restraint system, we have not progressed much farther than we were two hundred years ago. Rather should we endeavor, by a more thorough study of the rational history of insanity, to obviate entirely the necessity for even occasional restraint in the most innocent lunatics, than from ignorance or convenience submit patients to a method of treatment which not only does not cure, but in the vast majority of cases does harm. So long as it is the ambition of alienists to be considered scientific physicians, and not mere jailors, this idea will be kept in view, and all the hindering circumstances to its fulfilment will be patiently and strenuously combated.

That the American asylums have the unenviable reputation of habitually resorting to restraints is, we are convinced, in no small degree due to their systems of management. In the majority of the American institutions in which restraint is practised, it is almost impossible to test in a thoroughly practical manner the opposite system. The reason for this is, that too much is expected of the medical superintendent. He is required not only to be eminent in his specialty, but to such a professional qualification must be attached the attainments of architect, general manager, corresponding clerk, chief commissary, farmer, and landscape gardener. In the exercise of these multifarious duties it is impossible for him to give that medical care to the inmates of his institution which his position as chief medical director would seem to warrant. As a consequence, much of the details of management are left to medical assistants and nurses; and the assertion of the *Lancet*, that "the American system is in a large measure an habitual use of restraints to save trouble, or as some of the more candid superintendents put it, to avoid risks," is not altogether without foundation in fact.

In the present light of experience in the treatment of the insane, this is possibly the best excuse we have to offer for a persistent adherence to a reprehensible practice; and the sooner we remove the obstacles to its overthrow, the better for the reputation of our asylums and of the distinguished gentlemen who have them in charge. The superintendents themselves are gentlemen whose knowledge of their specialty is equal to any of their class in the civilized world, and their sense of humanity is such as to place them above even the suspicion of cruel practices; still, the circumstances of management by which they are surrounded, lay them open to a criticism to which as individuals they are hardly responsible. We repeat, then, that the reform in the treatment of our insane must begin in the reform in our methods of administrating the affairs of our asylums. It is useless to deny that there have been many examples of atrocious cruelty in the treatment of insane patients in American asylums by their attendants, and that these are directly due to the more or less prevalent system of applying strait-jackets and other instruments of restraint. The counter-charge that patients in English asylums are more subject to accidents and more given to homicides, etc., by a neglect of such restraint, than similar patients in our own asylums, is, even if true, a poor argument in support of a

practice which not unfrequently makes absolute cruelty one of its conditions. Although confessing to a national pride in the success of our institutions, we must acknowledge that we are behind our English cousins in the management of the insane, and that the *Lancet*, in advocating the claims of the non-restraint system, leads popular professional sentiment.

In regard to the uselessness of restraint for the purpose to which it is applied, that journal says:—

"We might ask the alienists of America to answer this question frankly for themselves. Is the condition of the patients in their asylums satisfactory as regards their immunity from accidents? Does the use of restraint prevent misadventure? Have there been no homicides, no cases of patients dying unattended in their beds, no broken bones, no bruises? If the system pursued were successful in the United States, the experience of alienists there would be directly opposed to that of our own superintendents. Dr. Conolly, in the reports just quoted, assigns as his primary reason for abolishing the use of restraints at Hanwell, 'the apparent inefficiency of mechanical restraint as a means of preventing accidents and mischief.' He distinctly alleges, and the observations of superintendents on this side the water strengthen the conviction, that coercion increases the excitement, and aggravates the very propensity to violence it is meant to check. It does more, and this is our third consideration,—its use is fatal to the benefit of the insane. Dr. Conolly says: 'One cherished error of the advocates of restraint is, that *it can at least do no harm to the incurable*. The fact is, that *no patients are more permanently injured by it, in temper, feelings, and habits.* So far from preventing violence, it provokes resistance. The patient is annoyed, irritated, and the propensity to do mischief is strengthened. Patients permitted to walk while in restraint were still capable of inflicting injury upon others; they were not protected from causes of irritation, or from the attacks of other patients.' Restraint does not prevent suicide, homicide, bodily injury, or death; it of necessity increases the irritation of the patient suffering it, and it inevitably engenders dirty habits. It is not a curative expedient; it is simply and solely a device to save trouble, or, if any one prefers the phrase, 'to avoid risks,' which, as a matter of fact, are not even reduced, much less avoided, by the irrational practice adopted."

Reviews and Notices of Books.

Leçons sur les Kératites. Par F. Panas, Chirurgien de l'Hôpital Lariboisière, Professeur Agrégé à la Faculté de Médecine de Paris, etc. Paris: A. Delahaye et Cie. 1876.

This very readable little work consists, as its title indicates, of a series of lectures on the inflammations of the cornea, delivered by M. Panas in the Paris School of Medicine. The first four of the sixteen lectures it contains are devoted to the consideration of the vascular and nervous supply of the eye, with especial reference to the cornea, and evince an amount of study and research that does great credit to the author, though there is perhaps but little that is entirely original in them. He lays stress on the facts that irritation of the cervical portion of the sympathetic on one side causes an increase in the intraocular tension on that side only, while irritation of the trigeminus on one side augments the tension in both eyes, and concludes from them that the fifth nerve is the medium through which sympathetic ophthalmia is produced. Division of the fifth nerve at or in front of the Gasserian ganglion leads to softening and destruction of the cornea, with apparently all the signs of the most violent inflammation; but it is remarkable that the process is not attended either by pain or increased heat. These effects are not produced when the nerve is divided behind the ganglion, from which the author concludes that the ganglion exerts a special influence on the circulation and nutrition of the eye. It is rather confusing in this connection, however, to find it stated in another place that the action of the trigeminus on the circulation of the eye is exercised through the medium of the sympathetic, and in still another that the fifth nerve is the trophic nerve *par excellence* of the eye, either directly or by means of some fibres that join it from the sympathetic. These three statements seem to be in direct contradiction.

In the fifth lecture he speaks of the influence of certain diseases on the circulation of the eye, and cites some interesting cases of tabes dorsalis and local asphyxia of the extremities with which ocular disturbances were connected. The sixth lecture is devoted principally to the consideration of the influence of the cornea on the aqueous humor. The author agrees with Lebert that it does not take part either in the secretion or the absorption of that fluid, and that as long as the membrane of Descemet remains intact, it offers an insuperable obstacle to its escape. Each individual endothelial cell, however, protects only that portion of the cornea which it covers, and if any one or more of them be removed the aqueous humor will filter through at that point and appear as a small drop of fluid at a corresponding point on the free surface.

The next three lectures are devoted to a general consideration of the therapeutic measures that are to be employed in the different varieties of ophthalmia. He considers the use of strong solutions of atropine as a collyrium reprehensible, for it has not only excited conjunctivitis, but in some cases even symptoms of general poisoning, that yielded, however, to hypodermics of morphine. Atropine diminishes the intraocular pressure by increasing the tonicity of the vessels, and consequently diminishing the secretion of fluids. It diminishes also the plasticity of the aqueous humor. The midriasis is due to a paralysis of the sphincter iridis and of the ciliary muscle, an effect which is produced independently of the circulation, as is shown by the fact of its production after the eye is enucleated. M. Panas recommends very highly the hypodermic use of morphine, which not only relieves the pain better than atropine, but also exerts a sedative influence on the inflammation. He often employs pure laudanum in water and glycerine as a collyrium in preference to giving opium by the mouth. He has derived but little benefit from blisters in his practice; but in some cases has got good results from parenchymatous injections of caustic substances, such as nitrate of silver, in the temple or neck. The local application of ice he considers to be dangerous, as in debilitated persons it is apt to excite sloughing of the cornea. On the other hand, he recommends hot fomentations for several conditions of the eye.

In the five closing lectures of the course the author gives excellent descriptions of the varieties of inflammatory affections to which the cornea is subject. Phlyctenulæ are deposits of round cells beneath the conjunctival epithelium, or between the epithelium of

the cornea and Bowman's membrane, or finally in the tissue of the cornea surrounding the nerves with which they pierce Bowman's membrane. In this last case the nerves are finally destroyed, and when ulcers form they extend through Bowman's membrane. This pressure on the nerves explains the intense photophobia excited by corneal phlyctenulæ. In some cases vegetations may take the place of the primitive phlyctenulæ, a condition that is illustrated by an excellent woodcut borrowed from C. Reymond. In this cut the leucocytes are seen to be partly replaced by newly-formed connective tissue, situated between the epithelium and Bowman's membrane, and elevating the former. The corneal corpuscles and Bowman's membrane are not implicated in the inflammatory process, and have apparently undergone no change at all. The diagnostic points between vesicular and phlyctenular keratitis are clearly laid down. Horner collected the reports of thirty-one cases of vesicular keratitis, of which twenty-eight were accompanied by herpes of the lips and nose. In the treatment of this form of keratitis, atropine, hypodermics of morphine, and closing the eye have been found useful; but the most satisfactory results have been obtained from the use of constant currents of electricity. When speaking of pannus the author cites a case of Chisholm's cured, after all other means had failed, by the use of a collyrium consisting of one part essence of turpentine and two parts olive oil.

M. Panas believes that the diffuse interstitial keratitis is of scrofulous origin, attacking, however, not those who have suffered during childhood from glandular scrofula, or the ordinary forms of strumous ophthalmia, but those who have been affected with eczema, impetigo, nodes on the limbs, ulcerous sore-throat, etc. It is most common about the age of puberty, and the patients generally show signs of arrest of development, especially in the teeth, which are often rudimentary, the cutting edges of the incisors presenting the peculiar notching to which Hutchinson has called attention. He combats here Hutchinson's assertion that this form of keratitis and the notched teeth are due to hereditary syphilis. It is not likely that syphilitic manifestations would be delayed so long, and, moreover, the treatment that has proved most successful has been anti-scrofulous and not anti-syphilitic. The almost complete immunity of the cornea from disease in cases of acquired syphilis is also a strong argument against Hutchinson's theory.

The last chapter is devoted to gonorrhœal or serous iritis, and is one of the most interesting and valuable in the book. During a service of two years at the *Hôpital de Lourcine* the author saw but one case of gonorrhœa complicated by rheumatism and iritis, an excellent illustration of the great rarity of the complication in women. It is remarkable that these accidents have only occurred in women in whom the urethra was the seat of gonorrhœa, and never when the vagina or vulva alone was affected. In men it occurs especially when the gonorrhœa is acute and involves the deeper portion of the urethra, and after the prostate, bladder, and testicle are already affected. The author's theory as to the mode of its production is that the lesions of the deep urethra and bladder react on the kidney and diminish the excretion of urea and uric acid, and that the accumulation of these substances in the blood leads to inflammation of the serous membranes and of the cornea and iris. In conclusion, we will only add that the book is well got up, and written in an easy and attractive style. Though offering to the profession but little that is new or original, it bears evidence of careful study, and contains much that must be instructive both to specialists and to the profession at large.

Lectures on Orthopedic Surgery and Diseases of Joints, delivered at Bellevue Hospital Medical College during the Winter Session of 1874–1875. by Lewis A. Sayre, M.D., Professor of Orthopedic Surgery, etc., etc., etc.—New York: D. Appleton & Co., 1876, pp. 476.

In his introduction to this work, which has been long waited for and is received gladly, Prof. Sayre gives us to understand that the lectures are printed just as they were delivered, the services of a stenographer having been employed to insure accuracy and save time. Whether this is meant to challenge our admiration, forestall our criticisms, or awaken our sympathy for the overworked author, we are not told; nor would it matter much, were it not accompanied by some other statements that are more legitimate subjects of criticism. Prof. Sayre adds that they were delivered without preparation, and many of them upon cases just presented to him for the first time in the lecture room. We may be permitted to doubt if this is just what his friends had in mind when they urged him to publish his peculiar views, and we can only be thankful for the unexpected excellence of the result, the completeness of which, however, is due to the care taken to supply from private records the deficiencies of chance clinical material.

Ordinary clinical lectures are either a regular didactic course, illustrated by cases, or are discourses upon some patient as a text, in which the etiology, pathology, diagnosis, and treatment of the diseases involved are discussed. Dr. Sayre has happily combined the two, and has embraced in his twenty-nine lectures not only all or nearly all the diseases we should have expected, but also a few others whose presence is authorized only by the rather extensive meaning which the author gives to the term orthopedic. The plan of the book is the one best adapted to give the reader all the benefit that can be obtained from the author's very extensive experience, clear apprehension of the ends to be obtained, and of the mechanical and operative measures calculated to secure them. Systematic treatises may be left to those whose reading is more extensive and whose clinical experience is less, to professors of theory and practice rather than to those of clinical surgery. Although the pathology and physiology leave something to be desired, as witness the ignoring of the action of the peroneus longus in maintaining the arch of the foot, the explanation of the pain in talipes valgus, which is purely hypothetical, and indeed opposed to the only actual data which we have upon the subject as contained in the report made to the Académie de Médecine, by Prof. Gosselin, of an autopsy rendered possible by death from an intercurrent cause, and the pathology of genu valgum, which is dismissed with a word as if it were not still the subject of much controversy; still these are points of minor importance to the general practitioner so long as the hypotheses involved are considered only as "working" ones, and are calculated to fix the outlines of treatment in the mind of the reader. The treatment itself is described with such detail, and with so much attention to the principles governing it, that if, to adopt a statement of Carlyle's, the population of this country was not "forty millions of people mostly fools," the publication of this book ought to be sufficient to banish club-foot forever from among us, and many a charitable society might employ its funds very usefully in preparing and distributing a tract made up from the lectures on talipes.

The first six lectures are introductory, devoted to general considerations, definitions (we may mention in passing that the etymology of orthopedy is not the one generally accepted), deformities, and principles of treatment. Talipes is treated of in the five following, and cases are given of most of the varieties. The brilliantly successful treatment of the cases of talipes valgus in Lecture VIII. makes us regret that Dr. Sayre has not encountered or described the other variety, talipes valgus, but with the arch of the foot preserved, due likewise to excessive use of the limbs, generally in adolescents. That is a variety which cannot be attributed solely to weakness of the tibialis anticus, and in which, the arch of the foot being preserved, would probably not need artificial support. The etiology of this affection has been the subject of much controversy and has generally been placed in the paralysis of some or the excessive contraction of other muscles; and it is only within the last ten years that attention has been called, principally by Gosselin (Bull. de l' Acad. de Médecine, 1865, and Clinique Chirurgicale, 1873), to the fact that the initial symptom is pain in the medio-tarsal articulation, and that probably therefore the immediate cause is an arthritis manifesting itself subsequently by reflex contractions similar to those which are the constant accompaniments of other arthrites. The apparent wasting of the tibialis anticus, and the actual diminution in the size of the leg, which are most striking facts in Dr. Sayre's cases of flat-footed painful valgus, might be due, the first to the extension of the muscle when the foot is everted, and the second to the insufficient use of the limb. And in fact, in the description of the case given upon pages 68 and 69, there is nothing to indicate that the muscles were at fault; the only lesion shown is an arthritis, the pain of which is relieved by partial or entire immobilization of the joint in a suitable position.

Twelve lectures are then given to diseases of the joints, two to diseases and deformities of the spine, and two to anchylosis. The lack of space will not allow us to discuss them in detail. Suffice it to say that the treatment of the subjects is marked by the same vigor of style, clearness of conception, and definiteness in the object sought and means taken to attain it, that have been already mentioned.

The publishers have done their work handsomely. The paper is stout, the type large and clear, the illustrations all that could be expected, and as a rule are well chosen and likely to be useful.

Consumption in Australia. By C. E. Reeves, B.A., M.D., Author of "Heart Diseases and Aneurism in Australia;" Editor of "The Medical Record of Australia," etc., etc. J. Brooks, 232 Bourke street, East Melbourne. 1874.

Dr. Reeves has divided his monograph into ten chapters. In the first he mentions the rarity of tubercular deposit in the lungs in that country, and studies how cavities are usually formed. According to the author's observations, tubercular deposit in the lungs is the exception in Australia, although consumption is of frequent occurrence. As he has seen the disease, it has almost invariably been of inflammatory origin, and in some of the cases reported, the rapidity with which it has passed through the stages of what he calls congestion, induration, and softening, and the formation of cavities, is astonishing. For, the doctor states, pulmonary cavities may form in from ten to fourteen days in patients who are somewhat broken down and have a tendency to lung disease. Dr. Reeves speaks of congestion, as an easily recognized condition, and one from which a cavity may be formed by the breaking down of the *clot which occurs in this stage.* This certainly is quite at variance with what is commonly understood by the term congestion as used in this country. The proposed plan of treatment for the congestive state is confinement in bed in a dry room, blisters, salines with acids, beef-tea and wine freely. The doctor claims that such treatment, as a rule, aborts the attack and saves the life of the patient. In general, the conclusions arrived at in Dr. Reeves' book are interesting, chiefly because of their wide variance from what we have been led to believe occurs in similar cases in this country. For example, mention is made of congestion of the ultimate air-cells, unattended with congestion of the substance of the lungs; a fine crepitation or wheeze, said to be characteristic of congestion; that congestion may never pass into induration (Dr. Reeves' second stage) but into a cavity because of a clot being effused into the congested lung; and a peculiar nomenclature is exemplified under the term "mucous wheeze" excited in the ultimate air-cells. In the second chapter Dr. Reeves considers the influence of the seasons in producing diseases of the lungs. He reports that the coldness of the season has less to do with exciting them than the very sudden changes, perhaps from 117° or 120° F. to 50° or 60° F., with a change of the wind, accompanied with cold rains. It is also stated that lung diseases occur with greatest frequency in the hot months (December, January, and February), and that apoplexy and bleeding from the lungs are very liable to occur if the heat continues beyond the usual three days without change. In Melbourne and vicinity large quantities of water have been used for irrigating the land, and the effect has been to greatly increase the amount of moisture in the atmosphere. That increase, Dr. Reeves reports, has been attended by an increase of lung diseases, especially asthma, and has rendered the town a bad residence for consumptives. In chapter three, an analysis of 205 cases of consumption is given, and it is found that only in 72 was there a tubercular tendency. In the remaining 165 cases, exposure to cold, colonial fever (described as a low form of fever, with lung disease), and diseases of the heart were the most frequent causes. In chapters four, five, six, seven, eight, and nine, the author reports his observations upon consumption as produced by pulmonary apoplexy; by inflammatory processes; by acute and chronic gangrene; by chronic induration and tubercles; by bronchitis, pulmonary emphysema, and asthma, and by hydatids in the lungs.

It is reported that in no country, except Iceland, is hydatid disease so common as in these colonies, and that prior to 1861 it was scarcely known in the hospital. It was, however, very common at the sheep stations up in the country; and there it was produced partly by eating raw or partially cooked mutton, and drinking unboiled water from water-holes frequented by sheep, dogs, and other animals. Eating the common water-cress is also attended with danger when taken from waters frequented by these animals, and sometimes the cysts can be seen attached to the plants growing in the pools and ponds. The upper and middle lobes of the lungs are said to be more frequently affected, but the right lower lobe is especially liable to become implicated when the hydatid cyst is seated at the upper part of the liver. The tenth chapter is made up of brief references to cancer of the lung, worms in the lung (unsatisfactory note), and what the author calls bronchial polypi, or formation of membranes in the bronchial tubes, of which he has seen

three cases. In all these cases the disease was chronic, and in no case has he seen acute membranous formation in the bronchial tubes occurring in the colony, except in connection with croup. As already stated, this book is interesting because it contains a report of facts and observations made in a comparatively new field for study, and the report bears the impress of accuracy.

Correspondence.

MEDICAL MATTERS IN PARIS.

To the Editor of The Medical Record.

THE SOUFFLE OF PREGNANCY—THE INTRAVENOUS INJECTION OF CHLORAL—PRACTISING FOREIGNERS—HOTEL PHYSICIANS.

Sir:—Supposing that some account of things medical in Paris, from one actually *en rapport* with them, might not be uninteresting, I send you a few notes to-day respecting such things as seem most important at present.

The Academy of Medicine has been engaged for some time past in discussing the nature and origin of the *souffle* which is heard during pregnancy. A young physician by the name of Glénard undertook to demonstrate practically that this *souffle*, so far from being placental or uterine, has its seat in the epigastric arteries; but, under the sharp criticisms of his confrères, he made an inglorious failure and actually abandoned his theory for another—which he was equally unsuccessful in maintaining. The subject was then taken up by Bouillaud, whose elaborate researches upon vascular and cardial sounds have rendered him a recognized authority throughout the medical world, and discussed at considerable length and with much ability. According to him all vascular sounds are of two varieties, viz.: *normal* and *abnormal*. *Normal sounds* are scarcely distinguishable when arteries are subjected to no mechanical compression; and yet, careful observation detects, even under normal conditions, two muffled sounds which correspond to the dilatation and contraction of the vessels. If the slightest compression be made so as to diminish the capacity of the vessel, the friction of the blood at the point compressed immediately develops a blowing sound—*un bruit de souffle*—which can be readily distinguished, although no change has taken place in the chemical and physical character of that fluid. *Abnormal sounds* are produced under a variety of circumstances, and result from some structural alteration in the heart or the arteries, or from some modification of the fluid which it is their function to distribute. The souffle of the vessels, which has been designated according to its character the *bellows sound*, the *cooing note*, the *arterial murmur*, *le bruit du diable*, etc., and is a type of this variety of sounds, can always be intensified by an amount of pressure sufficiently great to increase the friction of the blood current against the contiguous parietes. The souffle of chloris and anæmia is due to a diminution in the density of the blood, which can be measured accurately by the *Acrometre de Bouma*, and it subsides as that fluid approaches its normal condition.

The study of these phenomena has led him to the conviction that the *souffle of pregnancy* has its seat in vessels of a certain calibre and contiguous position, which are compressed as the womb develops. The fact that this sound is isochronous with the movement of the heart of the mother and not of the child, shows that it is not developed in the placenta; while the circumstance that it is heard in connection with abdominal tumors—such as ovarian cysts—when pregnancy does not exist, is equally fatal to the theory of its uterine origin. By this argument of exclusion, as well as the additional *facts*, as he states them, of a cessation of the sound when the patient is so placed as to relieve the pressure upon the principal vessels of the pelvis, and of its increase upon one side or the other, as the uterus is made to fall in that direction, he arrives at the theory that the *souffle of pregnancy* has its seat in the *iliac arteries*.

At the next session of the Academy, Professor Depaul took the floor and entered into an elaborate argument against the views promulgated by Bouillaud. He began by admitting that his adversary was partly right in his deductions, but claimed that the explanation given by him did not cover the whole ground, and was defective in the most essential particulars. There is, he contends, a sound which has its seat in the *iliac arteries*, but it is not the true *souffle of pregnancy*. This sound, like all the *bruits* emanating from compressed arteries, is invariably *accompanied by pulsation*, while the *souffle of pregnancy has no such accompaniment*. These two soufflés, the one accompanied by pulsation and the other not accompanied by pulsation, can sometimes be heard contemporaneously, but they are essentially different from each other. Besides, the *souffle of pregnancy* is heard before any compression of the artery has taken place, and it does *not* disappear or abate when the position of the womb is changed. He denies emphatically that the *true* souffle can be heard in connection with ovarian cysts, etc., and asserts that the sound thus developed is always accompanied by pulsation. To his mind the demonstrable facts that the *bruits* of the impregnated womb are superficial, and that they can be heard over the whole area of the abdominal walls, furnish likewise very strong arguments against the position taken by Bouillaud. He thinks that the *souffle of pregnancy* depends for its production upon the peculiar anatomical conditions which this special state develops in the organ concerned in the work of reproduction, and that the phenomenon is exclusively uterine in its origin and connections, *i. e.*: is due to the mode in which the blood circulates through the parietes of the hypertrophied womb. As a means of still further sustaining this theory, he presented an apparatus which has been so constructed as to reproduce the precise anatomical circumstances upon which the *souffle of pregnancy* depends for its production. This apparatus consists in an india-rubber tube, having nearly identical dimensions with the crural artery, to which is attached a pouch capable of acting both as a drawing and as a forcing pump. During the action of the pump no sound can be detected in the tube *except when it has been compressed* at some particular point, while the souffle so developed is *invariably accompanied by pulsation*, just as in the iliac hypothesis of Bouillaud. By adjusting to the extremity of the first tube two other tubes having double its calibre and reuniting with each other subsequently, the conditions of the circulation in the uterine parietes can be fairly realized. Then, having set the pump in motion, and applied a stethoscope upon a level in the bifurcation of the tubes, a *souffle*, unaccompanied by shock, movement or pulsation, and exactly resembling that of pregnancy, can be distinctly heard. This experiment the Professor deemed *conclusive* as to the incorrectness of Bouillaud's theory and to the absolute reliability of his own, although he expressed a hope

that his *confrères* in the department of obstetrical surgery would seize upon the occasion of a Cæsarean section to auscultate the womb itself, for the purpose of subjecting the views presented by him to an *experimentum crucis*. There is great diversity of opinion here, not only in regard to the subject itself, but with reference to the advantage obtained by the respective disputants. It is generally admitted, however, that these distinguished academicians have fully sustained their well-earned reputations, and added another honorable page to the history of their illustrious and useful careers. Should the debate be continued, I shall keep you duly informed respecting its progress and result.

Anæsthesia by the intravenous injection of chloral is attracting some attention. In a paper recently addressed to the Academy of Sciences, M. Oré describes an operation performed by him, in which insensibility was induced in this way very readily and without injury to the patient. The case was that of a workman in a steam-engine factory, aged sixteen years, who, on the 4th of October last, injured his right leg about two inches below the knee, by striking it against a bar of iron. About the beginning of November the whole leg became greatly swollen, while acute and persistent pain developed itself and a well-defined tumor invaded the entire circumference of the limb. Amputation became inevitable, and it was performed by M. Laland—a solution of chloral in water having been injected into a vein contiguous to the seat of injury. Previous to the injection the patient manifested great anxiety and nervous excitement; but as soon as four *grms.* of the chloral solution had been introduced, he became perfectly tranquil, and when the quantity injected reached 6¾ *grms.* he was found to be thoroughly anæsthetic. The pulse remained at one hundred and eight and the breathing at thirty-two during the operation, whilst no reflex actions were developed. After having slept quietly for two hours, he opened his eyes, talked coherently, and then lapsed into a placid slumber which lasted for five hours. He then made a rapid recovery, and is now in perfect health. M. Sinhart, an Austrian surgeon, has also reported a case in which this method of inducing anæsthesia was successfully attempted. A young man having sustained a dislocation of the shoulder, and all efforts at reduction proving abortive, one hundred and five grains of chloral in solution were slowly thrown into a vein upon the left arm, with the result of securing complete insensibility at once. Reduction was then readily affected, and the patient, after sleeping quietly for several hours, awoke refreshed and comfortable. Chloroform was not employed, because of an idiosyncrasy which forbade it.

Although no action has been taken in regard to these cases, and it is understood that Parisian surgeons regard this plan of inducing anæsthesia as both dangerous and unnecessary, I feel confident of its value under certain exceptional circumstances.

When the ordinary anæsthetics cannot be borne, or fail to produce their effects—as occasionally occurs—or in uncontrollable cases of eclampsia, tetanus, hydrophobia, mania, and other similar morbid conditions, this additional resource of the medical art may prove a godsend, if judiciously employed.

A desperate effort is being made to prevent foreigners from practising medicine and surgery in France. Under the plea that German physicians are "squatting" upon the sacred soil of the Republic and persuading patients to test the merits of the spas of "Vaterland," it is sought to enact a new law in regard to the *authorization* of strangers, which will be almost prohibitory in its efforts. Heretofore the prerogative of according these *licenses* has appertained both to the minister of public instruction and to the medical faculty of the University, with or without an examination, according to their discretion. Should the proposition of M. Roger-Marvais be approved by the legislative body, the minister will only be left the right to dispense with attendance upon the courses of lectures required ordinarily; while the faculty will be empowered to subject each applicant to a searching examination and to grant an *authorization* or not, as it thinks proper—the penalty for assuming the title of doctor or surgeon, unless so authorized, being a fine of a thousand francs and an imprisonment of not more than six months. Under the existing system an alien has found it exceedingly difficult to secure the requisite protection because of the opposition of the faculty, and if the obstacles be further augmented by placing the whole matter virtually in the hands of that body, and of exacting a critical examination in a strange language, it will be next to impossible for another foreign physician to settle in France. Of course, the new law will not interfere with those of us who have been duly authorized under the provisions of the old one, and the tempting prize of the American *clientèle* cannot be secured until we have "gone the way of all flesh" and left the field clear to our native confrères.

Apropos of this subject I am reminded of a custom prevailing abroad against which a word of warning is appropriate. Nearly every hotel in Europe has its regular corps of doctors, who not infrequently pay for the privilege by dividing receipts with landlords, concierges and garçons. As a part of the general system of spoliation to which travelers are everywhere subjected, no effort is spared by the interested parties to *force* these individuals upon every unfortunate guest who happens to be an invalid, or even to look like one. But few of the *médecins titulaires*—as these hotel *arachnidæ* style themselves—have merit as physicians, whilst their fees are enormous and their professed ability to "speak English" is limited to the phrase in which they make the latent assertion. Unless a traveler is weary of existence and has an endless amount of money to distribute gratuitously, he should make it an invariable rule neither to consult a hotel proprietor or employé in regard to the choice of a physician, nor to submit to a prescription from any medical man introduced by such people. By applying at his *legation* or *consulate*, he can always obtain the addresses of really reliable physicians, both native and foreign, and learn into whose hands he can most safely intrust his life and his letter of credit. The better plan, however, is for him to obtain in advance from his family physician a list of such medical men in the principal cities of Europe, as he can consult with the greatest advantage.

I have just had the pleasure of meeting in Paris two members of the profession of New York, who are indeed an honor to it, and whose high character and splendid abilities are as thoroughly recognized here as they are at home. Dr. Fordyce Barker is now seeking repose and recuperation in his annual tour of the continent; while Dr. J. G. Crane, after a delightful winter in the East, has recently sailed for America. For one, I wish them length of days and still increasing honors.

Hoping to find time to write to you again and at no distant day, I must say *au revoir*.

Yours very truly and respectfully,

EDWARD WARREN, M.D.

MEDICAL CENTENNIAL AFFAIRS.

MECHANICO-THERAPEUTIC INSTITUTION OF STOCKHOLM —STEAM SUBSTITUTED FOR MUSCULAR POWER—THE VARIETY OF MACHINES FOR PASSIVE AND ACTIVE MOVEMENTS — THE CASES TO WHICH THE TREATMENT IS APPLICABLE—THE MEDICAL, SURGICAL AND THERAPEUTICAL EXHIBITS OF THE UNITED STATES—NORWEGIAN COD-LIVER OIL.

(From our Special Correspondent.)

PHILADELPHIA, Aug. 19, 1876.

AFTER leaving the Government Building, the interesting exhibits of which have been referred to in previous letters, so far as they specially attract the attention of the medical profession, we may next direct our footsteps towards the Main Building. This is the great centre for vast displays of marvels of science and skill, in several of the departments of which the medical man is legitimately interested. On our way to it, however, we pass, by a right-angled course, directly in front of the Machinery Building, the incessant clatter of which induces us to take a glance at the interior. We make but a brief visit, as the exploration of the immense aggregation of mechanical labor in motion will occupy us more fully on another occasion. Possibly the time of our visit is between four and five o'clock in the afternoon, at which hour only is exhibited in the Swedish department (Section F 2) the practical working of the Mechanico-Therapeutic Institution of Stockholm. The apparatus is placed along the extreme northern wall of the building, not far from the entrance. To the casual observer it is a rather odd-looking collection of mechanical appliances. On inquiry, however, we learn that its objects are the preservation and restoration of health through systematic exercise of the muscles, and through various mechanical operations on the body. The institution was established in 1865 by Dr. G. Zander, who was recently in Philadelphia.

In ordinary gymnastic health institutes, the patient is treated by an operator or gymnast, who makes both active and passive movements, as they are called, according as the patient himself is active or passive. Dr. Zander, however, substitutes machinery worked by steam for the muscular power otherwise required, which has the advantage of facility of steady regulation and of graduated increase of the force to be employed. The machines constructed are adapted to be worked by most of the various sets of muscles. The apparatus of the institution consists of sixty-seven different machines, although only twelve of these are placed in the Swedish department for exhibition. With these sixty-seven forms of apparatus, forty-six movements are practicable. Seventeen of the machines are for active arm movements, eighteen for active leg movements, nine for active trunk movements, and twenty-three for passive movements. The latter are effected by a steam engine of five horse-power, and include rubbing, shaking, etc., while the patient is in repose. With these machines are accomplished twelve distinct movements of flexion, extension, adduction, abduction, etc., of arms, hands and fingers; fourteen similar movements of the legs and feet at the different joints; flexion, extension and twisting of the trunk in lying, sitting and standing positions, eight movements; and twelve movements of shaking, chopping or hammering, tapping, kneading, rubbing, rolling and swinging, performed by the operator. Ladies and gentlemen patronize the institution, not only as patients, but for the purpose of normally developing their muscular systems. Every one receives a prescription enumerating the movements to be performed, twelve of which are generally accomplished daily, the movements being changed, wholly or partially, after the twelfth day. This methodical treatment is said to be beneficial in chronic cardiac cases, and is also employed with advantage in constipation, diseases of the joints, rheumatism, spinal curvature, etc., etc. The shaking movement is especially commended by Dr. Zander for its salutary effect on organs in the vicinity of the region thus agitated; tired muscles seem to recover themselves to a great extent; pain is subdued; the walls of the bladder and rectum contract from the shaking of the sacral bone; shaking of the chest facilitates expectoration in catarrh; the same motion of the back relieves nervous palpitation, etc. These effects seem possible and plausible, and in the hands of a sensible operator, who is no mere enthusiast and understands when not to apply this powerful apparatus, are doubtless beneficial in many cases in which medication by drugs might be too slow in action or absolutely powerless for good.

Crossing now the open plaza which lies between Machinery Hall and the Main Building, we enter the portals of the latter, and must pass more than half its entire length before reaching the groups of exhibits in the United States Department, should we wish, as physicians, to commence our examination with that beautiful and extensive display. One might imagine that by the time a survey was made of the various classes of exhibits embraced in each country under the head of Medicine, Surgery and Prothesis, there would be but little left to interest the physician, looking at the subject from a merely medical aspect. Such, however, is very far from being the case. This trio of congenerous exhibits embraces: 1. Medicines; officinal (in any authoritative pharmacopœia), articles of the materia medica; preparations, unofficinal. 2. Dietetic preparations, as beef extract and other articles intended especially for the sick. 3. Pharmaceutical apparatus. 4. Instruments for physical diagnosis, clinical thermometers, stethoscopes, ophthalmoscopes, etc., except clinical microscopes, which are included in another class (optical and thermotic instruments and apparatus). 5. Surgical instruments and appliances, with dressings, apparatus for deformities, prothesis, obstetrical instruments. 6. Dental instruments and appliances. 7. Vehicles and appliances for the transportation of the sick and wounded, during peace and war, on shore or at sea. In addition to all these interesting subjects, we find scattered through the exhibits from all parts of the world many semi-medical or at least medico-popular items, such as mineral and other waters, chemicals, instruments of science and philosophy, matters relating to the physical and social condition of man, etc. Machinery and Agricultural Buildings also contain numerous exhibits that will challenge professional attention, the latter especially, such as are related to his aliments, solid and fluid.

It may be well to state, at the outset, that the whole magnificent and vast display in the Main Building is arranged under three general heads or departments: 1. Mining and Metallurgy. 2. Manufactures. 3. Education and Science. Under the second head are included not only the groups previously alluded to under the class of Medicine, Surgery, etc., but also chemicals and pharmaceutical preparations, which, as already stated, do not strictly belong to the class just mentioned. We do not propose, however, to follow this plan of division through the minutiæ of the whole exhibition. A much more interesting and instructive course will be to study each country collectively through all its

medical exhibits, rather than to take an arbitrary classification, and tediously trace it through country after country to the point of thorough exhaustion of the subject, and possibly of the reader also.

Beginning, therefore, our tour through the building at the main or western entrance, and momentarily passing Italy, which first confronts us and deserves a more extended notice than we can to-day give it, we arrive at Norway. The chemical display here is limited almost wholly to an exhibition of cod-liver oil by Peter Möller of Christiania, J. Borthen and C. Jordan of Trondhjem, Lauritz Devold and the Aalesunds Medicintran Co. The long tubes in Möller's exhibit, filled with oil, look like the pipes of a church organ. Borthen's oil is very light and transparent, and all of them are almost tempting enough in appearance for steady imbibition by the thirsty. Möller's and Jordan's seem to have secured the medals in previous exhibitions. The judges of this Congress will, of course, take copious draughts of each before awarding the palm for superiority. H. S. Ditten of Christiania, Court Apothecary and Proprietor of the State Hospital Dispensary at that place, exhibits "druggists' medicine chests for travelers," being small, cheaply made, unattractive, shallow tin boxes, such as children in this country use for slate pencils, sponges, etc., containing eight or ten minute vials, in which are remedies against colic, coughs, hemorrhages, etc., for all the emergencies and ills which travelers' flesh is heir to. The costive are also invited to help themselves to sample boxes of aperient pills manufactured behind his counter, but very few of the visitors seem willing to make so public a confession of their shortcomings. In the department of education and science, Drs. Danielsen, Physician-in-chief to the Elephantiasis Hospital at Bergen, and Prof. Boeck of Christiania, jointly contribute a treatise on the skin and another on elephantiasis; but otherwise, with the exception of a zoo-geographical map of Norway, containing a complete list of the vertebrate animals of the country, by Robert Collett, Assistant of the Zoological Museum at Christiania, there is nothing else on exhibition of exclusive interest to the medical profession. We might, indeed, except the governmental quarto volume, one of a general series of official documents on three heterogenous subjects—the sanitary condition of Norway, elephantiasis, and insane asylums. The treatise on elephantiasis, by the two gentlemen already referred to, was also published at the expense of the government.

R. J. D.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from August 20th to August 26th, 1876.

Alexander, C. T., Surgeon. Granted leave of absence for 20 days. S. O. 173, A. G. O., Aug. 22, '76.

White, C. B., Surgeon. Granted leave of absence for 20 days. S. O. 174, A. G. O., Aug. 23, '76.

Price, C. E., Asst. Surgeon. To continue on duty with 4th Artillery, at Cheyenne, Wyo. T. S. O. 115, Div. of the Pacific, Aug. 17, '76.

Hoff, A. H., Asst. Surgeon. Died at Germantown, Pa., on Aug. 19, '76.

Medical Items and News.

Contagious Diseases.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending August 26, 1876.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.

Newspaper Notoriety.—We have been somewhat surprised to witness the daily parade of the so-called opinions of respected gentlemen in our profession in connection with the condition of a distinguished financier in this city, upon whom they have been in attendance. Of course they are not accountable for anything that is said concerning their patient, for if they were we should be ashamed of them. It is unfortunate, however, that the newspaper reporters not only have the opportunities for manufacturing professional opinion, but the privilege of degrading the position of a medical attendant to that of a hired nurse. Altogether the profession has in no manner been elevated by the unfortunate notoriety which has been thrust upon the doings and sayings of the gentlemen to whom we refer. Again we say that we cannot believe that they are in any way accountable for the unprofessional aspect of their case, and consequently tender them our sympathy.

The Model City of Health, proposed by Dr. Richardson, of London, is about to be tried practically. A site has been secured on the coast of Sussex, England, where the city will be laid out.

Flea Bites and Phlebitis.—An undertaker, on examining the death certificate of a man who had died of phlebitis, the result of the sting of an insect, did not see why flea bites could not be spelled in the old-fashioned way. The same individual ridicules the Latin rendering of very coarse veins, and has become an earnest advocate for good preliminary education among physicians.

International Medical Congress.—The Royal Medical and Chirurgical Society of London has appointed as delegates Dr. Charles John Hare, F.R.C.P.; Dr. Robert Barnes, Lecturer on Midwifery, St. George's Hospital; and Mr. R. Brudenell Carter, Prof. of Surgery, Royal College of Surgeons.

Bellevue Hospital.—At the meeting of the Board of Commissioners of Public Charities and Correction, held August 9, 1876, Dr. John G. Curtis was appointed Visiting Surgeon, *vice* Doctor Henry B. Sands, resigned, and Dr. Thomas T. Sabine appointed Visiting Surgeon, *vice* Doctor Thomas M. Markoe, resigned.

Poisonous Mushrooms.—Prof. Schiff, of Florence, has demonstrated that the non-edible mushrooms have a common poison, muscarina, and that its effects are counteracted either by atropine or daturine. Italian apothecaries now keep these alkaloids in the rural districts where the consumption of the non-edible fungi is apt to occur.

Original Communications.

A REPORT OF SIX CASES OF MIDDLE EAR DISEASE, INDUCED BY THE USE OF THE NASAL DOUCHE IN TREATING NASO-PHARYNGEAL CATARRH.

By WM. SHAW BOWEN, M.D.,

OPHTHALMIC AND AURAL SURGEON TO THE HARTFORD HOSPITAL.

Since the Weber, or, as more commonly called, the Thudichum douche has been brought into use in this country as a means of treating catarrh of the nasal passages and of the pharynx, it has become a favorite of a large portion of the profession, and of the laity generally. In a climate especially predisposing to this affection, where a large proportion of the people are suffering to a greater or lesser extent from the oftentimes disgusting and annoying malady, any simple, efficacious, and apparently safe appliance, like the douche, is certain of appreciation, and inspires general confidence; and this confidence is increased when eminent scientific authority pronounces in its favor. The difficulties attending a complete cure, and oftentimes any permanent modification of the affection, even by specialists, are so great that the charlatan finds an ever teeming field for practice in this direction. That the use of the Weber douche is one of the best methods of cleansing the nasal passages and superior portion of the pharynx there is no doubt; and simple solutions, as of chloride of sodium, and of permanganate of potassa, sometimes produce remarkably beneficial results when introduced to the Schneiderian membrane by this simple instrument, so easy of manipulation as to be used by a child, after a little instruction. Under different names, and accompanied by a host of patented nostrums known as "Catarrh Cures," it is found in every apothecary's store, and is more generally used than any other means of treating what may be properly termed the national disease. Of late, however, the attention of certain aural surgeons has been directed to occasional injurious effects produced on the Eustachian tubes and the tympanic cavities attending its use, and Prof. St. John Roosa, of New York, first called attention to cases of acute suppuration of the middle ear, undoubtedly produced by a current of fluid thrown by the douche into the Eustachian tubes and to the delicate parts beyond. Dr. Roosa's statement produced some discussion, and not a few scientific men doubted the conclusions and defended the instrument. Dr. Roosa finally published, in the *Archives of Ophthalmology and Otology*, a detailed report of sixteen cases occurring in his own, and in the practice of other reliable observers, which settled the question in the minds of otologists generally. Dr. Pardee, of New York, has published a report of cases of ear trouble directly traceable to the use of the douche; and recently Dr. Henry L Shaw, of the Massachusetts Eye and Ear Infirmary, has given his experience in eighteen cases, not all of them due, however, to the use of the douche, three being caused by the posterior nares syringe, a hitherto safely regarded instrument; and one case from snuffing salt and water from the hand through the nostrils.

The late Prof. Hinton, of London, mentions a case, in his *Questions of Aural Surgery*, in which the douche was used by "a most careful and competent physician." "The patient was a clergyman, aged seventy, and severe inflammation was set up in each ear. The liquid had a fall of five feet." He also observes that possibly the danger is greater in advanced age, owing to wasting of the tissues.

The writer has recorded six cases, occurring in his own practice, where there can be no doubt that the ear mischief was entirely due to the forcible entrance of fluids thrown by the douche to cleanse the nasal passages and pharynx. In five of the cases the pain and disturbance about the ear was observed immediately after the fluid was passed into the nostril, and in the remaining case the connection was so close as to justify a positive opinion as to the cause of the serious suppurative inflammation that followed.

The structure of the lining mucous membrane of the Eustachian tubes is such as to be antagonistic to the passage of fluids from the pharynx to the cavity of the tympanum. The ciliated epithelium moves downwards towards the pharyngeal openings, and as the walls of the tubes normally are in apposition in the greater portion of their length, except in connection with the act of swallowing, there is requisite a certain amount of force to inject a fluid to the cavities of the middle ear behind the drumhead. The action of the douche depends upon the physiological action of the muscles of the palate, which close the lower part of the pharynx, and prevent the passage downwards of the medicating liquid, which, entering the nostril on one side, filling the nasal cavity and upper part of the pharynx, escapes through the opposite nostril. If there is undue potency of the tubes, the current may be forced up against the cilia, and possibly reach the tympanic cavities, although inflammation may result without its going so far, but on account of the extension of tubal irritation. The more frequent source of danger, however, is the act of deglutition, which may occur while the pharynx above the palate is filled. The mouths of the Eustachian tubes simultaneously open, and the hydrostatic action occurs along their course. That this occurs frequently without any injurious results following I am convinced, but the danger always exists. Fluids thrown into the tympanum cavities may be retained until absorbed. According to Mr. Yule's experiments,* the resistance of the tubes is greater from above downwards, and "a warm alkaline solution thrown downwards through an imperforate drumhead required force sufficient to raise a column of mercury four inches." Whatever is forced upwards by pressure, probably remains in the great part until absorption takes place. The tendency of pus in the tympanic cavity to find its way outwards through the drumhead is well known, and in acute catarrh the inflammatory products are usually relieved in this way, instead of finding an exit through the Eustachian tubes into the pharynx. When the current of medicated fluid from the douche is passing through the nostril into the pharynx, the act of deglutition is to be strenuously avoided, and this precaution is insisted upon by the advocates of the douche as a means of treating catarrh, it being asserted that with proper care the mishap is impossible. Notwithstanding the utmost attention, occasionally a portion of the fluid may escape into the throat below the palate, and swallowing involuntarily takes place. Of course, the risk of entrance of some of the solution into the open orifice of the tubes is very great, and upon the distance penetrated depends the risk of resulting ear disturbance. When this risk is fully considered, and with the grave consequences of suppurative inflammation in view, it is certainly true

* "Journal of Anatomy and Physiology," November, 1873.

that the suggestions already made by observers in the field of otology are of the utmost importance; and that the apparently simple and useful nasal douche is really a dangerous instrument, the use of which should be discarded, except under conditional circumstances. Careful observers, physicians in large general practice, have stated that there has been within a few years an increased number of cases of "running from the ear," and of ear-ache, in adults, and I have no doubt that, if reliable statistics could be collected, it would be demonstrated that the use of the nasal douche has actually increased the proportion of ear disease to an appreciable extent.

It would be exceedingly difficult to demonstrate that chronic otitis media, with general sclerosis of the parts, one of the most formidable of all aural diseases, may be excited in the same way, yet I believe that such is the case, and that irritation of the tubes may ultimately extend, and finally terminate in this affection. Dr. Shaw, of Boston, takes this view, and it is certainly rational and scientific. Catarrhal affections of the nose and pharynx can be treated efficaciously in other ways, equally simple, as by the atomizer; and the use of the douche should, generally, be discountenanced by medical men. The following cases illustrate the dangers above mentioned that may occur, notwithstanding in most of the cases the patients were aware that it was highly objectionable to swallow while the fluid was in circulation, for reasons aside from the disagreeable taste of the solution used.

November 9, 1875.—Mr. R., æt. fifty-four. Sharp pain in both ears following use of a solution called "Sanford's Catarrh Cure," injected from a tin cup on a shelf, through a rubber tube placed in one nostril. Pain and noises in ear relieved by treatment, without suppuration becoming established. The following week the apparatus was again used. Violent pain followed immediately, and, after a sleepless night, discharge from the left meatus of purulent matter. An examination showed general inflammation, with a ragged perforation of the drumhead in the inferior quadrant.

December 10, 1875.—Mr. R., æt. twenty-nine. Consumptive. Has used a salt and water injection through the douche three times a day for ozæna. While using it his wife "made me laugh," and a "rush into both ears like a trip-hammer" was felt. Sharp pain followed; the next morning it was agonizing, and there was tenderness behind the left auricle. The drumhead was incised on this side, setting free the accumulated secretion, and relief was obtained. Patient passed from observation, but I am informed that suppuration from the left ear continued until his death, last May, from pulmonary disease.

December 27, 1875.—Mr. B., æt. forty-eight. A strong, hearty man, of active occupation and habits. Six weeks before he came under observation, had pain in both ears, following the use of "Dr. Manning's Catarrh Specific," injected by a douche with fall of two feet. "Dr." Manning's catarrh remedy evidently contains carbolic acid and glycerine, apparently in safe proportions. The ear-ache was checked by hot water, and leeches to the tragus before suppuration became established in the right ear, but there was profuse discharge from the left meatus, coming from the middle ear through an opening in the drumhead. Passed out of observation because he "did not believe that a discharge from the ear should be checked." I am informed that the suppuration, with accompanying deafness, has continued until the present time.

Miss S., æt. nineteen. Chlorotic. Has had ozæna for many years. Has been treated in different ways, and for a month previous has used a Thudichum douche with a fall of about three feet. Salt and water and a solution of tannin were used alternately, morning and evening, with great benefit, so far as the nasal inflammation was concerned. October 4th, "took a fresh cold," and used the douche a number of times during the day, passing a pint of the solution through the nostrils at once. Severe pain in both ears followed the involuntary act of deglutition, occurring the last use of the douche, and a yellow discharge from both external canals appeared in the course of the next day. This patient came to me for advice with subacute otitis media, with profuse granulations sprouting from the orifice in the left drumhead; and a small polypus filled the perforation of the right. A cure was effected after tedious treatment.

Mrs. R., æt. thirty-eight. Mother of eleven children and in delicate health. Used the douche occasionally for "colds in the head." The day previous to first visit "noticed a strange feeling in both ears while cleansing the nose and throat with salt and water." The douche was on a shelf "about three feet over the head." A "jarring noise," gradually increasing, and finally intense pain, brought her to visiting her physician, and I saw the case in consultation. Prompt treatment prevented suppuration, but there were marked symptoms of congestion, injected vessels in the line of the handle of the malleus for twelve days.

Mr. S., æt. nineteen. Chronic catarrh since childhood. Has used one of Dr. Clarke's ear douches for injecting salt and water in the nostrils at intervals for several months. Ten days ago used the douche in the morning as usual, without any untoward symptoms. Shortly afterwards "felt something in the ears," and on making efforts to relieve by the Valsalvian method, tasted salt in the mouth. The relief gained was temporary, and toward night had a "regular ear-ache." This was the commencement of a severe attack of otitis media purulenta, and accompanying impairment of hearing, which, however, yielded to treatment.

HARTFORD, CONN., July, 1876.

THERMOMETRIC OBSERVATIONS PERTAINING TO THE EFFECT OF ALCOHOL ON ANIMAL TEMPERATURE.

BY A. D. FELTON, M.D.,

SYRACUSE, N. Y.

ACCORDING to Liebig and his adherents, alcohol increases animal temperature. If this be true, then, irrespective of other qualities it may possess, alcohol is indicated when the temperature is below normal, as in collapse, and is contra-indicated in fevers; whereas, exactly the reverse of the above is true, if it reduces the temperature, according to the more recently accepted theory of Richardson.

We commenced the study of alcohol feeling a little as we fancy Æsop the hermit did at the audacity of the half-frozen wanderer who could blow both hot and cold; but, after personal investigation, we are disposed to believe both theories are correct; that alcohol is double-headed, and does increase and diminish temperature. The following is a summary of sixty-two hypodermic injections of alcohol, and two hundred and thirty thermometric observations made upon the cat, the result of each day's experiments perfectly agreeing. But we fully appreciate that our investigations are too meagre to allow of definite conclusions, there are so many queries constantly arising which are

susceptible of different solutions, depending upon the size of the doses, frequency of repetition, continuance of the alcoholic diet, time of the thermometric observations, etc.; so that to reach satisfactory deductions is no easy matter. Comparing each day's experiments, we find the greatest change of temperature takes place in about thirty-five or forty minutes after the first hypodermic injection of alcohol, usually three minutes. In the normal cat this change is invariably a reduction of about five eighths of a degree. At the expiration of about * fifty minutes, sometimes later, the temperature usually begins to rise, and at the end of an hour it has recovered nearly half the ground lost, as one-fourth of a degree. Now repeating the injections, and increasing the quantity to four minims, in thirty-five minutes the temperature falls about half as much as after the first injection. At the expiration of the second hour it has recovered the quarter of a degree lost. Now inject five minims of alcohol, and in about forty minutes the temperature falls about half as much as before, or an eighth of a degree; but at the end of the third hour it has risen to the starting-point of the morning, as to normal. We now give an injection of six minims, and in about forty minutes there is a slight fall of temperature; but at the expiration of the fourth hour it has risen a quarter of a degree above normal. Continuing the injections, we commence the sixth hour three-eighths of a degree above normal; but since the increase of temperature continues, until checked by the alcohol, in thirty-five minutes it registers five-eighths above normal; at the expiration of forty minutes it has fallen one-fourth of a degree, plainly showing the effect of the alcohol; but at the close of the sixth hour it again reaches five-eighths above normal.

At another time we gave five-minim doses every hour, and the effect was more decided and prolonged, the temperature not reaching the lowest point until about fifty minutes after the injection, and remaining below normal an hour longer than when using smaller graduated doses; but when it passed the normal, the increase as in the other cases was proportionate to the quantity administered.

On the first days of observation, when we administered the alcohol without much regard for regularity, the temperature rose above normal more quickly, and no reasonable dose would materially effect a reduction; yet the effort at reduction was usually manifest. Although an elevated temperature as the result of alcohol would yield very little to repeated injections, yet the subsequent rise of temperature following the administration of alcohol was always marked. Again we commenced with three minims, repeated in an hour, increasing each dose one minim, and lessening the time between each injection five minutes, until we were administering eight minims every forty-five minutes, the quantity and time thereafter remaining the same; and with an equal daily quantity of alcohol, by thus anticipating the rise of temperature, we were able to keep it in subjection for an hour or two longer than by any other method we practised, but the subsequent elevation took place precisely as in the other experiments. With all our experiments, in about two hours after the last injection the temperature would rise from three-fourths to one and a half degrees above normal, depending upon the quantity of alcohol administered; the larger the total daily quantity the higher the temperature. We estimated that it required from six to ten hours after the discontinuance of the alcohol for the temperature to fall to normal, but the following four to six days showed a reaction in which the temperature fell below normal, in one instance a whole degree on the fourth day.

A cat under observation contracted a sore eye, as the result of which her temperature was increased from three-eighths to one and five-eighths degree. In from forty to forty-five minutes after the first injection of alcohol, her temperature had fallen from three-fourths to one and a quarter degree, at one time falling half a degree below normal, and again to within a quarter or three-eighths of normal; but in an hour it commenced to rise, although the injections were repeated. On three of the four days of fever observations, the temperature did not rise to within less than an eighth of a degree of the morning starting point, and by repeating the injections it remained about half a degree under the fever point of the morning. On the afternoon of the remaining day, the fever rose half a degree above the morning temperature. On each day the immediate effect of the alcohol was a reduction, followed by a rise of temperature, but the latter was not as rapid or marked as in the experiments on the normal animal. Of course we cannot say the temperature would not have fallen without the alcohol; but we are not disposed to believe it a mere coincidence, that on each day it should fall in forty or fifty minutes after the injection. Neither can we say the fever would have increased without the alcohol—we are of the opinion it would not; while it appeared to have an immediate effect in reducing the temperature, we noticed that the increase, following the diminution, was not as rapid or great as when there was no fever present. A cat suffering from poison, for a few days had a temperature of one and a fourth to one and three-eighths degree below normal. In twenty minutes after an injection of five minims of alcohol the temperature rose about half a degree, in an hour a whole degree. In fifteen minutes more it had fallen about a half a degree, when a repetition of the alcohol caused it to rise, and thus by repeating the dose the temperature could be raised to normal, and ultimately a little above, only to drop on discontinuing the injections; but after the second dose the temperature would remain nearly at normal, with intervals of two or three hours between the doses, and we inferred a fever would result if the alcohol was repeated too frequently. In a case of collapse occurring in practice, the treatment being hypodermic injections of alcohol, the carefully noted thermometric observations perfectly agree with the above experiments. In this case the temperature fell ten and a half degrees in twenty-four hours, four and a half degrees below normal, the patient apparently being moribund. In two hours' time we administered four injections, and afterwards frequently gave a few drops of whiskey by the mouth. We are now inclined to believe the alcohol was repeated too frequently, and was instrumental in causing, or at least in increasing, the high fever which followed in two or three days.

In our experiments, the vaginal temperature was taken with the bulb of the thermometer well inclosed. The normal temperature was 101½ F., and each injection consisted of from two to eight minims of alcohol proof spirits, largely diluted; but we usually commenced with three minims, as we found that less than that quantity possessed little or no depressing power over the temperature. After the first dose it was necessary to increase the quantity in order to produce the same effect, but it never occasioned intoxication. One or two minims would not lower the temperature

* We are forced to make frequent use of the word *about*, for in such experiments an *exact* correspondence of time could not be expected.

unless it was the first dose, and not usually then, but a slight subsequent elevation of temperature occurred sooner than when it first caused a reduction.

In conclusion, alcohol first reduces the temperature of the normal animal, then raises it above normal. When repeated, its immediate tendency is to check an increase of temperature, but after a little, a rise usually follows, and is proportionate to the amount of alcohol injected. In the feverish condition it temporarily diminishes the temperature, and is disposed to prevent an increase of fever. In collapse it does not further lower, but raises the temperature to normal, and beyond, if too frequently repeated; therefore, we would be governed by the thermometer in the administration of alcohol in such cases. In brief, the tendency of alcohol is to first depress, and then elevate, the previously normal temperature, and to correct an abnormal temperature.

COCA AND ITS ALKALOID COCAIN.

By ISAAC OTT, M.D.,

DEMONSTRATOR OF PHYSIOLOGY, UNIVERSITY OF PENNSYLVANIA.

Some time ago, in a pamphlet* published for private distribution, I detailed some experiments made with this substance. As the action of coca has lately been a subject of remark in the medical journals, I send you the following:

The experiments were made with coca leaves from Schering of Berlin, and cocain obtained from Trommsdorff. The succeeding experiment was made upon myself.

After a small dinner, with a cup of coffee, I masticated coca, swallowing leaves and saliva. First, increased salivation; warmth of buccal mucous membrane, which extended to stomach; the taste of leaves at first rather bitterish, but at length sweetish; numbness of buccal mucous membrane; the heat of the skin seemed increased, and the physical forces seemed greater. In thirty-five minutes a slight disposition to move about. In two hours and a half ten grammes eaten, and some intoxication present; co-ordination somewhat impaired; muscular strength seemed weakened; a sort of paresis; disposition to be left alone; sitting; going into reverie, with frontal pain; tinnitus aurium; ears feel as if I had been blowing a wind instrument; pupil slightly dilated. In three hours, somnolency; frontal pain and fulness about ears continues; disposition to close eyelids; general numbness of whole body. In three hours and twenty-five minutes 29 cubic centimetres of water taken; mouth is hot and dry; nervous urine passed. In three hours and forty-five minutes, general numbness; reveries; holding of respiration, as in deep thought. In four hours I have taken 19½ grammes of coca; the remaining were chewed, and the saliva only swallowed; somnolency disappeared; mind bright and clear. In five hours, I have taken 28 grammes; pupil more dilated; slight supper taken, no coffee, but water; the supper seemed to bring down the action of the coca. In seven hours and forty minutes, the coca being gradually chewed, frontal headache returns with fulness of ears. In eight hours and forty-five minutes 60 grammes of coca have been chewed; loquacity; eyes brilliant and moist; at length speech becomes thick; am in high spirits and full of hopes. In ten hours and fifteen minutes frontal headache again coming on; drowsiness; then retire, but am unable to sleep. After a few hours, deep sleep comes on, but is disturbed and not prolonged. Arise at 7.30 A.M.; face pale; eyes seem dry; lips bluish; take a light breakfast without coffee. Since 10.30 P.M. last night have had frontal pain; sensation in mouth still blunted. At dinner took three cups of coffee, which relieved me, but headache came on during the afternoon; taste blunted during the whole day.

Coca on man increases the pulse, elevates the temperature, dilates the pupil, and decreases the amount of water used and chloride of sodium excreted by the kidneys.

Observations made with cocain on lower animals gave the following results:

In small and large doses it causes loss of co-ordination and decrease of motor power; it does not paralyze the anterior columns of the spinal cord.

In small doses it increases the sensibility, which causes general convulsions upon irritation. Large doses abolish the functions of the posterior columns and sensory nerves.

When gradually introduced into the system, it kills by stoppage of respiration. It reduces the pulse and arterial tension momentarily and afterwards increases them. This effect is a result of an action on the heart and vaso-motor centre. It does not paralyze either the pneumogastrics or the vaso-motor centre situated in the brain.

It first excites and then paralyzes the centres of respiration.

The pupil is dilated, and the temperature after a depression rises.

On striated muscles the course of contraction, as registered by Marey's comparative myograph, is similar to that with veratria.

If coca and cocain are compared with coffee and caffein in their physiological action, the result will be that they are very similar, and that coca and its alkaloid should be classed among the excitants, of which coffee is the chief example.

Easton, Pa.

CASE OF NECROSIS OF INTERNAL EAR, FROM CHRONIC SUPPURATION OF MIDDLE EAR.

TREATED AT DR. AGNEW'S CLINIC, MANHATTAN EYE AND EAR HOSPITAL, NEW YORK.

Reported by J. OSCROFT TANSLEY, M.D.,

NEW YORK.

Monday, May 1, 1876.—Thomas H——, sixteen years old. Has had otitis media suppurativa chronica since five years of age.

Cause, at that time, supposed to be an attack of measles. Has been treated occasionally during this time, but with little success.

The reason for this lack of success seems to have been a want of due appreciation of its seriousness, and, of course, the accompanying carelessness in attending to the affection, rather than any peculiar unmanageableness of the disease.

The discharge continued occasionally in varying amounts, until about five years ago, when, after going in sea-bathing, a severe and acute pain was experienced upon the left side of the head, and accompanied by a swelling behind the left ear. The swelling was poulticed, and in a short time broke and discharged considerable matter. Since that time it

has never healed, but has continued to discharge more or less.

Thus it would seem that both ears have suppurated for ten or eleven years, and the openings in mastoid region have existed and suppurated for five years. About one year ago the mouth became drawn to one side, and he was unable to close the left eye. Considerable pain has been felt in the head and side of the head, and also behind the sterno-cleido-mastoideus muscle, also a dizzy feeling occasionally; but I was unable to gain any information as to the character of the pains, whether dull, heavy, shooting, or lancinating, or any peculiarity in the dizziness.

Present appearance: facial paralysis on left side complete; unable to move or use the muscles supplied by left portio dura at all.

Both ears running and full of pus; left ear also has a hard substance like bone, presenting at external meatus.

Left processus mastoideus tender and in an ulcerous condition, and showing two points at which pus is oozing. Hearing distances: Right, $\frac{4}{5}$; left, $\frac{0}{5}$.

Treatment.—Right ear was syringed and a large perforation found in membrana tympani, and appearing as usual in otitis media suppurativa chronica of such long standing, but no polypi or granulations. Hearing distance much improved.

Left ear syringed externally to clear away the pus, and then seizing the presenting bony mass with a pair of polypus forceps, and by rocking slightly, and at the same time using traction, it was extracted. This mass of bone and pus measured about three-eighths inch in diameter and three-fourths inch in length; and upon being macerated was found to consist of the bones of the internal ear—that is, the cochlea and semicircular canals.

The ear was carefully syringed out, and water was seen to ooze out of the two openings behind the ear on the processus mastoideus.

The probe was not used to investigate the sinuses. Upon examination now, after having syringed the ear, quite a cavity was seen, and lined seemingly with healthy granulating matter.

The patient was seen by Drs. Agnew and Webster, the former advising free incisions over the mastoid and opening of the sinuses; but finally it was decided to let the patient wait for a day or two, or until more positive indications for cutting should be manifest, as pain, etc.

Eustachian tubes were permeable to Politzer's method of inflation.

An instillation of argt. nit. gr. x. ad ℥ i. was used, and a solution of zinci sulphas, gr. iv. ad ℥ i., was given to be used in right ear only, and three times daily.

Advised to syringe both ears several times a day with warm water.

Wednesday, May 3.—Patient came and professed to be greatly relieved, and certainly looked much better. Says his ears have not run so profusely since he has been treated. Probe was passed into the upper opening on mastoid, and was found to pass directly into the external canal, opening into it about one-half inch from external meatus. Consulting with Drs. Webster and Pomeroy, it was thought advisable to still further postpone the cutting of the tissues over mastoid, because of the marked improvement without cutting. Syringing and instillation same as Monday, and same treatment advised as then.

Friday, May 5.—Patient presents a much improved appearance; has had no pain of any kind, or any unpleasant feelings. The cavity previously noticed seems to be filling up with granulation matter, but having a healthy appearance.

Monday, May 8.—Says he is feeling better every day, and has no trouble with his ears, and they run but little.

Wednesday, May 10.—Still improving; has no running from ears, and although the ears have not been cleansed since early this morning, I can find no pus in any part of either ear. In left ear there seems to be a new membrana tympani forming.

Friday, May 12.—A more careful examination of left ear to-day shows the membrane noticed on Thursday to be thin and continuous with the epidermis of the external ear, more cicatricial than membranous in character, and laying upon the inner wall of middle ear, leaving no cavity in the posterior portion; but in the anterior part it is deflected from the inner wall of middle ear over the opening of Eustachian tube to the anterior wall of external canal, leaving here a small cavity. In the central part of anterior portion there is a perforation, or perhaps, better to say, an unformed part through which air may be made to pass by the Valsalvian method.

Very little suppuration in either ear. No pains or bad feelings. Same treatment continued.

July 14, 1876.—Since last date the patient has presented himself regularly at clinic, and has had no unfavorable symptom. Left ear seems to have entirely ceased to suppurate, and to persons not skilled and experienced in examination of ears, seems like an ordinary membrana tympani with a small perforation anteriorly; but it can be easily demonstrated by Seigle's tympanoscope that there is no tympanic cavity, and this seeming membrane has more of a cicatricial appearance and character.

It is hardly necessary for me to say that the small bones of middle ear, as malleus, etc., are not present.

Facial paralysis is still present, remaining unchanged from his first appearance, notwithstanding the fact that he has received the best of treatment for this paralysis in the neurological department of Manhattan Hospital, under the direction of Dr. Seguin.

There is, in all probability, a solution of continuity of the left portio dura in its passage through the petrous bone.

The openings in mastoid region have entirely healed.

Progress of Medical Science.

Treatment of certain Forms of Acne.—Dr. Chantry claims that he has obtained gratifying success in the treatment of rebellious cases of acne of the tuberculous and hypertrophic variety, by the use of iodide of sulphur internally in combination with Hardy's lotion externally. He gives at first one, then two or three of the following pills: ℞. Sulphur. iodide, gr. ss.; Extr. solani dulcamarae, gr. ij. M. He employs also the following lotion: ℞. Aquae, ℥ iijss.; Tr. benzoin, ℥ i.; Potass. sulphuret, ℥ i. M. A teaspoonful in lukewarm water, to be used morning and evening. (Hardy.) If this lotion causes too much irritation, it must be replaced by lotions of filtered bran-water. In some cases the iodide of sulphur causes gastralgia, and its use must be discontinued; but if this does not occur, a noticeable amelioration of the affection is found in about twelve to twenty days

The hard, purple elevations which surround the tubercles slowly soften and become less swollen, the usual desquamation of the epidermis takes place, and soon nothing remains but a diffuse, pale congestion, which disappears slowly, and is often succeeded by triangular cicatrices.

In a case of acne rosacea of the face, of nine months' duration, which had resisted several methods of treatment, the iodide of sulphur could not be borne, and iodide of potassium was given instead, in doses rapidly increasing to a drachm a day. At the same time the diseased parts were rubbed briskly every evening with a sulphur pomade (15 sulphur to 30 lard). In fifteen days the cure was almost complete, and two months later there had been no return of the disease. —*Lyon Médical*, June 18th.

Anatomical Observations on Diphtheria.—Prof. Bizzozero, in *Il Morgagni*, No. 3, 1876, gives the results of his studies on the alterations of the spleen and of certain hæmatopoetic organs in membranous inflammation of the stomach. He found the splenic pulp full of red globules. The Malpighian corpuscles, in addition to the usual lymphatic elements, presented a moderate number of small granules of fat, numerous small granules becoming pale on the addition of acetic acid, and large nucleated cells containing a certain number of fatty granules.

The Peyer's plaques were much tumefied; their superficies were irregular, with irregular depressions and elevations, and a reticulated disposition. The follicles were constituted of the usual lymphatic cells, but they were more granular, containing numerous fatty and albuminoid granules.

Bizzozero found also on the internal superficies of the stomach pseudo-membrane, apparently similar to the croupous exudations existing on the mucous membranes of the pharynx, tonsils, etc.—*Lo Sperimentale.*

On the Influence of Traumatism on Pregnancy.—M. Guéniot recently read a paper on this subject before the *Société de Chirurgie* of Paris, his observations being based on an analytical study of 240 cases of injuries and wounds of all sorts received during pregnancy, including also surgical operations performed on pregnant women. In closing his paper, he embodied the results of his studies in the following conclusions:

I. When the traumatism affects a pregnant woman who is in a state of perfect health (woman healthy, uterus healthy, products of conception healthy), it exerts as a rule no prejudicial influence on the pregnancy, whatever may be its variety, and, to a certain extent, whatever its intensity. To this rule there are the three following exceptions:

1. When the injury implicates any part of the genital zone, that is to say, the vulvo-uterine canal, the perineal or the anal region, the pregnancy is not infrequently cut short. This unfavorable result, moreover, seems to depend more on the duration or repetition of the traumatic act than on its severity.

2. Whatever may be the seat of the injury, if there be great loss of blood within a short period of time, the pregnancy is seriously menaced and the life of the woman more or less compromised.

3. Finally, if the injury be secondarily aggravated by erysipelas, phlegmon, angioleucitis, or other inflammatory complication, there is danger of abortion.

II. When the gestation is complicated by some pathological condition, such as abnormal irritability of the uterus, disease or excessive size of the product of conception, albuminuria, etc., any injury, no matter how slight it may be or what region it may affect, will as a rule excite premature expulsion of the ovum. In this case the true cause of the abortion is to be found in the previous pathological condition, organic or functional, that complicated the pregnancy, and not in the traumatism, which simply plays the part of adjuvant, or exciting cause.

III. In view of the extreme difficulty, and often even impossibility, of diagnosticating some of these morbid conditions (abnormal irritability of the uterus, disease of the ovum, etc.), it is necessary to be very cautious about advising surgical operations during pregnancy. If the operation involve the genital zone, pregnancy presents an absolute counterindication to its performance, except in cases of necessity.

IV. Finally, with regard to the medico-legal aspect of abortion, in order to properly appreciate the influence of the injury on the abortion, it is absolutely necessary to know the condition of the different parts of the ovum at the moment of their expulsion.—*Le Mouvement Médical*, June 17th.

The Electrolytic Treatment of Tumors.—Dr. Julius Althaus, of London, thinks that the limits of the usefulness of electrolysis in the treatment of tumors are now so thoroughly ascertained, that they will be neither notably enlarged nor diminished by future observations. The following is a short resumé of his latest conclusions as to the varieties of tumors in which electrolysis is useful:

1. *Nævus.*—Electrolysis possesses undoubted advantages over all the other methods of treating this variety of tumor. The ordinary round, flat nævus, which is elevated but little above the level of the skin, is often cured by a single electrolytic application; but the large port-wine spots often require half a dozen sittings. Dr. Althaus uses for the operation from 10 to 15 cells of Daniell's battery, both poles being introduced into the tumor. As soon as the circuit is closed the destruction of the nævus begins, the blood-vessels and skin seeming to wither up rapidly. The destruction takes place most actively in the neighborhood of the positive pole. The current should not be too strong nor continued too long in any one spot, or it will leave a cicatrix. After the operation, the surface should be covered with a gold-beater's skin, but no dressing is necessary, for there is no discharge and no pain. The scab falls off in ten to fourteen days, leaving a healthy surface that gradually assumes the appearance of the neighboring skin.

2. *Bronchocele.*—Electrolysis is less painful and less dangerous than the usual surgical treatment of the cystic form of goitre. Dr. Althaus introduces two or three needles connected with the negative pole of the battery into the cyst, the positive electrode being applied to the skin in the form of a moistened sponge. The current decomposes the fluid in the cyst, and converts the solution of chloride of sodium into a solution of caustic soda, which cauterizes the secreting membrane of the cyst, and prevents the production of more fluid. Two to six applications generally bring about a cure.

The hypertrophic bronchocele is much less amenable to treatment, and is generally let alone by surgeons. When, however, it becomes dangerous by pressure on important structures, electrolysis is indicated, and may be advantageously combined with injections of tincture of iodine. The latter breaks down the internal structure of the tumor, especially when it is old and firm, and so secures a freer passage for the electric current through the mass. In recent cases the injections may be omitted.

3. *Atheroma.*—Electrolysis removes this variety of

tumor quickly, and without risk, and leaves no cicatrix. The action is more rapid when both poles are introduced into the tumor, than when the negative alone is used.

4. *Recurring Fibroid.*—As the knife fails to cure this variety of tumor, Dr. Althaus thinks that electrolysis should receive a fair trial. The results he has obtained with it so far have not been particularly encouraging, probably because in all his cases the tumors had attained enormous size, and had existed a long time. In one desperate case, on which Sir Jas. Paget, Sir Wm. Fergusson, and Mr. Cesar Hawkins had refused to operate, electrolysis relieved the intense pain and caused a diminution of the size and hardness of the tumor; but the treatment could not be followed out for a sufficient length of time to give positive results, as the patient was unable to remain in London.

5. *Cancer.*—Although electrolysis cannot replace the knife in the treatment of primary carcinoma, it often produces excellent results in epithelioma and recurrent cancer. It cannot remove the cancerous diathesis, but it relieves the pain, enables the patient to sleep, improves the appetite, and strengthens and quiets the entire system, and so renders the last months of life more bearable.—*Berliner klin. Wochenschrift*, April 17th.

Ammonæmia.—At the meeting of the *Aerztlicher Verein* of Marburg, on February 9th, Prof. Roser exhibited the bladder of a young man who had suffered from calculus. No operation had been performed, because, when admitted into the hospital, he had symptoms of pericystitis with marked collapse. The bladder presented an ulcerated perforation, and the ammoniacal urine was infiltrated as far as the inguinal ring. The professor recounted a number of similar cases of ammoniæmic collapse, from which he deduced the following conclusions:

1. Acute ammoniæmia, which is caused by absorption of decomposed urine, produces marked collapse with low temperature of the blood.

2. A low temperature in cystitis and pyelitis may be considered diagnostic of ammoniæmia.

3. When the source of the ammoniæmia is removed without delay by cutting into the urethra, the bladder, or the pelvis of the kidney, the symptoms of collapse often disappear.

4. Ammoniæmia deserves more attention on the part of surgeons than it has heretofore received.—*Berliner klin. Wochenschrift*, June 19th.

Bromide of Arsenic in the Treatment of Epilepsy.—Dr. Th. Clemens, of Frankfort-on-the-Main, has employed bromide of arsenic for twenty years in the treatment of diseases of the nervous system, and especially of epilepsy, and claims that he has obtained astonishing results with it. He uses the liquor arsenic. bromat., and gives one or two drops in a glass of water once, or, if necessary, twice daily. These minute doses may be given for months and even years, without producing the usual unpleasant effects of a long-continued arsenical course. All his cases of epilepsy have been markedly relieved and improved by this remedy, but in only two cases has it produced a complete cure. In many cases of incurable epilepsy, complicated with idiocy and deformities of the skull, the fits were reduced in number from twenty in the twenty-four hours, to four or even two, a result that has been obtained by no other treatment. In connection with the bromide of arsenic, an almost exclusively meat diet is advised. The patients should be as much as possible in the open air in the daytime, and their windows should be kept open at night. Unlike bromide of potassium, this remedy does not require to be given in increasing doses, and instead of interfering with digestion, improves the nutrition and strength. Dr. Clemens has employed the following formula since 1859, and thinks that it ought to replace Fowler's solution, which is irrational in its composition and uncertain in its action. This solution becomes stronger with time; the chemical union of the bromide with the arseniate of potash becoming more and more perfect.—℞ Pulv. Arsenic. alb., Potass. carb. c. tartar., ää ʒ i.; coque cum aqua destil. lb. ss. ad solut. perfect.; adde, aq. evaporat. restituta, aquæ destil. ℥ xij., dein adde brom. pur. ʒ ij., refrigerat. stet per sufficient. temp. ad decol., S. liq. arsenic. bromat.—*Allg. Med. Central-Zeitung*, May 24th.

On some Vesicular Diseases of the Tongue.—Dr. Stokes contributes to the *Dublin Journal of Medical Science* a paper in which he claims that there are "three distinct conditions in which a vesicular disorder of the tongue may be found." One is a complaint first described by Earle in 1822, and since called "Earle's Disease," in which the entire thickness of the tongue was pervaded by minute, semi-transparent vesicles; the clusters were in some cases separated by deep clefts, which discharged a fetid, irritating sanies, and the slightest injury caused the diseased part to bleed profusely. The disease gradually yielded to a strict attention to perfect quiet and cleanliness, combined with large doses of hyoscyamus, as much as ʒ i. of the extract having been given daily. The second form is one which does not yield to treatment, and is illustrated by a drawing from the museum of the Richmond Hospital. The disease consists in a mass of vesicles with pink bases and semi-transparent tops of hemispherical form, forming a circumscribed tumor occupying nearly half the tongue. There is no induration of the surrounding parts. The growth occasionally swells a little and is painful, but has undergone very little alteration in size or appearance during the twenty or more years it has existed. The pain and irritability are relieved by the use of a weak solution of citric acid as a lotion, and of hyoscyamus, but no treatment has succeeded in causing a radical improvement. In the third form the vesicles are superficial and dependent on gastric irritation, or on the presence of bad teeth, or of a tumor, or ulcer of simple or specific character, or lastly, may be due to the herpetic diathesis.—*Dublin Journal of Medical Science*, May, 1876.

Some Forms of Dyspepsia.—A clinical lecture on the above subject, by Dr. Francis Delafield, is published in Vol. II., No. 1, of the *American Clinical Lectures*. Dr. Delafield holds that in many cases of dyspepsia only one of the digestive organs is at fault, and that a proper analysis of the symptoms will enable the physician to discover whether it is the stomach, the small or the large intestine, or the liver that is at fault. The symptoms of stomach dyspepsia are nausea and vomiting, pain, loss of appetite, eructations of gas and of sour fluid, and in old and severe cases loss of strength and flesh. The pain always follows the ingestion of food, and is relieved by vomiting. The lesions consist in a chronic inflammation of the mucous membrane of the stomach, with a loss of power in the muscular coat. The inner surface of the organ is coated with tenacious mucus, the connective tissue between the gastric tubules increased in amount, and the tubules themselves atrophied. The stomach may be very small or much dilated. The milder cases can often be cured by regulating the diet and life. In the severe cases Dr. Delafield recom-

mends washing out the stomach with the stomach-pump, and cites two very bad cases that he cured with this treatment, all drugs having previously been proved useless.

In dyspepsia due to functional derangement of the small intestine, the principal symptom is pain, which may be referred to any part of the abdomen, is constant and dull in character, and has no special relation to the ingestion of food or its quality. It is generally relieved for a time by liquor. It may come on at regular intervals. The appetite is good, and the bowels are regular. There may be nausea, especially in the morning, but it does not follow eating, and there is no vomiting. The patients are languid and feel good for nothing, and are apt to become hypochondriacal. In the treatment of this form cubebs, ipecac, and assafœtida are useful; riding on horseback and travelling are to be recommended.

Dyspeptic symptoms dependent on disordered functions of the liver are very common. The great majority of the cases of dyspepsia met with in Dr. Delafield's clinic are cases of liver dyspepsia. The Doctor divides these patients into two classes: the first including persons of florid complexion and well-developed muscular and fatty tissues; and the second, those of pallid complexion, spare figure, and feeble muscles. In the first class he thinks that the symptoms are due to derangement of the functions of the liver, which should effect the destructive metamorphosis of the albuminoid substances, so that the patients receive a full supply of the nutritious portions of the food, but do not get rid of the excrementitious. In the second class, on the other hand, the excretory and destructive functions of the liver are well performed, but those functions which should effect the assimilation of fat and peptones are disordered, so that the patient is imperfectly nourished. The usual symptoms of the second class of cases are headache, curious nervous feelings, such as local chilly or pricking sensations, dull pain in the right hypochondrium, constipation, flatulence, and sleeplessness. The urine is normal, or contains an increased amount of oxalate of lime, or sometimes stellate crystals of phosphate of lime. This condition is often very intractable to treatment. The diet should be full and nutritious; wines and other liquors are often useful, and cream and cod-liver oil are sometimes indicated. Strychnine, aloes, podophyllin, etc., must be given to relieve the constipation; bromide of potassium, assafœtida and guarana to allay the nervous symptoms and restlessness; and mineral acids as a tonic. Exercise in the open air is to be insisted upon, and in young persons the daily use of the cold bath. In the first class of cases the symptoms are generally vertigo, uncomfortable feeling in the head, inability to apply the mind to business, and partial loss of memory. The appetite is usually good, the bowels irregular, and the urine loaded with uric acid or the urates. The treatment should consist mainly in total abstinence from all alcoholic drinks, and from tobacco, and in exercise in the open air. The natural alkaline and sulphur waters are often useful, but no regular plan of treatment, as regards drugs, can be laid down.

Dyspepsia due to derangement of the large intestine is often met with in old people, and seems to depend either on a loss of power in the muscular coat, or on a loss of sensibility in the mucous coat. The principal symptom is constipation, with headache, flatulence, uncomfortable feelings in the abdomen, etc. The constipation alternates with diarrhœa, the passages being small and painful, and not followed by a feeling of relief. All these symptoms are consequent on the accumulation of hardened fæces in the rectum, which, despite the diarrhœa, is never entirely emptied. The treatment must consist first in clearing out the large intestine by means of a laxative, aided, if necessary, by scooping out the hardened fæces with the finger or some convenient instrument, and subsequently in the use of aloes and strychnine, and regulation of the diet.

Injecting the Male Bladder without the Aid of a Catheter.—For the last year Prof. McGuire, of Virginia, has made use of the following simple procedure in injecting the male bladder. He takes the ordinary rubber-bag syringe used to inject the bladder through a catheter, the nozzle of which is provided with a stop-cock, and tapers to a point. The bag is filled with warm water, all the air being carefully excluded, and the nozzle oiled and introduced into the urethra for an inch or an inch and a half. The urethra is then gently compressed around the nozzle of the syringe, the stop-cock turned, and, by gentle and continuous pressure on the bag, the water forced along the urethra into the cavity of the bladder. It is important to avoid all rough manipulations, and to inject the fluid slowly. With a little practice the patient can perform the operation quite readily himself. This method of injecting the bladder is especially applicable to those not rare cases in which the introduction of a catheter causes pain or urethral fever. The warm water may be medicated, but it is important to remember that the mucous membrane of the bladder is more sensitive than that of the urethra, and consequently these injections must be milder than simple urethral injections would need to be.

Prof. McGuire has employed this method with advantage in a case of malignant vascular tumor of the bladder, and preparatory to the operations of lithotrity and lithotomy. In a case of severe cystitis following the first of a course of lithotrity sittings, distending the bladder with water by means of the bag syringe was followed by such immediate and great relief that he was able in a few days safely to employ the lithotrite again. In a case of severe strangury, the same proceeding gave almost complete and immediate relief. It is, however, in cases of cystitis and enlarged prostate that Prof. McGuire anticipates most benefit from this method of injecting the bladder. In these cases, the introduction of the catheter and its necessary retention in the bladder for some minutes, often cause urethral fever and increased irritability of the bladder that more than counterbalance the good the injection may have done. The frequent introduction of the catheter, moreover, in cases of chronic hypertrophy of the prostate, undoubtedly has a tendency to increase the already existing trouble. In these cases the bag syringe can, with few exceptions, be substituted for the catheter. Four or five ounces of warm water, simple or medicated, are to be injected and retained for a few moments and then expelled. What will remain in the bladder will be, not the phosphatic, irritating urine that was there before the operation, but a small portion of this diluted with the water. By repeating the injection the residual fluid can be made entirely unirritating.—*Virginia Medical Monthly*, July, 1876.

A Benefactress of Mankind.—A Mme. Hagelle has bequeathed to the *Assistance Publique* of Paris the sum of two million dollars, to establish somewhere in the environs of the capital a hospital for the aged, the infirm, and the incurable.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, September 9, 1876.

LENGTHENING THE TERM OF HOSPITAL SERVICE.

THE reorganization of the New York Hospital has given the governors of that institution an opportunity for canvassing the different methods which may be suggested for increasing its efficiency as a charity, and of expanding its influences for professional advancement. Not long since we referred to the report upon the Cottage plan of organization which was called forth by a special resolution, and now our attention is directed to the subject of the internal administration of the "New Hospital," which also at the suggestion of the Board is the basis of a report from the Medical Staff. Assuming that there is a great disproportion between the amount of work to be done and the number of persons appointed to perform it, the Medical Board suggests that the number of the attending staff be reduced, and that the term of service be increased. The following is the plan which, in the words of its advocate, Dr. Sands, is calculated to create "a much needed reform in hospital management":

"I. The assignment to each division of the hospital, of one attending physician or surgeon upon whom, together with an assistant physician or surgeon, shall devolve the entire care and responsibility of the service throughout the year. It is assumed that in the plan recommended the assistant shall, in addition to aiding the attending physicians and surgeons, perform regularly the duties of the dispensary department.

"II. The reduction of the present number of the attending staff so that there shall remain but three, namely: one attending physician and two attending surgeons, to each of whom shall be assigned one-third of the entire number of beds which the new hospital building is designed to contain.

"III. The establishment of a rule forbidding the members of the attending staff from holding similar positions in other institutions."

The principle involved in the propositions is correct, but the change will, we think, be too radical for the purposes of experiment on the part of the governors. There is no doubting the fact that the patients will in the main be benefited by a longer service on the part of the attending physician or surgeon, but the question arises whether the same end might not be attained by dividing the services among a larger staff. Dr. Hackley, one of the attending physicians, offered a modification of this plan which seems to be more practicable in that it does not involve the necessity of reducing the present staff. He advises, so long as the accommodations of the hospital are limited, that the medical staff be allowed to decrease by resignation and death, to four physicians and four surgeons; that one-half the beds be surgical and one-half medical; that the terms of service be six months each, ending respectively on August 1 and Feb. 1; and that the physicians and surgeons shall draw lots, the four of each set being the active attendants for the year.

Every one who has acquainted himself practically with the internal administration of our hospitals must admit that the system has been very defective. The eagerness with which medical men, especially college professors, seize upon hospital positions, and their greed in holding as many as possible, have engendered a carelessness in the performance of their duties which has been very prejudicial to themselves, to the patients, and to the profession at large. As a rule the size of the staff in our hospitals is too large, and the services, in order to be equally divided, are too short. This is especially the case during the winter term of lectures at our colleges, when each professor, anxious to have his share of clinical opportunities, is willing to reduce his period of service to suit the emergencies of the situation. The natural result has been that the attending physician or surgeon cannot acquire a knowledge of his cases before he is called to give place to his successor, and with the exception of a few patients upon whom he may deliver clinical lectures, he leaves the entire charge of his wards to the senior member of the house staff. We speak from actual experience when we assert that this is the rule rather than the exception, and that the attending surgeon or physician is oftener apt to walk through his wards as a matter of form than of duty.

In referring to the proposed change in the internal administration of the New York Hospital, we wish to speak of them not only in connection with that institution, but of others of its class which also call for them in our larger cities. In view of their necessity, it is a fortunate circumstance that the Medical Board representing one of the oldest and most reputable charities of the country, shows such a strong disposition to lead the van of reform. The details of the plan may be open to more or less criticism, but the principle is beyond question, and must commend itself to the careful consideration of those who have the

true interests of these institutions at stake. Although this is but one of many of the reforms needed in hospital management, it is a very important starting point for others which will naturally follow. In this connection we would refer to the resolution forbidding any one connected with the hospital from holding a similar appointment elsewhere. If the lengthening of the term of service accomplishes no more than a strict adherence to the one appointment system, it will be attended with an unquestioned good to the profession at large in giving many worthy men a chance to benefit by hospital experience, who are shut out by uncompromising monopolists. Very many medical gentlemen hold two such appointments, not a few three, some four, and one as many as eleven. The sweeping application of the one appointment rule would convert many of these gentlemen into public benefactors in proportion to the number of extra positions they may hold. From this point of view the privileges of the gentleman with eleven of these appointments would be envied by the medical world at large.

CAUTION MARKS.

The American Pharmaceutical Association at its last annual meeting appointed a committee to confer with the American Medical Association, and to suggest to that body the advantages which would result from the adoption of means of greater protection to patients in prescribing. It was recommended as a measure towards this desirable end that a list should be selected of dangerously active medical preparations, and their maximum doses noted, as well as the maximum quantity that may be safely administered during twenty-four hours—such quantity not to be exceeded in prescriptions without the addition of some caution mark previously agreed upon by the physician. In case a prescription is presented to be compounded with articles ordered in quantities exceeding these maximum doses thus laid down, and without the caution marks annexed, the pharmacist must return the prescription to the physician, in order that the requisite caution mark or marks shall be added. It was stated that in some European countries a list, such as is here suggested, is framed by legal enactment, published by authority, and appended to the Pharmacopœia. It thus becomes obligatory on every pharmacist. The President of the American Medical Association appointed as a Committee of Conference on its part three gentlemen, well known as teachers and authorities—Profs. Stillé, Biddle, and Rogers, who are resident on the very spot most available for consultation. The Pharmaceutical Association will meet at Philadelphia about the middle of September, and will doubtless take immediate action in the premises. Whatever recommendation the Committee may make that will jointly affect the interests of the alliterative trio—physician, pharmacist, and patient—will doubtless be well worthy the conscientious observance of all prescribers and dispensers of potent remedies. It would seem but right that the responsibility for intentionally large doses should be placed where it properly belongs. Moreover, it is in the experience of every druggist that an inquiry on his part as to the size of a dose prescribed, or a suggestion to the practitioner that such dose is an unusual one, may be met with a discourteous reception. Rather than risk the loss of so valuable a source of pecuniary profit as is offered in the custom and favor of a multitudinous prescriber, the druggist may be tempted to diminish the amount of the active ingredient without consultation with him, and thus at once destroy, perhaps, the effect for good which might have followed the compounding of the larger dose. It remains to be seen whether the same fear of offending a medical patron may not attend also the neglect of caution marks, should they ever come into use. Some resistance may also be made by heroic dosers to any arbitrary table of maximum doses, beyond the limits of which they are habitual travellers. After all, even when caution marks become the order of the day, thorough education in each profession, and the exercise of a fair share of common sense, must still control both prescriber and compounder.

Reviews and Notices of Books.

Transactions of the Thirtieth Annual Meeting of the Ohio State Medical Society, for 1875. Cincinnati: A. H. Pounsford & Co., Printers, 9 & 11 West Fourth St.

The 214 pages in this volume contain the minutes, the address of the retiring president, a list of deceased, active, and honorary members, and the papers read before the Society, together with the discussions to which they gave rise. Dr. W. T. Ridenour furnished a paper upon the "Pathies" of the day. Some practical points in the Eye Department were presented by Dr. W. W. Seeley. Dr. P. S. Connor related how he used the aspirator in cases of retention of urine. The relation of Consumption to Life Insurance was considered by Dr. W. B. Davis, and provoked quite an animated discussion. Puerperal Blindness was referred to by Dr. W. J. Scott; and the "Prevention of Laryngeal Tumors," by Dr. J. T. Whittaker, stirred up the members who were not skilled in the use of the laryngoscope. This was appropriately followed by a well-written paper upon "The Prurigo of Hebra," by Dr. L. R. Longworth. The *attention* was next called, in a practical manner, to "Symptomatic Ophthalmia," by Dr. E. Williams, and Dr. C. E. Beardsley reported four cases of "Phymosal Paraplegia," all cured by circumcision. Dr. Museraft reported a case of recovery from supposed fracture at the base of the skull; and Dr. W. C. Chapman discussed, somewhat philosophically, "Puerperal Eclampsia." Dr. W. J. Scott also reported cases of what he termed "Railroad Locomotor Ataxis," occurring in conductors and engineers.

The two pages of *errata*, which appear in the posi-

tion of a preface, are unpardonable, and why the corrections were not made upon the proof-sheets is a mystery.

A Practical Treatise on Diseases of the Eye. By Robert Brudenell Carter, F.R.C.S. Edited, with Additions and Test-Types, by John Green, M.D. Philadelphia: Henry C. Lea, 1876.

The English edition of this work was reviewed in the Record about a year ago, and the American edition now published is essentially the same work, though improved by notes and additions of practical value. Some short passages, of little interest to American readers, have been omitted, and a number of inaccuracies corrected; some additional illustrations have been introduced, and a set of test-letters is given by the editor at the end of the volume.

In Chapter VI. there are some important additions made to the surgery of the lachrymal passages, particularly an account of Agnew's operation for laying open the lachrymal sac, preparatory to its destruction by caustics.

A good account is given in Chapter VIII. of Arlt's operation for the removal of pterygium. In Chapter XIV. mention is made of J. F. Noyes' method of advancing the external rectus muscle, modified somewhat by the editor. The prevention of strabismus, and its cure in its incipient and early stages by the use of convex-glasses or atropine, or both, is an important subject, which has been entirely passed over by Mr. Carter, and the American editor has done good service in incorporating a description of it in the work. The latter has also added some practical hints upon the subject of muscular asthenopia in myopes in the chapter upon the uses and selection of spectacles. The subject of the progressive tendency to increase of myopia, and the relation of external and internal recti muscles to this increase have also briefly been considered in the American edition, so that it may fairly be considered of somewhat more value than the English edition.

Correspondence.

MEDICAL CENTENNIAL AFFAIRS.

(From our Special Correspondent.)

Philadelphia, August 19, 1876.

A medical man of this city was anxious, before the Exposition opened, that his son, also one of the profession, should have medical charge of the hundreds of patients who might need his services, at one of the large hotels newly erected in that vicinity. He felt that such an opportunity for pecuniary profit from attention to the ailments of injudicious sight-seers was not available every day, and that the aspirations of his son might be duly gratified while his pocket nerve was correspondingly titillated. He lost no time, therefore, in seeking the proprietor of the hotel with the view of impressing upon him the desirability of such an alliance. That functionary, however, was too far-sighted to grant such a concession, as it was technically called, without himself deriving some advantage from the prospective sickness or sufferings of his guests. Much to the surprise of the father, who had of course expected to secure the position gratuitously, such a fabulous sum was demanded—two thousand dollars, I have been told—that the offer was at once abandoned. Whether any other medical man assumed the duties of the post on such extravagant terms, I am at a loss to say. It is more than likely that the position has not been a very profitable one, for the visitors to Philadelphia have not been, as a rule, those who could afford the luxury of being sick at the rates of charges in which a medical man, with a two thousand dollar concession hanging over his head, would be likely to indulge. Everything else in immediate proximity to the grounds has been a complete and absolute pecuniary failure. Restaurants in endless profusion line the outskirts of the Centennial buildings, but most of them remain almost empty from morning to night. In some cases the proprietor spends most of his time sitting outside his own door, waiting for a transient customer, who only occasionally disturbs his meditations. As a general rule, the visitor to the Exposition spends all his time and money economically inside the grounds, and when he is tired goes home, in total disregard of all outside inducements to tarry. Possibly the invalid follows a similar course, and leaves the hotel doctor wholly in the lurch, in selfish and total oblivion of the concession with which his fees are heavily mortgaged.

The Italian medical exhibit, which we casually passed by in our last visit, is a very rich one—on the catalogue, but not in reality. It is difficult, indeed, to separate from the confused mass into which many of the articles have been promiscuously thrown together, the displays of sulphur made by half a dozen different firms, and of chemicals of all kinds. There are mentioned in the catalogue more than a hundred exhibitors of chemicals alone, in which licorice, olive oil, and cream of tartar play a very conspicuous part. There would be a monotony in examining this line of goods, did the actual display bear any ratio to the length of this printed list. The strictly medical portion of the exhibit includes among other items the "Antisyphilitic Remedy of Dottor Pollini," the merits of which are described in a thick pamphlet, evidently translated by an Italian, who has not fully mastered English. The public are informed at the outset that the price for two hundred years has been ten francs, and has not been changed. The trade, however, are told that "relative deductions are accorded for large acquisitions; to the apothecaries as well as to commercial houses, according the commission." The mayor of Milan appends a certificate that the remedy has been sold in that city for more than a century, from his own personal knowledge, we presume. The same confusion exists in the display of pharmaceutical preparations, almost all of which are inaccessible to the exploration of visitors on account of the careless manner in which they are heaped together. For any good and useful purpose subserved by such exhibit, they may as well have never left the shores of sunny Italy.

We look in vain for the contribution referred to in the catalogue as "microscopic, normal, and pathological anatomical preparations," sent over by the Director of the Anatomical and Pathological Museum of Florence, and presume, as in a number of other cases, they have not yet been received. We are interested, however, in the diagrams representing the apparatus of Colli Clericetti for human cremation, a showy temple, "Edicola Crematina," with sectional views, one of which exhibits a corpse just about ready to pass into the fiery furnace which is to reduce his flesh and bones to ashes. In the same corner we notice a few Italian medical works—Gamberini on venereal and cutaneous diseases, and Manzini and Rodolfi on transfusion of blood. Not far from these is

a case of "sciringhe metalliche flexibili," whose name thus given needs no translation.

Sweden is not at all extensively represented in the Exposition, from a medical point of view. A few chemicals, not of special interest to the physician; several contributions of Aseptin for the preservation of provisions and animal materials; and Amykos for the complexion, and a small case or two of surgical instruments, not deserving separate note, being chiefly for the eye, for vesico-vaginal fistula, and silver catheters, make up almost the entire collection. The Royal War Medical Department, however, makes in the catalogue a special exhibit of surgical instruments for military use, but all we can find, after inquiry from one of the Swedish officials and diligent search, is a sort of medical supply wagon, tightly locked, on which the Geneva cross is a conspicuous feature.

In a large and handsome case in the Swedish department are exhibited, by Prof. Axel Key, specimen numbers and volumes of the Nordiskt Medicinskt Arkiv, edited by him, and numerous popular Swedish works, which seem to be fascicnli of a series of treatises on natural science, by Dr. Gustav Retzius and himself. A handsome illustrated quarto volume lies open, with a full-page colored sectional view of the brain. It is their joint work, in German, "Studien in der Anatomie des Nervensystems und des Bindegewebes."

Passing next to the exhibits of Australasia, India, Jamaica, Canada, and other colonial dependencies of Great Britain, we find much to interest us as physicians. From distant Queensland we notice a large number of specimens of gums, derived from the eucalyptus, iron-bark, blood-wood, etc., castor oil seeds, and samples of dugong oil, used both internally and externally for medicinal purposes. Victoria sends a confused and not well arranged collection of barks and resins of various kinds, in which the eucalyptus is well represented. I notice that many of the foreign countries—most of them, indeed—send specimens of aërated waters, which is, I presume, another name for soda or mineral waters. What object the senders can have in paying the expense of freightage, etc., to such a distance for bottles that on their face give no information, and whose interior is a sealed secret to all visitors, is a mystery. The fault throughout the whole Exposition, applying to medical exhibits as well as to others, is the want of intelligent explanation of things exhibited. Some of the most interesting features of the display would bear very careful study at the hands of the physician; but few visitors will take the trouble of hunting up, in a remote corner of the department, the foreign commissioners or agents, whose only response may be in English so thoroughly broken that no intelligible phrases can be framed from the pieces.

Bagot of Adelaide exhibits numerous small cakes of "Portable Dry Extract of Meat;" and Hood and Co. of Melbourne a very creditable collection of miscellaneous drugs, the only one from Victoria, including soluble chlorodyne, solution of carbazotate of ammonia, phosphorized cod-liver oil, bismuth ore, oil of peppermint, distilled four years ago from the herb grown near Melbourne, and prepared hydrated silicate of aluminium, extracted from granite and employed for the cure and prevention of bed-sores. This firm was awarded prize medals for pure chemicals at Dublin in 1865, and afterwards at Melbourne and Adelaide. In another case is a fine collection of about thirty chemical and pharmaceutical preparations obtained from the eucalyptus or gum tree of Australia, and other indigenous vegetation, which Mr. Joseph Bosisto, one of the Commissioners from that colony, and President of the Pharmaceutical Society of Victoria, has presented to the Philadelphia College of Pharmacy. Eucalyptus is offered in a dozen different phases, such as powder, ointment, solution, cigarettes, oil, tincture, various colored essential oils derived from different species, eucalyptol, etc. It may not be generally known to the profession, who look upon this as one of the new remedies, that four-fifths of Australasian vegetation consists of the eucalyptus, there being in all one hundred and thirty species. Taking it in mass, although the blue gum or "globulus" species is that best known to us, it has a distinctive local reputation as an agent destructive of miasmatic poison. It is said by authorities resident in that country that Australia is pretty free from endemic or miasmatic fevers, and that the latter exist only as the eucalyptus recedes. These effects are thought to be partly due to the fact that the plane of the leaf is parallel to the axis of the tree, thereby allowing free action to the light and heat of the sun on both sides, and that the roots are dispersive and drain water largely from the soil.

From a pamphlet on Victoria now before us, we notice that Mr. Bosisto, in a paper read before the Royal Society of Victoria not long since, dwells on these points, and argues also that the physical geography of Australia differs in no way from that of other countries; that the evergreen eucalyptus exerts its active influence physically, through its root as an absorbent of humidity, and through its abundant leaf surface, and its leaf evaporation of water, oil, and acid under a perpetually genial temperature. Chemically, it acts through its peculiar volatile oil, its volatile acid, and their power of producing peroxide of hydrogen, the plant itself and the air being found by experimental observation to be abundantly charged with these volatile substances. It may be surmised also, while we are on the subject, that so many parts of the world contribute eucalyptus to the Exposition, that more direct attention will doubtless be awakened in the United States to the remedial virtues of certain species of it. South Australia also sends a variety of wines, among which may be mentioned quinine wine, by Bickford of Adelaide.

From the Cape of Good Hope, in addition to a tempting exhibit of about twenty-five varieties of wines and brandies, all of which are in bottles tightly corked, there are dried barks and leaves, many of them of medical interest, with unfamiliar names; bitter bark used in fever cases by the native or Kafir doctors, etc. We also notice a label marked "Witch Doctor's Dress," but we look in vain for the various articles of apparel, which is probably that of the first Adam, minus the fig-leaf. Some "divining bones," consisting of about twenty human metacarpi strung together on a cord, and two "medicine roots" are all that we see of it. A number of specimens of medical barks from the Mauritius, with equally unfamiliar botanical names, are exhibited in that section, some of them belonging particularly to the Quisqualis (liberally translated, what-d'-ye-call-'em) Indians.

India supplies about three hundred specimens of the materia medica, neatly arranged in horizontal cases, including many familiar articles, such as cinchonas, neem bark (the Azadirachta Indica), aconitum, cannabinum, papaver, cassia fistula, etc. From British Guiana are displayed castor and cayenne oils, starches suitable for food, Indian gums, and cassareep, which is the inspissated juice of the roots of the bitter cassava. This juice has an economic aspect, for it is used in making pepperpot, to such advantage that by adding a small quantity of it from time to time to varieties of

animal food, the same pepperpot may be kept in daily use for several years! So says the descriptive card attached to the specimen, and we confess that we are lost in admiration of this potent article, which can daily rejuvenate a mysterious dish so that it will still continue to be the same familiar old pepperpot of years gone by. Let us devoutly hope that the knowledge of its merits as a preserver of this kind of vitality may forever remain unknown to the servers of free lunches, although this is of course a matter in which medical men are not interested.

It seems hardly worth our while to dwell on the small contributions of drugs, etc., sent to the Exposition from these and other distant British colonies, the only slightly interesting feature of which will not bear the elaboration of description. Coming nearer home we reach the Atlantic possessions of Great Britain, Bermuda and Jamaica, with their arrowroot, the Superintendent of the Government Botanical Gardens at Kingston, in the latter country, sending fine specimens of simarubra, baobab fruit (Adansonia digitata), sarsaparilla, cinchona succirubra, c. calisaya, c. officinalis—from all of which it is stated that quinine is made—jalap, mucuna, aloes, etc. This last exhibit is well worth the attention of the medical visitor. Cascarilla and canella barks are also noticeable in the section occupied by the Bahamas. Canada makes a creditable display of pharmaceutical preparations. The principal houses represented are those of William Saunders of London, a very active member of the American Pharmaceutical Association; Lyman, Clare & Co. of Montreal, and Lyman Bros. & Co., Toronto. Many of the elixirs exhibited by Mr. Saunders are labelled "Amer. Pharm. Ass'n.," and a large number of medicated pessaries, suppositories, extracts, etc., are also displayed by him. The Toronto firm just mentioned exhibits fifty pounds of crystallized nitrate of silver in a single jar, which is only one of the features of a very fine exhibit. Several dozen bottles of fluid extracts, of the same color and uniform size, suggest monotony, even if they express quantity and variety of materials. With the exception of a comfortable chair for invalids, by Roy & Co. of Montreal, admitting of motion of the patient in a score or more of varied positions, and some surgical apparatus, spiral spring trusses and artificial limbs, Gross's patent (not the Professor), there is nothing else in the Canadian medical exhibit to comment on.

R. J. D.

FŒTUS SHOT IN UTERO; NORMAL DELIVERY AND RECOVERY OF THE MOTHER.

To the Editor of The Medical Record.

Sir:—The following item was furnished me by Dr. Chas. Berry, of New Ulm, Minnesota, the attending physician in the case:

On the fourth of July last, Mrs. Anderson, of Alfsbury, Sibley Co., Minn., a Swede aged 28, pregnant at about the full term, was shot by the accidental discharge of a pistol in the hands of a young man who was riding by her side in a farmer's wagon. The ball entered the abdomen of the woman two inches above the crest of the right ilium and a little back of the ant. sup. spinous process, and took a downward and forward direction. A little shock was felt, but no serious symptoms followed. In forty hours delivery of a dead child took place, and the pistol-ball was found in its abdomen. Labor was normal in all respects, except that there was some nervous prostration, and recovery was complete.

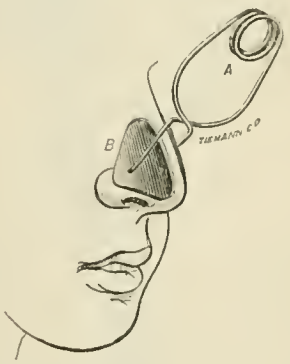
New Instruments.

THE TREATMENT OF EPISTAXIS BY THE NOSTRIL CLAMP.

By SALVATORE CARO,

NEW YORK.

On February 17th, 1875, at one o'clock A. M., I was hastily summoned to relieve Mrs. S., aged 65, who was (as I was informed) vomiting blood. On arriving at her bedside, I found her lying in a pool of blood and almost pulseless. On raising her up, to ascertain whence the blood was coming, she threw up a large quantity of coagulated blood which she had swallowed, and fainted. After washing her face I saw the blood issuing from the left nostril. To ascertain whether it was an anterior or posterior epistaxis, I held her nose firmly within my fingers, and was pleased to see it stop. The bystanding women having refused to hold her nose while I wrote a prescription, I called for a common clothes-pin, and, one with a spring being handed to me, I applied it to the wings of the nose,



and to my delight succeeded in arresting the hemorrhage without further interference. Of course I left it *in situ* and upon removing it ten hours after no blood returned nor has any ever since. Observing the success obtained by the clothes-pin, I devised this little instrument, had it made and perfected by Messrs. Stohlmann and Pfarre, and put it into use. The result having been satisfactory, without exception, I beg of you to call the attention, through your valuable journal, for what it may be worth, of the profession at large, and let it judge of its merit.

As you will perceive, Mr. Editor, this clamp is not intended to arrest an epistaxis of the posterior nares; but, simply, such as originating from the tip and wings of the nose, occur frequently among children and persons exposed to solar heat. The instrument, which is simple, light, and not very costly, is made of a single wire, coiled on the end *A*, and bladed on the two ends *B*. The blades are made to fit the wings of the nose, and the wires are so arranged that by straightening or curving them the pressure may be increased or diminished according to need.

If any practitioner should object to its use, owing

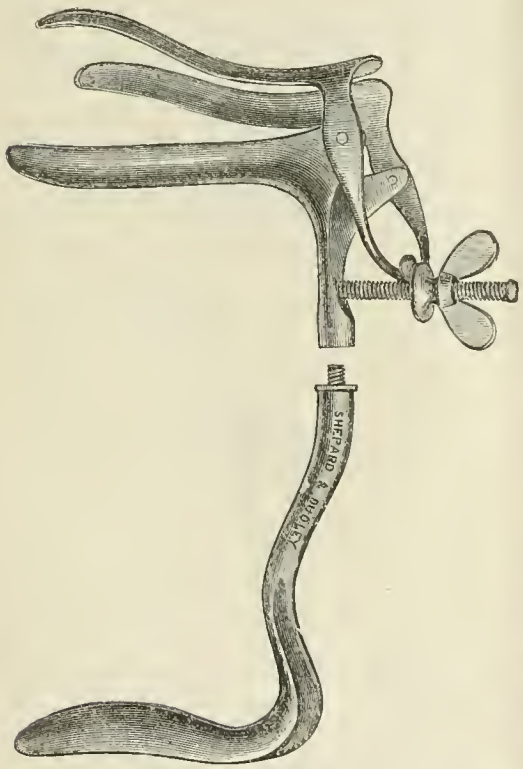
to the inconvenience of wearing it for a few hours, I may properly suggest that the insignificant unpleasantness experienced is vastly compensated; first, by the avoidance of the filthy and often inefficient use of lotions, powders, and plugging, with its unpleasant consequences; and second, by the thorough and speedy manner in which the flow of blood is arrested, and the patient made sufficiently comfortable to be enabled to attend to domestic duties, as though nothing had occurred.

129 West Fifty-third Street.

COMBINED SIMS' & NOTT'S SPECULUM.

By WALTER R. GILLETTE, M.D.

I present herewith a cut of a combined Sims' & Nott's Speculum, which was made at my suggestion two years ago, by Dr. Leonard, of Shepard & Dudley's. I think it is preferable to the instrument



recently devised by F. G. Otto & Sons. Their instrument is a solid Sims' speculum, with the flanges constituting one blade, a Nott's speculum detachable. Its use, therefore, is quite limited to the patient in the semi-prone (Sims') position, as it is extremely awkward and difficult to get the patient's hips near enough to the edge of the table in order to apply it in the supine position.

The instrument illustrated is simply Nott's modification of Cusco's speculum, with a Sims' blade and handle, which can be screwed on when needed. This blade has also Van Buren's curve, for examination of the rectum. It can be used in the supine or semi-prone position of the patient, by detaching or attaching the Sims' blade. Dr. G. S. Winston has still further modified this by making the flanges, screw, and button detachable. Removing these we have a Sims' speculum. Attaching them, and unscrewing the handle, we have left Nott's-Cusco's speculum. The instrument thus devised seems to me perfect in its economy and application.

149 West Twenty-third Street.

UTERINE LEECH AND ASPIRATOR.

By WILLIAM W. REESE, M.D.,

Brooklyn, N. Y.

The benefits resulting from depleting the neck of the uterus in most cases of engorgement or congestion, and the difficulty, delay, and uncleanliness common in the application of leeches, have led to the construction of the above-named instrument, which is found to be admirably adapted to the purposes, and free from the objections which obtain against leeches and other means heretofore employed, and which frequently induce physicians to forego the advantages of depletion, and to employ other modes of treatment less speedy and efficient, and usually more expensive to patients, because more tedious or protracted.

This instrument is a glass cylinder, 7½ inches long and about half an inch in diameter, with a well-fitting piston, through which is conducted a metallic rod with a spear-shaped point. This rod is surrounded at the outer end (handle) with a spiral spring which instantly draws it back, air-tight, into the piston after the cervix has been punctured or scarified with the point. The piston is then slowly withdrawn to any extent required, whilst the cylinder, which the practitioner keeps pressed up with one hand against the cervix, through a speculum retains the blood that follows. No wound is left like that produced by the bite of a leech, nor is any bleeding likely to continue after the withdrawal of the speculum.

A, on the figure, propels the point. *a* is a screw-cap that regulates the cutting distance by lengthening or shortening the spiral wire *B*, according to the wish of the operator. *b* is cap of the piston-rod, and *C* the cap of the cylinder. All of these caps are readily removed for cleaning any part of the instrument. The piston is graduated, in order that the quantity of blood drawn may be known without removing the cylinder.

This little instrument can be used with the same facility as an aspirator for small abscesses near the uterus, in suppuration of the tonsils, etc.

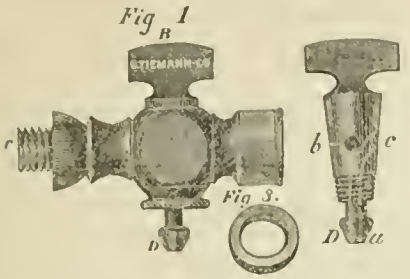
A NEW THREE-WAY STOPCOCK.

H. T. HANKS, M.D.,

New York.

The stopcock is made of hard rubber to fit any of the 4, 8 or 12 oz. Goodyear syringes. By its use the syringe is made double action, and is available as such, and for an aspirator and stomach pump. It consists of three parts, and is represented complete in

Fig. 1. The cut on the right, which should have been marked Fig. 2, represents the turn-cock. Fig. 3, the nut which holds the turn-cock *in situ*.



In using the instrument the end *C* should be fastened to the syringe, while to the opposite end, which should be marked *E*, may be attached either of the three nozzles in general use, and a rubber tube fitted to the end *D* of the turn-cock. If the instrument is to be used as a stomach pump, a suitable tube must be fastened to the end of the nozzle. If used as an aspirator, the usual rubber tubing and needle must be attached to the nozzle.

The principle of the action is at once understood by looking at the separate cut of the turn-cock. The dotted lines indicate the direction and position of a passage up through the turn-cock, from the hole *c* to the hole *a* in the end *D*. Through this curved passage fluids may be drawn in or out; or by turning the turn-cock one-quarter round fluids may be forced in or out through the hole *b*, which passes directly through the turn-cock. The two passages have no connection, and by proper management of the turn-cock may be used alternately.

I have used this instrument as aspirator and double action syringe for nearly two years.

Aug. 30, 1876.

A NEW VAGINAL DOUCHE.

By FRANK P. FOSTER, M.D.

The instrument shown in the accompanying cut is constructed as follows: a Politzer's bag (the nozzle having been removed) is inverted or squeezed in upon itself into the shape of a cup, which shape it is made to retain by means of two flanged tubes, one of which (with the flange inside the cup) screws into the other. To the outer flanged tube is attached a Davidson's syringe, furnished with a clip for securing the suction-tube to the edge of the vessel which contains the injection. To the inner flanged tube is attached, by means of a short piece of flexible rubber tubing, the nozzle of the instrument, which is a U-shaped tube of hard rubber, having an aperture near the bend and looking towards the opposite arm of the tube. An outflow-pipe is attached to the lower part of the soft rubber cup.

The particular object of the instrument is to enable a large vaginal injection to be administered without soiling the bed. The patient lying on her back, with the hips somewhat raised by means of a pad or hard cushion, the vessel holding the injection is placed in a chair or on a table by the side of the bed. The suction-pipe of the syringe having been made fast to the vessel by means of the clip, a few syringefuls of the fluid are first passed through the instrument, in order to expel the contained air. The nozzle is then introduced into the vagina, when the cup will be found to cover the vulva. The lower part of the cup is to be pressed gently, but firmly and evenly, against the perinæum, but *the upper edge of the cup should not be in contact with the patient's person*. The injection is now to be commenced by working the syringe in the ordinary way, and it may be kept up *ad libitum*, as the outflow-pipe conducts the fluid from the vagina into a vessel placed on the floor by the side of the bed for the purpose. Care should be taken that *every part* of the outflow-pipe shall be on a lower level than the lower portion of the rubber cup, and that it is not pressed upon anywhere or bent at too sharp an angle; otherwise there is danger that the fluid will overflow the

top of the cup and soil the bed. If a syphon action is preferred, it is only necessary to elevate the vessel containing the injection above the level of the vulva, when, after once starting the stream, it will be found to continue without the necessity of working the syringe.

The advantages claimed for this instrument are as follows:

(1.) It is cheap and simple, and easily worked by a nurse or by the patient herself, avoiding the unpleasantness of a bed-pan.

(2.) The injection cannot enter the uterus.

(3.) There can be no injurious distention of the vagina, as the double nozzle maintains constant patency of the vaginal orifice.

(4.) Its use does not give rise to pain, even immediately after confinement or when the parts are lacerated or inflamed.

(5.) On account of the flexible attachment of the nozzle to the cup, the instrument is perfectly efficient in cases of ruptured perinæum, even if the laceration extend into the rectum; but in that case the lower border of the cup must be held behind the anus.

I am indebted to Dr. Emmet for valuable suggestions in regard to the construction of the nozzle. As a matter of course, nozzles of various lengths, or specially fashioned in other respects, may be used to meet the requirements of particular cases.

The instrument is made by Mr. Ford, and is furnished by Messrs. Caswell, Hazard & Co.

Complete with Davidson syringe $6.50
Douche alone with three feet tubing 4.00

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from August 27th to Sept. 2d, 1876.

SMITH, J. R., Surgeon, and WOODWARD, J. J., Surgeon, designated to represent the Medical Corps of the Army at the International Medical Congress, to meet at Philadelphia on Sept. 4th. S. O. 176, A. G. O., Aug. 25, 1876.

STERNBERG, G. M., Surgeon. Assigned to duty at Fort Townsend, W. T., as post surgeon. S. O. 169, Dept. of the Columbia, Aug. 17, 1876.

GIRARD, J. B., Asst. Surgeon. Assigned to duty as post surgeon at Fort Wayne, Mich. S. O. 171, Mil. Div. of the Atlantic, Aug. 31, 1876.

By S. O. 178, A. G. O., Aug. 28, 1876, the following changes are made:

RANDOLPH, J. F., Surgeon. Relieved from duty in Dept. of the Platte, ordered to Philadelphia, Pa., and thence report by letter to the Surgeon-General.

The following officers are relieved from duty in the Department they are now serving, ordered before the Army Medical Board, New York City, for examination for promotion, and on its completion report by letter to the Surgeon-General:

DE GRAW, C. S., Asst. Surgeon, Dept. of Texas.
GARDNER, W. H., " " " the Missouri.
JESSOP, S. S., " " " " "
MILLER, G. McC., " " " Arizona.
MOFFATT, P., " " " the Missouri.

TREMAINE, W. S., Asst. Surgeon. Ordered before the Army Medical Board for examination for promotion, and on its completion return to his station.

HARVEY, P. F., Asst. Surgeon. To report to the Commanding General Dept. of Dakota for assignment to duty.

MCELDERRY, H., Asst. Surgeon. On expiration of his leave of absence assigned to duty at Fort Monroe, Va.

GIRARD, J. B., Asst. Surgeon. On expiration of his leave of absence to report to the Commanding General Div. of the Atlantic for assignment.

JACKSON, D., Asst. Surgeon. Relieved from duty in Dept. of Texas and ordered to Mil. Div. of the Atlantic.

The following named Assistant Surgeons, recently appointed, will report for duty or assignment as follows:

GARDNER, EDWIN F., to report to commanding officer Willet's Point, N. G. H., for temporary duty.

CORBUSIER, WM. H., by letter to Commanding General Dept. of the South.

BUELL, J. W., to accompany first detachment of recruits to Dept. of Texas, and on arrival, report by letter to the Department Commander for assignment.

SHUFELDT, ROBT. W., to Commanding Officer Fort McHenry, Md., for temporary duty.

APPEL, D. M., to Commanding General Dept. of the Missouri, for assignment to duty.

ANDREWS, W. C. C., to Superintendent Mounted Rec. Service, for temporary duty at St. Louis Barracks, Mo.

CUNNINGHAM, THOS. A., by letter to Commanding General Dept. of Dakota, for assignment.

BURTON, H. G., in person to Commanding officer Dept. of Arizona, for assignment.

AMERICAN GYNECOLOGICAL SOCIETY.—The first annual meeting of this society will be held in the Academy of Medicine, 12 West 31st street, New York, on September 13th, 14th, and 15th, 1876.

September 13.—Morning session at 10 o'clock. Papers: 1. Incision of the Cervix Uteri, by Dr. T. A. Emmet; Discussions by Drs. J. M. Sims, E. R. Peaslee, T. G. Thomas, and others; 2. Cicatrices of the Cervix Uteri, by Dr. A. J. C. Skene; 3. Report of a Case of Abdominal Pregnancy treated by Gastrotomy, by Dr. T. G. Thomas. Afternoon session at 3 o'clock. 4. Battey's Operation for Extirpation of the Ovaries, by Dr. R. Battey; 5. A Paper sent by Dr. J. Matthews Duncan, of Edinburgh; 6. Viburnum Prunifolium: its Uses in the Treatment of the Diseases of Women, by Dr. E. W. Jenks; 7. A Case of Abnormal Menstruation, by Dr. T. Parvin.

September 14.—Morning session at 10 o'clock. 8. Annual Address of the President; 9. A Paper by Dr. Robert Barnes, of London; 10. Spontaneous and Artificial Disintegration of Fibrous Tumors of the Uterus, by Dr. W. H. Byford; 11. Pneumatic Self-Replacement in Dislocations of the Gravid and Non-gravid Uterus, by Dr. H. F. Campbell. Afternoon session: 12. Latent Gonorrhœa, especially with regard to its Influence on Fertility in Women, by Dr. E. Noeggerath; 13. Hydrate of Chloral in Midwifery Practice, by Dr. W. L. Richardson; 14. A Case of Labor complicated with four large Uterine Fibroids and Placenta Prævia, by Dr. J. R. Chadwick.

September 15.—Business meeting at 9 A.M., with closed doors. Morning session at 10 o'clock: 15. What is the Best Treatment for Acute Lacerations of the Female Perineum, and for Lesions of the Recto-Vaginal Septum? by Dr. W. Goodell; 16. Paper sent by Mr. Lawson Tait, of Birmingham, England; 17. Cases of Cystic Tumors of the Pelvis, by Dr. G. H. Bixby. Afternoon session: 18. Masturbation in Women, with a Report of Seventeen Cases treated with Bromide of Potash, by Dr. J. R. Chadwick; 19. What is the History of Calculi formed in the Bladder after Operations for Vesico-Vaginal Fistulæ? by Dr. H. F. Campbell. Adjournment at 5 P.M.

INTERNATIONAL MEDICAL CONGRESS.—We shall endeavor to commence our report in the next number.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

GEORGE F. SHRADY, A.M., M.D., Editor.

PUBLISHED BY

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, September 16, 1876.

INTERNATIONAL MEDICAL CONGRESS.

THE International Medical Congress at Philadelphia has proved, as we expected, a success. A large number of delegates were present, and their deliberations were of a character to do honor to the occasion. International Congresses are as yet in their infancy of usefulness, and it must be no small congratulation for such as are interested in the discussion of general questions relating to medical progress, that some effective step is taken in the required direction to show that each meeting is an improvement upon its predecessor. The meeting in Philadelphia can safely be said to take up the spirit of the former Congress and propagate it further on towards the realization of tangible and practical results. Differing somewhat from other gatherings of its sort in being the occasion of a centennial jubilee, there was, however, a becoming diguity in all the proceedings which referred to such an occasion. The addresses were, without exception, models of their sort. The historical element of which they partook was eminently in proper keeping with the spirit of the meeting, and reflected great credit upon the good taste and discrimination of the orators. The address of welcome was singularly appropriate, foreshadowing, as it did, the work expected to be accomplished by the Congress, and giving the direction of effort that wide range which was in keeping with the character and extent of the representation.

We are gratified to note that the suggestions concerning uniformity in medical observation, as offered by the President, were so intelligently acted upon by the meeting. The endorsement of the principle involved in this question was all that could be expected of the Congress under the circumstances, and in so far some real progress has been made in the right direction. The discussion of the subject is thus encouraged, and by and by the practical results will show themselves in the shape of some well-digested and practical plans. The time will yet come when there will be but one medical language over the entire world, but our enthusiasm for its hasty accomplishment must be tempered with the patient investigation of those means which will best insure the end.

There were other general questions which might have come up for discussion, but, as we before remarked, Medical Congresses are as yet mere experiments, and we must for the present be satisfied with a promising beginning. The other general questions, the discussion of which would belong to such a representative body of medical men, have not perhaps been sufficiently discussed to warrant attention as yet, but we are convinced that the professional mind is getting ready to attack them, and that before long the legitimate work of an International Medical Congress will be as systematically mapped out as that of any other smaller society. The material for the work is at hand; all we have to do is to learn to use it.

The large attendance at the meeting and the widespread character of the representatives showed the general interest manifested in such gatherings. The success of the meeting at Philadelphia will add not a little to this interest, and we hope to see it stimulated still more at the meeting in Geneva.

The arrangements in Philadelphia were carried out in a manner that reflected credit upon the committee having it in charge. Everything was calculated for, and, despite the multitude of interests to be consulted, as far as we can learn every one was satisfied with the character and scope of the programme. If any suggestion for improvement in management might be made, it would refer to the more systematic apportionment of time to the different sections. It would seem that, with the time devoted to the sections, some arrangement might be made to give some longer sessions than others in proportion to the number and extent of the subjects to be discussed, and as far as possible to have the more important sections meet at different hours. As it was, the uniformity of the hour of commencement caused all the sections to be in full operation at once, and those interested in the discussion of many subjects were necessarily restricted to one. Everything considered, however, it was probably the best that could be done under the circumstances, and, far from finding fault, it is a matter of surprise that the complicated machinery moved so harmoniously, and so well met the general expectations of the delegates. The election of the officers will meet with very general satisfaction. The honor of president was worthily conferred, and met the expectations of every delegate present. The offices of vice-president were very judiciously distributed, and infused a truly international element into the election.

The Congress was distinctive in its character in many respects. Its very organization, or rather mode of constitution, elevated it above every other national society or

association in its capacity for usefulness. It was composed of delegates from national and State societies only, so far as the United States were concerned, and its representatives from abroad were men of culture and refinement. None of the quarrels of minor societies could find a place in its deliberations. It was thoroughly cosmopolitan in its objects, and though the transatlantic world sent comparatively few of its medical men to participate in it, the score or more who had the courage to cross the ocean gave a thoroughly international character to the Congress, and an additional interest to the discussions. Our neighbors of the Dominion were there in respectable numbers, and seemed gratified with the prospect held out to them, by the recent international conference in Philadelphia of committees of the Canadian and American Medical Associations, of annexation of those two bodies, and annual interchange of friendly greetings.

We invite special attention to the report, which we publish elsewhere, of the proceedings of the Congress. It has been our object to give our readers a faithful record of an event in which so many thousands of the profession are interested; and we have not hesitated, therefore, to allot to it a liberal share of space in our columns. The occasion is a very unusual one, and the instruction to be derived from a perusal of the abstract of the proceedings, extraordinary in amount and in degree. The Congress threw open its doors widely to the public and to the public press for four days of its sessions; but on the fifth day adopted a very unwise and unnecessary resolution in regard to the reporting of its proceedings, which to us came in the light of an *ex post facto* law, after the reports of the first three or four days were already in type. The resolution, which will be found in another column, was offered by one of the most respected members of the Congress, at the suggestion of another member, without, we presume, due consideration of all its bearings. Its object was apparently to prohibit all publications in medical journals of papers and addresses "in abstract or otherwise," plausibly because they might interfere with the sale of the volume of Transactions. Whatever the motive, personal "or otherwise," for the introduction of such a resolution, or whose fertile brain originated it, or whether some medical journal of feeble enterprise suggested it as an apology for failure to convey to its readers a satisfactory record of the Congress; it seemed almost an act of self-stultification on the part of that learned body, after hundreds of copies of the outlines, as elaborate as abstracts, of all the important papers had been published and liberally distributed by the Centennial Medical Commission, and after the reporters of the public press had been allowed every privilege at the hands of the Congress, with full license, if they so desired it, to publish phonographic reports of every paper read before the Congress, or any sectional portion of it. We shall closely scan the columns of our contemporaries, and if we find in any of them a meagre report combined with a virtuous diatribe against those who have not obeyed the unreasonable behests of the Congress, we shall be able to draw our own inferences. Without discussing the rights of the public press, medical included, on all public occasions in which the doors are thrown widely open to every comer and to every listener, we feel assured that a general notice of the Congress, which excites the interest of the profession at large by such abstracts as those we publish to-day, will stimulate a widespread curiosity to see and to possess the complete Transactions when the volume issues from the hands of the Committee of Publication. We do not envy them the task they have before them, although the material upon which they have to work is of an unusual order of merit.

Progress of Medical Science.

Easy Method of Extracting a Broken Catheter from the Urethra.—Dr. Young was recently called to a patient about eighty years of age, who was suffering from retention of urine, caused by the breaking in the urethra of a No. 8 silver catheter which he had been in the habit of using. The point of breakage was beyond the beginning of the curve, and it presented two sharp pointed spicula, three-eighths of an inch long. On external examination the urethra was tender; the broken portion of the catheter lay about seven inches from the meatus, and was movable only in the direction of the bladder. Dr. Young took the eyes off a No. 11 catheter and passed it down to and over about an inch of the broken end, when, on making an angle with No. 11, No. 8 became locked and was easily withdrawn. This method of extraction may be employed, with modifications, in removing other foreign bodies. On fixing the object to be removed, by external pressure, the tube slides easily over it, and it can be extracted by manipulation without wounding the mucous membrane.—*British Medical Journal.*

Subcutaneous Division of the Femur.—On May 16, 1876, Mr. Richard Davy divided the femur subcutaneously (after Langenbeck's method on the tibia) for bony anchylosis of the ileo-femoral joint in a boy aged fourteen. The right femur was flexed on the abdomen at an angle of 90°, the angle being measured at the anterior superior spine of the ilium; the femur was also adducted so that the legs crossed; the genitals were partially eclipsed, and the right inguinal fold deepened. A small cut was made down to the anterior plane of the femur, immediately below the trochanters; the commencing shaft was drilled through and through this opening, a keyhole saw almost effected division of the femur by right and left movements; complete division was caused by periosteal fracture. The limb was at once abducted, straightened, and placed symmetrically; correct position was maintained by splint and sand bags. The young fellow progresses without any unfavorable symptom, and bony union in the re-formed position is being accomplished by nature.—*British Medical Journal.*

Reports of Societies.

PROCEEDINGS OF THE INTERNATIONAL MEDICAL CONGRESS.

This body, composed of delegates from foreign medical societies, and from national and State medical organizations of this country, together with distinguished invited guests from abroad, met at Philadelphia, Monday, September 4th. The general sessions were held each morning of the week to Saturday, September 9th, inclusive. Five afternoons were devoted to the meetings of sections, of which there were nine: Medicine, Biology, Surgery, Dermatology and Syphilology, Obstetrics, Ophthalmology, Otology, Sanitary Science, and Mental Diseases. About four hundred and fifty delegates and invited members were present.

ADDRESS OF WELCOME.

The session was opened by Professor Samuel D. Gross, M.D., D.C.L. Oxon., President of the Centennial Medical Commission. After prayer by the Right Rev. William Bacon Stevens, Bishop of Pennsylvania, Prof. Gross delivered the address of welcome to the Congress. He greeted them in the name of the entire American medical profession. The occasion, he stated, was an unusual one. Everything had been fully discussed, and time and labor thoughtfully and earnestly bestowed by the Commission, to perfect the organization of the Congress. It was at all times a gratification to welcome friends, but the feeling was vastly heightened by the fact that so many distant parts of the world were represented—Europe, the far East, Japan, China, etc. So far as known, every prominent medical society, and every distinguished medical man had received invitations. It was a glorious spectacle to see men laying aside their ordinary pursuits, crossing vast continents and perilous seas, to unite with us in celebrating our first medical centennial, and interchanging views and observations, laying the results upon a common altar, for the common good. No other congress ever had such a cosmopolitan outlook. It would exhibit what America had accomplished in a century in scientific work. Time was when we had no American medical literature or medical science; we were dependent on Europe until after this century opened. The addresses to be delivered by some of the best medical men of the country would show the completeness and rapidity of our progress. The period of medical provincialism has long since passed.

The speaker then alluded to the desirability of establishing a uniformity of nomenclature, weights, measures, and records of disease; to the modern improvements in the use of the microscope, chemical analysis, clinical observation, and experiments on inferior animals. Much could be done by this Congress for the advancement of medical science and international unity, strengthening the bonds and securing the co-operation of its votaries in various portions of the globe. It was well for men of different nationalities to come together to look each other in the face, and see what they have done to further the interests of scientific progress and to lighten the burden of human suffering, to interchange kindly feelings, to form new friendships, and cement old ties. Such international reunions should be more frequent and more numerously attended. After incidentally alluding to the Exposition, and suggesting that the Congress should perfect its organization by the election of its own officers, Prof. Gross declared the sessions formally opened.

COMMITTEE OF NOMINATIONS.

The President then announced the following Committee of Nominations, named by the Commission, which was, on motion, confirmed by the Congress: Mr. William Adams, London; Prof. Engelsted, of Copenhagen; Prof. Hüter, of Greifswald; Prof. Rudnew, of St. Petersburg; Dr. J. A. Grant, of Ottawa, Canada; Dr. Henry I. Bowditch, of Boston; Prof. L. A. Dugas, of Augusta, Georgia; Prof. J. T. Hodgen, of St. Louis; Prof. Christopher Johnston, of Baltimore; Prof. Austin Flint, Sr., of New York; Dr. W. S. W. Ruschenberger, U. S. Navy; Dr. Joseph R. Smith, U. S. Army; Dr. Edwin M. Snow, of Providence, R. I.

ADDRESS ON MEDICINE.

Professor Austin Flint, of New York, then delivered the Address on Medicine. After a few introductory remarks, he alluded to the potential agency exercised by the medical men of the country during and after the Revolutionary period; to the germination of medical literature at that time, and the foreshadowing of medical schools. He next referred to the practice of inoculation, and the pulpit denunciation of its sinfulness. Medical progress was signal after the war of independence. Two rival schools were soon in existence, and some interesting facts were detailed by the writer, of pecuniary contributions to schools and to the interests of medicine, the foundation of prizes at Harvard, etc. The medical schools of Philadelphia were modeled after that of Edinburgh. Cullenism prevailed, but was not long maintained, although it regulated practice, especially in the hospitals. After speaking more particularly of the physicians and surgeons of Philadelphia at that date, he alluded to the good work done in the provincial schools, which often supplied professors to the larger institutions of learning. Subsequent increase of the schools was not in proportion to the population, the number being scarcely greater now than in the early part of this century.

The part early taken by medical journals in contributions to medical literature, the characteristics and effects of Dr. Benjamin Rush's writings, the attachment of medical men of this country to the medical literature of Great Britain, even after the war of 1812, and the formation of medical societies in the early part of the century, were all referred to. He then alluded to the introduction of vaccination and the opposition it encountered. In 1814 the plans for the first American National Pharmacopœia, that of 1820, were laid. The next quarter of the century saw the discovery of ether as an anæsthetic; and the improvement of histological research, the translation of Bichat's work paving the way. Dr. Gross, early in his medical career, was identified by his writings with the study of pathological anatomy in this country; so also Dr. J. B. S. Jackson. Auscultation and percussion in this quarter also came into general use in the United States through the translation of Laennec and writings of James Jackson, Holmes, and others. Its literature, and that of the physical exploration of the heart, were sketched by the speaker.

Bright's history of cases in 1828, introduced to general attention here, was followed by great progress in this form of pathology ever since. In 1828 the *American Journal of the Medical Sciences* was first published. Dr. Flint then alluded to the discoveries

in the nervous system in this country, and the papers written upon them; to Beaumont's researches on digestion in the case of gastric fistula of Alexis St. Martin; to the views and literature of Broussaism, which fell and left no "ism" as its successor; to John Esten Cook and the heroic calomel treatment of his day; to the views of Louis on phthisis and yellow fever; to the self-limited nature of diseases, as advocated by Dr. Jacob Bigelow in 1835; to the decay of polypharmacy and the progress of expectant medicine. The *United States Dispensatory* was published in 1833; the American Medical Association was founded in 1847.

The speaker then detailed the chief works on practical medicine during the second quarter of the century, with sketches of the labors of Dr. Nathan Smith, James Jackson, J. K. Mitchell, Drake, and others. The general introduction into this country of quinine was referred to, and also the contributions to the literature of yellow fever, croup, infantile therapeutics, affections of the brain, nervous system, air-passages, etc. The use of topical applications to the larynx, and of opium, the early employment of suction from the pleural cavity, now called aspiration, all belong to the history of American medicine. He then gave a brief list of some of the authors of this quarter, and the names of those who have died.

The third, or last quarter of the century is familiar to most of us. The great characteristic of progress in the United States at this epoch is in histology. Its influence on prophylaxis and practice were alluded to. After referring to the advantages of an international copyright for our own protection, and to the advanced position of American medical literature, and its recognition abroad, he declared that the chief characteristic of our medical schools, in spite of all cavil, was practical teaching. In conclusion, he dwelt on the good influences of the Code of Ethics of the American Medical Association, and to the elevated social position and public influence of the medical profession in this country.

Dr. Gross called attention to the fact that the speaker had modestly omitted all mention of his own (Dr. F.'s) contributions to American medical literature.

On motion of Dr. J. P. White, the thanks of the Congress were tendered to both gentlemen, and their addresses referred to the Committee of Publication.

OFFICERS OF THE CONGRESS.

The Committee of Nominations then reported the names of the following gentlemen for permanent officers of the Congress, all of whom were elected:

President: Professor Samuel D. Gross.

Vice-Presidents: Prof. Paul F. Eve, of Tennessee; Mr. Joliffe Tuffnell, of Ireland; Drs. W. L. Atlee, of Pennsylvania; C. Lange, of Denmark; J. B. Johnson, of Missouri; F. Semeleder, of Austria; Dr. Hunter McGuire, of Virginia; Dr. Johan Hjort, of Norway; Dr. T. G. Richardson, of Louisiana; Dr. Wm. H. Hingston, of Canada; Dr. J. P. White, of New York; Dr. H. Miyake, of Japan; Prof. Nathan R. Smith, of Maryland; Prof. Rudnew, of Russia; Dr. Joseph M. Toner, of Washington; Prof. Hueter, of Pomerania; Dr. G. L. Collins, of Rhode Island; Dr. R. F. Hudson, of Australia; Dr. Henry Gibbons, of California; Dr. P. Debasieux, of Belgium; Dr. N. S. Davis, of Illinois; Mr. William Adams, of England; Dr. L. A. Dugas, of Georgia; Prof. A. R. Simpson, of Scotland; Dr. J. K. Bartlett, of Wisconsin.

Honorary Vice-Presidents: Surgeon-General J. K. Barnes, U. S. Army; Surgeon-General Joseph Beale, U. S. Navy.

Treasurer: Dr. Caspar Wister, of Pennsylvania.

Secretary General: Dr. I. Minis Hays, of Pennsylvania.

Secretaries of Meetings: Drs. W. B. Atkinson, Richard J. Dunglison, R. A. Cleemann, W. W. Keen, R. M. Bertolet.

OFFICERS OF SECTIONS.

Medicine. *Chairman.*—Alfred Stillé, M.D., Philadelphia; *Vice-Chairmen.*—R. P. Howard, M.D., Canada; J. J. Woodward, M.D., U. S. A.; *Secretary.*—J. Ewing Mears, M.D., Philadelphia.

Biology. *Chairman.*—John C. Dalton, M.D., New York; *Vice-Chairmen.*—Austin Flint, Jr., M.D., New York; F. W. Campbell, M.D., Canada; *Secretary.*—James Tyson, M.D., Philadelphia.

Surgery. *Chairman.*—Prof. Joseph Lister, Edinburgh; *Vice-Chairmen.*—J. A. Grant, M.D., Canada; John Ashhurst, Jr., M.D., Philadelphia; *Secretary.*—John H. Packard, M.D., Philadelphia.

Dermatology and Syphilology. *Chairman.*—James C. White, M.D., Boston; *Vice-Chairmen.*—S. Engelsted, M.D., Copenhagen; Edward Shippen, M.D., U. S. N.; *Secretary.*—A. Van Harlingen, M.D., Philadelphia.

Obstetrics. *Chairman.*—Robert Barnes, M.D., London; *Vice-Chairmen.*—Prof. Alex. R. Simpson, Edinburgh; W. H. Byford, M.D., Illinois; *Secretary.*—Wm. Goodell, M.D., Philadelphia.

Ophthalmology. *Chairman.*—R. Brudenell Carter, F.R.C.S., London; *Vice-Chairmen.*—Wm. Thomson, M.D., Philadelphia; Henry W. Williams, M.D., Boston; *Secretary.*—John Green, M.D., St. Louis.

Otology. *Chairman.*—Clarence J. Blake, M.D., Boston; *Vice-Chairman.*—A. H. Buck, M.D., New York; *Secretary.*—H. N. Spencer, M.D., St. Louis.

Sanitary Science. *Chairman.*—Stephen Smith, M.D., New York; *Vice-Chairman.*—J. S. Billings, M.D., U. S. A.; *Secretary.*—E. M. Hunt, M.D., New Jersey.

Mental Diseases. *Chairman.*—John P. Gray, M.D., New York; *Vice-Chairmen.*—E. Grissom, M.D., North Carolina; I. Ray, M.D., Philadelphia; *Secretary.*—Walter Kempster, M.D., Wisconsin.

COMMITTEE ON PUBLICATION, WITH POWER TO SELECT CHAIRMAN AND EDITOR.

John Ashhurst, Jr., M.D., Philadelphia; R. J. Dunglison, M.D., Philadelphia; Wm. Goodell, M.D., Philadelphia; James H. Hutchinson, M.D., Philadelphia; Caspar Wister, M.D., Philadelphia.

The Congress then adjourned.

PUBLIC RECEPTION BY THE PROFESSION.

In the evening a public reception was given the Congress by the medical profession of Philadelphia at Judges' Hall, Centennial Grounds. About six hundred persons were present. The evening's entertainment was concluded with a collation at the Lafayette Restaurant in the same grounds.

DAILY REPORTS FROM THE SECTIONS.

On Tuesday, at ten o'clock, after the reading of the minutes, the reports of Sections were called for, and the conclusions arrived at by them submitted to the Congress. After the adoption of the conclusions voted on by the Sections of Dermatology, Sanitary Science, and Otology, and their reference to the Committee of Publication, Dr. T. G. Richardson, of Louisiana, moved that the Congress is not responsible for these conclusions, all responsibility being with the Sections themselves.

Dr. Hays stated that previous International Congresses abroad had voted to sustain or reject the conclusions adopted by the Sections.

Dr. Davis, of Chicago, was of the view that these reports should only be accepted and referred to the Committee of Publication; and an amendment to that effect was appended to the previous motion, and with it adopted.

On motion of Dr. Brodie, of Michigan, the action of the Congress in confirming the conclusions reported by the Sections was reconsidered, and their reports accepted and referred.

The other sections having reported, various invitations were read by the Secretary; also greetings from St. Petersburg Medical Society and the University of Christiania, Norway.

THE NATIONAL MEDICAL LIBRARY.

Resolutions complimentary to the Surgeon-General and his assistants, and recommending action on the part of this Congress in a direct appeal to the National Congress for encouragement of their labors, and specially in the publication of the valuable catalogue of the National Medical Library, were offered by Prof. Flint, and adopted.

ADDRESS ON HYGIENE AND PREVENTIVE MEDICINE.

The hour of eleven arriving, Dr. H. I. Bowditch then read the address on Hygiene and Preventive Medicine, Vice-President Eve in the chair. He divided the century into three irregular periods: 1776 to 1832, the age of theory merely, and of medical system-making; 1832 to 1869, that of strict observation and accurate recording of facts, but of great skepticism; 1869 to 1876, the age of progress in State preventive medicine. In the first epoch, Boerhaave, Cullen, and Rush flourished. He gave a sketch of Rush, and of the rise and fall of Broussaism.

The second epoch was that of Louis and his disciples. The part taken by Jacob Bigelow, Elisha Bartlett, and John Forbes was referred to. The medical profession did not take much interest in State preventive medicine; progress in it was due more to the laity than the profession, especially to Lemuel Shattuck, of Boston, and Edwin Chadwick, of England. The Massachusetts Sanitary Commission Report in 1825 fell flat, but its recommendations were adopted in 1869. The speaker then alluded to a variety of subjects—the labors of Europeans, of sanitary journals and writers, especially in England, with her trained inspectors, the United States Army and Navy service, the Surgeon-General's library, the various Sanitary Commissions of the late war, the quarantine conventions that met before the war, the effect of the war in disciplining the surgeons to systematic prevention of disease by the enforcement of sanitary measures, the establishment of the American Public Health Association in 1872, and of the Social Science Association, the efforts of the American Medical Association, etc.

PRESENT SANITARY CONDITION OF THE UNITED STATES.

To determine the present condition of sanitary progress, Dr. Bowditch sent inquiries to one hundred and sixty-seven men of intelligence, living in thirty-eight States and nine Territories, covering twenty-five degrees of latitude and forth-seven degrees of longitude, and occupying every phase of climate. Some of these replies, arranged according to States, may be briefly given:

1. Does the State duly appreciate and care for the health of the people? 34 nays, 8 yeas.

2. Is the State willing to spend money to establish a State Board for various beneficent purposes cited? 36 nays, 10 yeas. In some States these boards are established, but no money is appropriated.

3. Is the State willing to spend money for investigation of preventable causes of disease? 30 nays, 12 yeas. In Massachusetts ten thousand dollars were appropriated last year to check the pollution of streams.

4. Is the State willing to spend money for prevention of noxious trades? 26 nays, 14 yeas. Brighton, Mass., once the centre of numerous offensive slaughter-houses, is now a beautiful and fashionable spot, since these were got rid of.

5. Is the State willing to take measures to prevent the adulteration of food? 23 nays, 16 yeas.

6. Has the State any Board of Health? has it a properly organized set of correspondents? No perfect set exists in any State. There are twelve State Boards of Health altogether.

7. Has the State a law for the registration of vital statistics, for irrigation, prevention of disease, sanitary survey, etc.? 40 nays, no yeas.

8. Has it a law for the registration of marriages, deaths, etc.? 16 nays, 20 yeas; eighteen of the latter being qualified, stating that the law is imperfect, a dead letter, carried out in the large cities only, etc.

9. Has it any law in regard to drainage of lands? 24 nays, 7 yeas; but in the latter the drainage is for agricultural, not sanitary, purposes.

10. Has it a law for introduction of water into cities? 23 nays, 14 yeas; but there is no law to insure the purity of the water.

11. Has it any law in regard to contagious diseases? 16 nays, 21 yeas. There should be a national law for enforcement of vaccination, and every foreign nation should adopt it. An international code of health must come sooner or later.

12. Has it taken any action in regard to the use of well-water, etc.? In one hundred and forty-eight towns eighty-two wells were reported, the water in the rest being derived from rivers. Two-thirds of the people of the United States are living in total disregard of all knowledge or interest in the kind of water they are using.

13. Has it any regulation for the disposal of sewage? Only one-fifth have any definite idea that any action is necessary.

14. Has the State, county, or city published health reports? Three-fourths of the States ignore the matter.

15. Is there any known law of development or partial development of disease to give as a legacy to the next century as a preventive? 39 nays and 6 yeas. Special points are mentioned as to the development of zymotic diseases, modes of prevention, etc.

Our present duty is organization. Two hundred thousand persons are annually slaughtered in the States by preventable diseases. The speaker concluded by expressing great hopes of the future, and of the coming century in the increased health, and the lengthening of human life it was sure to bring with it.

ADDRESS ON MEDICAL CHEMISTRY AND TOXICOLOGY.

Prof. T. G. Wormley, of Ohio, then read the address on Medical Chemistry and Toxicology. He alluded to the prominent chemists of the century, to the relations between pharmacists and physicians; to the early foundation of medical schools in Philadelphia, in which chemistry was taught, as by Dr. Rush and by Dr. Dexter at Harvard; to the gradual but slow

advance made in chemical research at that time; to the discoveries of Drs. Robert Hare, J. Redmond Coxe, and others; the establishment of the Philadelphia school of Pharmacy in 1821, and the various changes in the professorships of that institution; to the establishment of the *American Journal of Pharmacy* in 1825, and of the second school in New York in 1829, etc.

Of the American chemical contributions to medicine, he cited the investigations of the properties of indigenous plants, as sanguinaria, and the discovery of its alkaloid, identical with that afterwards discovered in chelidonium majus. Lobelia and veratrum viride, and their alkaloids, were also referred to, with a historical sketch of the investigations into all these subjects; also the history of the manufacture and introduction into practice of chloroform, or spirits of chloric ether, as it was then called. Allusion was made to the employment and preparation of nitrous oxide, and to the discovery of the anæsthetic effects of ether, chloroform, and nitrous oxide; to Dr. Draper's investigations into urea; and those of Dr. Austin Flint, Jr., on cholesterine and stercorine.

Toxicology was then touched upon, arsenic being first mentioned, the fact being stated that in the early part of the century it was impossible to detect less than one grain of the substance. The names were given of various chemists who contributed to the subject of toxicology of arsenic at this and a somewhat later period, as Drs. Dana, J. K. Mitchell, Wm. R. Fisher, J. Lawrence Smith, Gardner, of Virginia, and J. C. Draper. Opium and strychnia have also been studied with valuable results by American chemists, so far as tests are concerned; so also digitaline, atropia, woorara, etc., as investigated by Hare, Percy, Hammond, S. W. Mitchell, James Blake, and others. The discoveries of morphia, and other alkaloid principles enabling the practitioner to prescribe medicines in concentrated forms, the processes of extracting the alkaloids, their solubility in ether, the study of crystalloids and colloids, the discovery of minute tests for strychnia and other alkaloids, of spectrum analysis with the spectroscope and microspectroscope,—all these points were dwelt upon in their relations to the study of toxicology in America. He also referred to the rapidity of action of poisons, as shown by Blake's experiments, and the conclusions derived from the Palmer poisoning case in England, in 1856; to the mode in which poisons destroy life, and to the slight physical and chemical changes in that fluid that result from their introduction. This valuable address concluded with allusions to the importance of a more general study of toxicology, and to the advantages to be derived from it.

DISTRIBUTION OF THE REPORT ON HYGIENE.

On Wednesday morning, President Gross in the Chair, on motion of Dr. John L. Atlee, the Secretary was instructed to send copies of Dr. Bowditch's address on Hygiene, when printed, to the Governors of the various States, for transmission to the Legislatures. The same action was, on motion of Dr. Trenholme, of Canada, authorized to be taken with the Dominion Government and with each province of the Dominion.

On motion of Dr. Traill Green, Dr. Wormley's address on Medical Chemistry, etc., was referred to the Committee of Publication, and the name of Dr. W.'s wife, who had prepared all the engravings of his work on Micro-Chemistry, enrolled among the members of the Congress.

The Secretary-General reported three hundred and eighty-two names on the Register; and read invitations from various sources, among others, from the National Temperance Association at New York, inviting the Congress to give a public declaration in regard to the effect of alcohol as a beverage and a medicine, and calling attention to its evil effects. This was received and laid on the table.

THE INTERNATIONAL CONGRESS OF 1877.

The Reports of Sections were then read, and the following resolutions, introduced from the Section on Medicine, adopted:

Resolved, That the International Medical Congress of 1876 recognize the advantages which would accrue from the introduction of a gradual uniformity in the multiple and heterogeneous elements of physic, as posology, nomenclatures, etc., and in the means and records of medical observation.

Resolved, That in consequence, this Congress authorizes the President to appoint delegates to the International Congress of 1877, with the special mission of presenting a schedule of the means of uniformity in physic actually applicable in all countries, and another of those which could soon be made acceptable by the profession at large.

Resolved, That the said delegates be advised to invite the co-operation of the men who have already worked for the same cause at the International or National Medical or Pharmaceutical Congresses of Paris, Vienna, St. Petersburg, and Brussels.

THE ADDRESS ON SURGERY.

Prof. Paul F. Eve, of the University of Nashville, then read the address on Surgery; Prof. Rudnew, of Russia, in the Chair.

The speaker alluded to the fact that the necessity of education abroad at first gave us no national medical characteristics. He then alluded to the various surgeons that had given America a reputation in this great field. He began with Physick, whose career he sketched, together with his improvements in surgical operations and appliances, as the tonsillotome, etc., the treatment of inflamed joints by perfect repose in coxalgia, spinal affections, etc. He mentioned a case of numerous calculi, one thousand in all, removed at one time by him from the same patient. He never spilt a drop of blood unnecessarily or wasted a word in his lectures.

He then sketched briefly the professional services of Physick's four contemporaries, Warren, Mott, Dudley, and Gibson, whose average age at death was eighty-three. Warren was the first to operate with a patient under the anæsthetic effects of ether. He himself contended that his tapping the pericardium in a case of dropsy was the first on record. He was the first to close fissure in the vault of the mouth. Valentine Mott was noted for the boldness of his operations; he was the first to ligate successfully the common iliac; the first to exsect entirely the clavicle, tying forty arteries in an operation lasting four hours; the first to exsect the entire inferior maxilla. He tied the carotid fifty-one times, and amputated about one thousand limbs. No surgeon, living or dead, ever performed so many great operations. He operated whenever there was the slightest prospect of benefiting his patient.

Dr. Benj. Winslow Dudley paid special attention to preparing his patient for operation by attention to his chylopoietic viscera, etc. He claimed to be the first to relieve intracranial aneurism by tying the carotid; he was a master of the bandage; a great lithotomist, although the statistics of his operations have been lost. Gibson was a splendid lecturer, and

illustrated his lectures with beautiful models; he first tied the iliac artery for gunshot wound in the streets of Baltimore, the patient living thirteen days. He twice performed the Cæsarian operation successfully on the same patient, Prof. Jos. Pancoast having had a similar experience.

Dr. Andrew Wood Smythe, of New Orleans, in 1864 tied the carotid and vertebral arteries, and the patient lived ten years, dying of a second operation on the mammary artery. The ligation of the vertebral artery has been done by several. Dr. Cogwell, of Hartford, in 1803 first tied the common carotid. Until Dr. Gross published this fact, Sir Astley Cooper had all the credit of it. Dr. Wm. T. Briggs, of Nashville, was the first to apply two ligatures to the internal carotid. Prof. Post, in 1817, first successfully tied the subclavian, others abroad having failed.

Dr. W. Stone first applied metallic ligatures to a wounded artery. Dr. S. W. Gross has shown the comparative innocuousness of applying ligatures to veins. The practice of ligation of vessels for the relief of gangrene is of American introduction. Arterial compression was long known in this country. The employment of the Hunterian method of ligation as a means of prevention, or for the relief of destructive inflammation, was proposed in the United States. Dr. Carnochan first ligated the femoral for elephantiasis, and afterwards, in the same case, the external iliac, successfully. Dr. Jonathan Knight was the first to treat popliteal aneurism successfully by digital compression.

The speaker then alluded to the successful methods of treatment proposed and employed by American surgeons in varicocele, affections of the bones and joints, etc., etc. Dr. Daniels, of Georgia, first introduced extension by weights and pulleys in fractures. A more detailed allusion was made also to the various modifications of fracture apparatus devised in this country, also to the efforts to overcome deformity in fractures, although, with most American surgeons, Dr. Eve believes that the os femoris, when fractured at certain points, cannot be extended to its full normal length and so maintained, without impairing its nutrition.

Manipulations for reduction of fractures by Dr. Wm. R. Reed is called by Mr. Spencer, the American or circumduction method. The discovery of the anæsthetic effect of ether in its relations to surgery was referred to, and also the important diagnostic sign described by Dr. L. A. Dugas, of Georgia, by which absolute distinction was readily made between fracture and dislocation at the shoulder. Allusion was also made to the various modifications of splints, to the services of Dr. J. Rhea Barton and J. Kearney Rodgers, in resection and exsection—the former, according to Erichsen, performing the first resection for bony anchylosis. Dr. Mussey, in 1837, performed excision of the whole scapula. Dr. Brainard, of Chicago, took the prize of the American Medical Association on the subject of perforation of the bones as a surgical expedient. Barton, Brainard, and Buck were the first satisfactorily to relieve osseous deformities. Various other cases of resection of special bones were referred to, the resection of a portion of the coccyx for neuralgia, Sayre's numerous cases of successful resection of the femur, the employment of tenotomy, etc.

Dr. Mott founded the first orthopædic hospital in this country. Dr. Sayre has done more work in this department than any other person. Reference was also made to the operations of Americans for contracted limbs, congenital deformities, operations for exsection of the kidneys and on the genito-urinary apparatus, on the air-passages, etc. Primary amputation at the hip-joint for wounds was first successful in 1806. Three or four successful cases are reported in the late war; previously in foreign wars all had failed. If not for the record of these successful cases, says von Langenbeck, the Prussian Surgeon-General, it is doubtful if the operation would not have been prohibited.

The use of silver wire by Sims in uterine surgery was also referred to. Numerous other operations, as detailed by Dr. Eve, shed lustre on American surgery. He then alluded to the contributions made by surgeons to medical literature; to the labors of the Surgeon-General of the Army and his assistants, and to the mortality of the medical officers of the army during the late civil war, as being greater in proportion than that of any other branch of the service. Seventeen thousand operations had been performed by them. He mentioned the foreign tributes to the labor of the medical service during the war, during which they said they did the work of a century.

THE ADDRESS ON MEDICAL BIOGRAPHY.

Dr. Joseph M. Toner, of Washington, D. C., then read the address on Medical Biography, Vice-President L. A. Dugas in the chair. He detailed the names and services of physicians distinguished during the century. The address was chiefly a compendious abstract of a voluminous paper, which will be published in the volume of Transactions, being full of biographical details that could not appropriately be read before the Congress. He divided the noted medical men into those of national, and those of local or State reputation merely, giving a hurried sketch of many of these, and selecting such only for special notice as were distinguished for high endowments, incessant application to study, etc., beginning with those of general professional reputation, Rush, Mott, Physick, the Warrens, Drake, Nathan Smith, Massey, James Jackson, Chapman, Beck, and a score or more of others. He then alluded by name to the various medical authors of the country, and to the value of their literary services. Sixty-five thousand physicians died during the century. The States were then taken up individually, beginning with California, and the names and services of the prominent medical men briefly referred to. No mere abstract can give an idea of the voluminous facts embraced in this valuable statistical paper.

THE ADDRESS ON THE ARMY MEDICAL WORK.

In the evening, in the hall of the Jefferson Medical College, Dr. J. J. Woodward, U. S. Army, gave a very interesting lecture, prepared at the request of the Centennial Medical Commission, on "The Medical Staff of the United States Army, and its Scientific Work." He alluded to the numerical strength of the army, the number of permanent detached posts, exposed as some of them are to malarious influences and Indian conflicts, the duties of medical officers, their supervision of all sanitary matters connected with them, of wounds, etc.

He sketched the nature of all the papers and reports connected with the medical service. 200,000 had died of sickness during the war; 100,000 of wounds. 16,000 volumes of manuscript record books, and many tons of papers of all kinds, came back to the Surgeon-General when the hospitals were closed after the war, all of which had to be examined and analyzed. It would

have been a great national crime not to have done so, and not to have extracted from them the immense amount of material they contained for scientific and useful purposes. No great national medical library existed at the beginning of the war; nor was there any great pathological museum. Valid reasons for the establishment of each at Washington, under national auspices, were given by the speaker. The whole medical staff of the army had contributed to both, but the heavy labor had been performed by three Assistant Surgeons, Drs. Billings, Otis, and Woodward, without extra compensation, in addition to their other administrative work.

Since 1865, the history of 300,000 cases had been traced through the records of the Surgeon-General's office, but, from want of proper clerical force, 12,000 to 13,000 applications were now lying unanswered, the number of clerks being reduced from 100 to less than half that number. Over 6,000 quarto pages of publications have thus far been issued from this office. The reports on meteorology, formerly published, are now discontinued, the Signal Office having taken charge of this branch of inquiry. Other reports emanating from the Surgeon-General's office were referred to, as that of Dr. Billings on posts and hospitals, the records of physical examination of recruits, the report of Dr. Ely McClellan on Cholera, etc. The importance of the chemical laboratory connected with this office was dwelt upon.

The volumes of the "Medical and Surgical History of the War" were the records of 270,000 cases. Cheney, in his medical statistics of the war of the Crimea, had 40,000 cases to describe, and 17,000 in the Italian war; but they were not subsequently followed up, as they have been with us. The National Medical Library at Washington now contains 40,500 bound volumes and 41,000 pamphlets. 275,000 cards of all the subjects in the books and journals of this library await the hands of the printer. The catalogue *raisonné*, when published, will make five volumes of 1,000 pages each. The Army Medical Museum contains 19,000 specimens, illustrating military surgery and camp diseases during the war. The hope is, to make this also a general pathological museum. It contains 1,500 skeletons and crania; 1,600 crania alone from all countries, with complete measurements by Dr. Otis. This museum, if added to from private sources, would be especially valuable, particularly if they were specimens which have formed the basis of original researches.

Dr. Woodward then gave an exhibition with the magic lantern, of pathological specimens, microphotographic sections, etc. The thanks of the Congress ere tendered him for his very interesting address.

The Congress met again on Thursday morning, the President in the chair. Drs. Bowditch, Woodward, and Seguin were announced as the delegates to the International Congress at Geneva, to confer on the arrangement of a plan for an international system of medicine and medical observation, in accordance with the action taken on Wednesday.

422 names on the Register were reported by the Secretary-General.

AN APPEAL TO CONGRESS TO SUSTAIN THE SURGEON-GENERAL.

On motion of Dr. Bowditch, the following resolutions were adopted:

Whereas, The work already accomplished by the officers connected with the Bureau of the Surgeon-General of the United States, in the establishment of a medical library, in the preparation of its ample and unique catalogue, and in the formation of an anatomical museum, from which important scientific results have already been obtained, and which have been not only a source of honor to these United States, but of value to foreign lands, and wherever science is cultivated; and

Whereas, This Congress learns with regret that, owing to a lack of a sufficient clerical force and of pecuniary means, not only some of the work already in progress has been suspended, but that other work of equal value cannot be undertaken, although ample materials for the same are now lying unused in the Surgeon-General's office; therefore,

Resolved, That a committee of three be appointed to prepare a memorial to the Congress of the United States, at the earliest day possible, at its next session, urging efficient support to these most important matters.

Resolved, That it is desirable that said memorial should be signed by the president, vice-presidents, and permanent secretary of this body.

SANITARY WORK.

On motion of Dr. J. P. White, of Buffalo, it was ordered that Dr. Bowditch's address on Sanitary Science be transmitted, when printed, to the Presidents of State and Territorial Medical Societies, and Sanitary Boards of the United States and Canada.

Reports from the various sections were then read, accepted, and referred.

On motion of Dr. Richardson, of New Orleans, Dr. Woodward was requested to repeat his lecture of last evening.

THE ADDRESS ON OBSTETRICS.

Prof. Theophilus Parvin, of Indiana, then read the address on Obstetrics. Many improvements in the art may be mentioned, and many advances in the science, notwithstanding Prof. Ramsay, of South Carolina, in the latter part of the last century, declared that obstetrics was so perfect that no improvement was possible. The speaker referred to those prominent at the end of the century—Baudelocque, with his twenty-three presentations and ninety-four positions; Smellie, William Hunter, opposites in views of obstetrics, mechanism, and physiology; Levret, and others. Lloyd in Boston and Shippen in Philadelphia were the earliest American practitioners of distinction. He then referred to Drs. James and Dewees, and their connection with obstetrics in America, the latter giving the first full course of obstetrics in this country. Seventy or eighty years ago the practice of obstetrics was chiefly in the hands of women, and was not lucrative, the compensation being only a dollar—in cities, three dollars—and the accoucheur, or rather accoucheuse, was nurse until the ninth day, and no posthumous honors attended their laborious work.

Bard's compendium was the first work on obstetrics in America. The speaker then alluded to other successful and useful American works, giving sketches of Dewees, and his successors and contemporaries—with criticisms, favorable and unfavorable, of their writings and teachings—as Meigs, Miller, Bedford, Hodge, Tucker, Warrington, Byford, and others. He gave an insight into the numerous treatises and papers on obstetric anatomy, and contended that the improvements in obstetric surgery saved more lives and was the means of relieving or diminishing suffering more than the changes in medicine or surgery proper. The history of the discovery of the anæsthetic effects of

ether and its application to obstetrics was sketched, and the names of numerous authorities who early employed it or wrote papers about it were mentioned.

The use of chloroform and of opium in obstetric practice; the practice of feeding women in labor; the induction of labor in placenta prævia, and in other conditions; the employment of ergot in labor for two most important purposes, etc., etc., were alluded to, with the names especially of Americans who had either first suggested them or improved on the methods of others. He also referred to bimanual turning, cephalic by Wright, or podalic version by Hicks; the treatment of prolapsed cord by Thomas, and others; postural treatment in complicated labor cases; head-last labors, described by Goodell, Parry's correction of faulty positions, Gibson's Cæsarian operations, operations of gastro-elytrotomy, etc., and stated that a full bibliographical appendix would accompany the paper.

The various American works on Diseases of Women were briefly enumerated, criticised, and discussed, such as those of Dewees, Meigs, Bedford, Thomas, and others. In uterine surgery much has been done; a tribute was paid to Sims and Emmet for their treatment of fistula, and to Atlee and Peaslee for their contributions to ovarian surgery. The positional disorders of the uterus were referred to, with an account of the various modifications of the pessary, the use of pneumatic pressure by Campbell, of Georgia, the different modes of treatment for inversion, by J. P. White, Emmet, and others; he discountenanced, as the profession does, resort to abdominal section in such cases. The use of glycerine and hot water was spoken of; the latter was claimed by Emmet to have been originated entirely by himself, to insure permanent contraction of the vessels. American suggestions had also been made in the division of stricture of the uterus in dysmenorrhœa, amputation of the cervix uteri, the application of fluids to the lining membrane of the uterus, the treatment of uterine fibroids, electrolysis and ergot, and their complete ablation being also referred to in this connection, the removal of the uterus itself by Prioleau, of South Carolina, in 1819, etc.

Operations for genito-urinary fistula and for removal of various tumors are two of the greatest triumphs of American obstetric surgery. The names of various Americans were mentioned by the speaker as foremost in these fields. For ovariotomy, McDowell operated thirteen times, with eight recoveries. Spencer Wells lost four of his first thirteen; Baker Brown eight. The English claims to priority were examined and set aside. More than 2,000 women's lives have been saved by this operation. Allusion was made to the early American ovariotomists, to Dr. Drysdale's discovery of the ovarian cell, to the various operations, as enucleation of cysts, obliteration of the vagina, vesico-vaginal operations, as vesico-vaginal lithotomy, etc., of American surgeons.

American works on diseases of children by Dewees, Eberle, Stewart, Condie, Meigs and Pepper, and others, were mentioned, as well as works on special infantile diseases. The formation of obstetrical and gynæcological societies, hospitals, and journals, was rapidly sketched. The speaker alluded also to the presence of two distinguished obstetricians of Great Britain—Barnes and Simpson, and concluded his excellent address with a beautiful peroration.

THE ADDRESS ON MEDICAL JURISPRUDENCE.

Prof. Stanford C. Chaillé, of Louisiana, then read the address on this subject, giving a sketch of the general progress of Medical Jurisprudence for two centuries, alluding particularly to the barbarous views and absurd and superstitious practices of even the last century, such as those associated with the bleeding of wounds, legal decisions affirming paternity from a dream when a husband had been absent four years, the burning alive of those suspected of crime as late as 1780, etc., etc. In 1774 the first law was passed in England to improve the condition of the insane; Pinel first suggested their humane treatment as victims of disease.

The speaker then inquired, with painfully negative replies, what our laws have done to apply medical knowledge to the administration of justice; what efforts to secure the best medical talent in criminal cases; what experience the medical witnesses have had—what information or experience the judges. There are several thousand cases in the United States annually requiring medico-legal inquiry; the coroners, unless by accident, have no experience or information to guide them; any practitioner who calls himself so can be a medico-legal witness.

The first Chair of Medical Jurisprudence in the United States was created in 1813, in the New York College of Physicians and Surgeons. There are now sixty regular colleges in existence. Of forty-six of these, twenty-one do not profess to teach this branch, fourteen have separate chairs—some of them taught by lawyers, and in eleven it is a caudal appendage to other branches.

Allusion was made to a few American contributions to medical jurisprudence, as the corpus luteum of Dalton, and Richardson's employment of high powers in blood-stains. The bibliography of the subject is very full, and will make a valuable addition to Prof. Chaillé's paper. The contributions of Americans to its literature have been but trifling, but they were briefly enumerated by the speaker, as were also the various works and papers on the medical jurisprudence of insanity. In examining the subject of medico-legal progress in institutions, laws, and judicial decisions, he alluded to the fact that in 1874 there were in the United States seventy-seven life insurance companies, insuring $2,220,000,000 on 910,000 policies. The deaf and dumb were formerly considered legal idiots; medico-legal inquiry has now nothing to do with them.

He next spoke of the legislation for habitual drunkards in some of the States, and of the enactments in Maine and New York for the examination of criminals in cases when a plea of insanity was offered, and of the various steps of progress in judicial decisions since the days when protection to the insane was restricted to such as had no more knowledge or control over themselves than mere brutes, and when the Lord Chancellor of England urged the absurdity of calling insanity a disease. He praised the labors of the Medico-legal Society of New York, and its objects, and the good work it was likely to accomplish; and concluded his valuable paper with an exposition of the necessity of competently instructed State experts, reformation in the coronerships, competency of witnesses and judges, and proposed various methods to secure all these good results.

On Friday, President Gross in the chair, the General Secretary reported the number registered as four hundred and thirty.

AN UNNECESSARY AND STUPID RESOLUTION.

Prof. Eve then offered the following resolution at the request of Dr. William B. Atkinson, of Philadelphia:

Resolved, That no papers or addresses read before

this body, and ordered to be published, shall be furnished, either in abstract or otherwise, for publication in any journal prior to the publication of the volume of Transactions.

The reports of Sections were accepted and referred; that on surgery being referred back to that section for an expression of views on Dr. Sayre's treatment of coxalgia.

THE PUBLICATION OF THE TRANSACTIONS.

On motion of Dr. Davis, the following preamble and resolutions were adopted :

WHEREAS, This Congress marks an era in the history of medicine in the United States of America, the addresses delivered presenting a summary of progress in the various departments, which will be of great historical value in all coming time; and

WHEREAS, It is highly probable that these addresses, in connection with the many very valuable papers read and discussed in the Sections, will require for their early and proper publication more money than will be in the hands of the Treasurer for that purpose; therefore,

Resolved, That the Committee of Publication be authorized and instructed, as soon as practicable after the final adjournment of the Congress, to ascertain the probable cost of publishing the full Transactions in a style appropriate for the work, and if the money on hand is found deficient, they shall address a circular letter to each American member of the Congress, asking for such additional sum, not exceeding ten dollars, for each of such members as will supply the deficiency; and that said Committee be authorized to withhold the volume or volumes, when published, from any member who may neglect or refuse to pay the additional sum required.

Resolved, That the Committee on Publication be authorized and requested to exercise a careful and liberal discretion in preparing and revising the proceedings and reported discussions, in the several Sections, for publication in the Transactions of this Congress.

THE TEMPERANCE QUESTION.

Resolutions were received from various temperance organizations, and these were referred, at Dr. Davis's suggestion, to the Section on Medicine.

THE ADDRESS ON MENTAL HYGIENE.

Dr. John P. Gray then read the address on mental hygiene, Vice-President McGuire, of Virginia, in the chair. Beginning with some introductory remarks on mental capacity, he divided his address into the individual, social, and national relations of this form of hygiene. He referred to the bearing of intellectual and physical labor on longevity, the effect of training on manners and habits as exemplified in soldiers, schools, etc.; and to the various social restrictions and regulations as connected with mental hygiene; and to the apparent conflicts between science and religion. Only lately has mental hygiene been particularly demanded in the progress of science as a separate study. The "Rules of Health" of the School of Salernum were quoted, and reference made to the lessons taught by the Exposition, showing that in some countries—as Egypt—the characteristics of many centuries since still pervaded it.

He concluded by reciting the various lessons that could be deduced from the study of mental hygiene.

The address, which was well written and well delivered, was of so general a nature as not to admit of a satisfactory abstract. It differed from all the others in being almost entirely devoid of purely American applications.

THE ADDRESS ON MEDICAL LITERATURE.

Prof. Lunsford P. Yandell, of Kentucky, then read the address on this subject, Vice-President Richardson, of New Orleans, in the chair. His researches had gone back even prior to the last century. He gave a glance at the names of authors, with the titles of books, but did not attempt to catalogue them in the address as delivered. (This paper, when printed, will contain a complete list of American medical works in the order in which they have appeared). He referred to the earlier works that had been published in this country; to Thatcher's various contributions, to the papers and works of writers on yellow fever, small-pox, etc., in the last century, almost all of which were brief, of transient interest, and hardly more extensive than articles in the medical journals of the present day. He alluded to the establishment of medical schools in this country; to Rush and his literary labors, to Currie, Bailey, Mitchell, Miller, Smith, and others of that day; to Caldwell, and his abilities and peculiarities.

The general character of our American medical literature was referred to, and the fact stated that while a text-book in the Italian schools has continued to be such for two hundred years, the most successful of our own scarcely ever reach beyond forty years. The appearance of the first American medical journal in 1797, was alluded to, and the number of those projected since, fixed at about one hundred, of which over fifty have been withdrawn.

The address was cut short by the expiration of the time allotted to it.

PUBLIC DINNER OF THE CONGRESS.

In the evening the public subscription dinner of the Congress was given at St. George's Hall. Nearly two hundred members and guests participated, including the Governor of the State, and all the distinguished foreign and American representatives of the profession attendant on the Congress. Replies to toasts were made by Prof. Joseph Lister, Governor Hartranft, Dr. Woodward, U. S. Army, Gen. Hawley, President U. S. Centennial Commission, Prof. Hjort, of Norway, Profs. J. C. Dalton and Stillé, Mr. William Adams, of London, Dr. Hingston, of Montreal, Profs. Davis, of Chicago, and Chaillé of New Orleans, and Prof. Gross.

On Saturday, President Gross in the chair, those whose names had been reported as on the Register, four hundred and forty-three in all, were confirmed as members of the Congress.

The Secretary-General was extended the privilege of giving Prof. Rudnew, of Russia, facilities of access to the minutes and papers of the Congress, for transmission of an abstract to Russia.

THE CONGRESS NOT PERPETUAL.

Reports were received from the various Sections, but some little discussion took place on that of the Dermatological and Syphilological Section, which was anxious to have a committee appointed in the name of the Congress, to collect data and statistics in regard to syphilis, and report them to the public press; but it was held that no such irresponsible work could be done, when the Congress itself would this day expire.

THE TEMPERANCE QUESTION AGAIN.

In reply to the temperance communications received yesterday, the conclusions adopted on the paper of Dr. E. M. Hunt, of New Jersey, on alcohol, were ordered to be transmitted to these organizations:

1. Alcohol is not shown to be a definite food by any of the usual methods of chemical analysis or physiological investigation.

2. Its use as a medicine is chiefly that of a cardiac stimulant, and often admits of substitution.

3. As a medicine it is not well fitted for self-prescription by the laity, and the medical profession is not accountable for such administration or for the enormous evils arising therefrom.

4. The purity of alcoholic liquors is in general not as well assured as that of articles used for medicine should be. The various mixtures when used as medicine should have definite and known composition, and should not be interchanged promiscuously.

CONGRATULATIONS ON THE SUCCESS OF THE CONGRESS.

Then followed a scene that will long be remembered by those who participated in it, the interchange of personal, national, and international greetings on the remarkable success of the Congress. This was opened by the following resolutions, offered after a speech abounding with complimentary allusion, by Prof. J. P. White, of Buffalo:

Resolved, That the officers and trustees of the University of Pennsylvania are hereby tendered our cordial thanks for the very liberal use of their excellent buildings for the meetings of this International Medical Congress.

Resolved, That the officers and trustees of the Jefferson Medical College are hereby tendered the cordial thanks of this Congress for the use of their lecture-room for the most interesting lecture of Dr. J. J. Woodward, U.S.A.

Resolved, That the Centennial Medical Commission of Philadelphia are hereby tendered the cordial thanks of this Congress for the most excellent manner in which its members have discharged the arduous duties devolved upon them, and by which our pleasure and profit have been so much enhanced.

Resolved, That the president and other officers of the International Medical Congress of 1876 are hereby tendered the cordial thanks of the Congress for the excellent manner in which they have discharged the arduous duties devolved upon them, and by which our pleasure and profit have been so much enhanced.

Resolved, That the cordial thanks of the International Medical Congress are especially due to Drs. Thomson, Wilson, and Strawbridge, and to Messrs. H. C. Lea and J. B. Lippincott, for their generous hospitality.

These were adopted amidst great applause.

A TRIBUTE FROM CANADA.

Dr. Grant, of Ottawa, eloquently addressed the Congress in a very fraternal vein, and reported the following resolutions, adopted yesterday at a meeting of the Canadian delegates to the Congress:

Resolved, That the Canadian members of the International Medical Congress desire to express their sense of the great consideration and urbanity with which they have been treated by the officers and members of the Centennial Medical Commission, and beg by this resolution to tender their warm thanks for the same.

Resolved, That the Canadian members of the International Medical Congress most cordially join with the other members of the Congress, in thanking the members and citizens of Philadelphia for the generous hospitality extended to its members throughout the present session.

THE DELEGATES FROM GREAT BRITAIN.

Prof. Charles J. Hare, of London, then read the following expression of congratulation on the part of these gentlemen:

"The delegates from Great Britain to the International Medical Congress at Philadelphia beg to congratulate the President and the several committees on the complete success of the Congress, on the high value of the various addresses presented to it, and on the forward impulse which it has given to the progress of medicine in the widest sense of that word. They desire at the same time to express in the strongest and warmest terms their sense of and their thanks for the unmeasured kindness and courtesy, and the unbounded hospitality with which they have been received on this Centennial occasion, and to add that they will carry back with them a most grateful recollection of that warm right hand of fellowship which has been so warmly extended to them by their brethren of the United States."

The paper was signed on behalf of the delegates by Dr. Hare, late Professor of Clinical Medicine in University College, London; Mr. R. Brudenell Carter, Hunterian Professor of Surgery in the Royal College of Surgeons of England; and Mr. William Adams, President of the Medical Society of London.

THE COMPLIMENT RETURNED.

On motion of Dr. Bowditch, it was

Resolved, That we, a brotherhood of physicians from the North, South, East, and West of this country, hereby tender to our associates from other lands our most earnest wishes that they may have safe and happy returns to their homes, and we would suggest the hope that they will carry back many pleasant memories of this fraternal meeting now closing, and which has been most appropriately held in this generous and noble city of Philadelphia.

A PORTRAIT OF PROF. GROSS.

Prof. Sayre, of New York, offered the following resolution, which was seconded in a beautiful little speech by Mr. Carter, of London, and cordially adopted by the Congress:

Resolved, That this International Congress request our President, Prof. Gross, to sit for his portrait, and that the Committee of Publication be instructed to have the same engraved and printed in the frontispiece to the volume of our Transactions.

(It is understood that, for sake of correctness, this shall be a photographic likeness, unless otherwise ordered by the Committee.)

The General Secretary presented the preliminary circular of the International Congress of 1877, at Geneva.

THE ADDRESS ON MEDICAL EDUCATION AND MEDICAL INSTITUTIONS.

Prof. Davis, of Chicago, then read the Address on these subjects. He alluded to the early colleges, to the organization of a very few societies during our colonial history, to the qualifications necessary at that time for the physician and surgeon, to the early laws in force affecting them, the modes of examination, etc. In 1752 was founded in Philadelphia the only

general hospital in the country. There were soon after 3.000 practitioners in thirteen States, only two medical colleges, and two organized medical societies. He referred to the early establishment of schools in Philadelphia, the degrees then conferred, with sketches of the relations existing between the schools of that city in the latter part of the century, with the regulations of each for study and graduation. Succeeding schools were also mentioned.

Columbia College, New York, was the first to confer degrees of Doctor of Medicine. The "Doctor's Mob" in New York was referred to; also the interruption by the war of the courses of lectures, the various changes in the faculties, the establishment of the College of Physicians and Surgeons of New York, the organization of schools elsewhere, the apprenticeship system and its effects upon the student, the abolition of the degree of Bachelor of Medicine, etc. The speaker next alluded to the kind of medical works in use at the beginning of the century, and to the limited field of medical science at this time. A detailed account accompanied the report, enumerating all the medical colleges founded since the beginning of the century, with their dates of institution. From the close of the war to the present time, 77 colleges have been founded, not counting a few very transient and ephemeral ones. Sixty-one are now in active operation. In 1875-6, there were in all the States 6,650 students, of whom more than 2,200 received the degree that session, not including those in pharmacy or dentistry, or those conferring degrees founded on exclusive dogmas. Generally medical education is not dependent on legislative aid.

The adaptation of medical schools to the wants of the people and the profession was then discussed, and among other things the conferring of degrees by colleges. No matter how incomplete the course or how defective, the amount of chemical teaching was criticised, as well as the crowding of a whole course into a period of sixteen to eighteen weeks. The faults and shortcomings of the office-student system were considered; the propriety of restricting medical colleges to teaching merely, without making them at the same time licensing boards for examination; the efforts of State medical societies to this end; the conventions of schools for improvement in education; the reform instituted by Harvard and others; and the influence of medical societies, socially and in the character of the papers presented, etc.

THE LAST MINUTES OF THE CONGRESS.

After a few well-expressed remarks as to the inestimable value of the Congress, and of good wishes for all the members now about to separate, the President announced the labors of the Congress completed, and that body then adjourned *sine die*.

Its proceedings will long be memorable, for the Congress was confessedly the most successful medical gathering ever held in this country.

New Method of Removing a Foreign Body from the Ear.—Take a horse's hair about six inches long, and double it so as to make a loop at one end. Introduce this loop as deeply as possible into the auditory canal and twist it gently around. After one or two turns, according to the originator of the plan, the foreign body is drawn out with the loop. The method is ingenious, and at all events causes little pain, and can do no harm.

NEW YORK PATHOLOGICAL SOCIETY.

Stated Meeting, June 26, 1876.

Dr. C. K. Briddon, President, in the Chair.

MULTILOCULAR OVARIAN CYST.

Dr. A. Clark presented the contents of an ovarian cyst, removed post-mortem from a maiden lady, aged 64 years, who had died of cancerous disease of the pylorus. The specimen was sent to him by Dr. W. M. Trow, of Haydenville, Mass., the attending physician. There was nothing special in the history of the case. She was never inconvenienced by the pelvic trouble, her symptoms being those of scirrhus of the pylorus, unless it was that she did not suffer the slightest pain during the progress of the disease. The ovarian tumor contained a purulent fluid and a mass of substance composed for the most part of oily matter and an abundance of epithelial scales and flat, rounded cells. In the midst of this fatty mass there was a bundle of hair, measuring two and a half inches in one direction and two inches in another.

Although the tumor had been mislaid for three months, wrapped in a newspaper, it had shown no signs of putrefaction.

Dr. Heitzmann reported that the tumor of the skin removed by Dr. Briddon, and presented at the previous meeting, was of an acute and malignant nature, and was of the variety designated as papillary epithelioma. So far as the microscopical examination showed, the extirpation was complete.

He also reported the tumor of intestine and omentum, presented by Dr. Hinton, to belong to the variety of myxomatous cancer.

MORBUS COXARIUS, AND EARLY OPERATION.

Dr. Sayre presented the hip-joint removed from a child who had been the subject of operation for exsection, and who died of meningitis. Although operated upon when almost in articulo mortis, and with the worst possible hygienic surroundings subsequently, nature made a very successful attempt to enclose the severed end of the bone in a new capsule, and form a new joint cavity.

Dr. Sayre exhibited a second specimen of morbus coxarius, being that portion removed by operation from a child three and a half years old. This was the only one in which, in his experience, the operation had been performed without suppuration being present. With this exception, all the other signs of the third stage were well pronounced. On cutting down upon the joint, the synovial membrane was found to be degenerated, and the ligamentum teres destroyed. The operation had been performed seven weeks, but there had been no signs of suppuration, and the patient was doing well.

Dr. Sayre lastly exhibited an encysted tumor of the outer side of the leg, which had been the occasion of a rupture of a vein and extensive ecchymosis.

SARCOMA OF THE SKIN IN SOME RESPECTS RESEMBLING KELOID.

Dr. Satterthwaite presented the notes of the following case:

Louis Prewitz, 43, Germany, was admitted into the Presbyterian Hospital, May, 17, 1876, for a growth upon the left side of his neck and shoulder, and he gave in substance the following history. Fifteen years previously, a wart appeared upon the neck, and

as it gave him some annoyance from bleeding freely when his clothes pressed upon it, he had it tied off. This was done in 1861. The tumor, however, grew again, but was finally rubbed off by his clothes; again, a third time, it grew, and got to be as large as a small nut; it was again tied off, and again, the fourth time, grew, when it was cut off by a surgeon. The wound healed entirely, but soon there appeared under the scar a "bluish boil," as the patient expressed it. At this point the tumor appeared again for the fifth time. A surgeon at the German Dispensary removed it, in 1875. Since that time several growths sprang up, and the skin became affected, which was not the case before, as the disease was confined to a single pendulous nodule. The patient said that his general health had not been affected by the growths, except from the loss of blood, which had been considerable at times when the clothes irritated them.

When admitted into the hospital, the following notes were recorded in the case-book: "The tumor is a fungous-looking mass about the size of a man's fist, somewhat lobular and pedunculated. . . . It is situated over the upper portion of the left scapula. The tumor is not adherent to the muscular layer. Running out from the tumor in three directions are elevated ridges about the size of a man's finger, resembling cicatrices. The longest, four inches in length, runs across the neck to the right. On May 25th, a very large portion of the tumor was removed, including all the pedunculated growths. The patient has done remarkably well since the operation, and the wound is in a great measure closed.

Microscopical examinations, May 24, 1876.—The portion examined was one of the pedunculated nodules; it was soft, and of a pale pinkish consistence. Externally it exhibited the normal constituents of the skin, but in a hypertrophied condition.

"The horny layer was intact, and measured from $\frac{1}{600}$ to $\frac{1}{300}$ of an inch in thickness. The rete Malpighii, from the bottom of the horny layer to the summit of the papillæ, measured from $\frac{1}{100}$ to $\frac{1}{60}$ of an inch.

"The length of the papillæ varied between $\frac{1}{50}$ and $\frac{1}{10}$ of an inch. The surface of the skin was nowhere broken. The tissue occupying the position of the corium was that mainly of which the tumor was composed. It consisted chiefly of fusiform elements, closely packed together, and formed into bundles in many places; these elements were large, flattened, and fusiform, containing a flattened rounded corpuscle. These elements extended upwards into the papillæ; many of them could be isolated, and then they were seen to have a length of from $\frac{1}{500}$ to $\frac{1}{1000}$ of an inch. The central body had a length of between $\frac{1}{300}$ and $\frac{1}{250}$ inch. Vessels were numerous, their walls being composed of the same tissue. From the histological character of the growth, it was said to be a fibro-plastic tumor, or spindle-celled sarcoma of the skin. The special interest which attached to the specimen was, that by some it had been regarded as a keloid undergoing degeneration. The hard ridges had the appearance of keloid to the eye, but the microscope showed that the tissue composing them was made up entirely of the fusiform elements, and not the wavy bundles of fibrillated connective that belong to either class of keloid, the true or false."

INFANTILE DIARRHŒA is the subject of discussion in the English journals. We are pleased to notice the respectful consideration with which the views of our fellow-townsman, Dr. J. Lewis Smith, are received regarding the pathology of the affection.

Reviews and Notices of Books.

REPORTS AND PAPERS RELATING TO THE CONSTRUCTION AND ORGANIZATION OF JOHNS HOPKINS HOSPITAL. No. I.

THIS brief report of Dr. J. S. Billings, U.S.A., is called forth by the request made to him by the Trustees to present his views on the various plans and drawings of the architect and building committee for the Johns Hopkins Hospital. It is marked by the sanitary skill and prevailing good sense of the author. Although brief, it succinctly presents the points at issue in the erection and general administration of the institution.

The ideas of charity education and science are clearly brought out as dwelling in the mind of the donor. It is shown how these can be constantly exercised and combined. The clinical education of the student does not involve the necessity of bringing a delicate patient "before unsympathetic, noisy students, to be lectured over as if he were a curious sort of beetle." The charity itself conveys the idea that it is to benefit not only those treated within its walls, "but the sick and afflicted of all countries and of all future time." He rightly insists that in a higher method, such as may be adopted here, it is quite possible to educate the student clinically, and yet not annoy the patient.

It is claimed that much of the value to students is to be in rooms for apparatus, observation and experiment, and so in opportunities for scientific investigation in the line of physics. It is an important problem how to harmonize the greatest good to the patient, the physician, and the public; but it can and will be done.

Nothing can be plainer than the design of the founder to have the Hospital "form a part" of the medical school of the University.

The training of men as special investigators, as sanitarians in relation to State and municipal interests, as alienists, and as to child diseases, are particularly referred to. Thorough courses are insisted upon not only for the future, but as preliminary, so that the very men chosen for special departments shall beforehand prove their ability. He purposes that there shall be as much difference between these and the average medical student as between an architect and a bricklayer. It is true that the real hospital "consists of the brains to be put into it." It is plain that the relations of the hospital, its structure and its administration, have intelligent and well-drawn outlines in the mind of the author.

PREVENTION OF YELLOW FEVER BY WHISKEY.—Dr. A. N. Bell, of Brooklyn, writes: "In the RECORD of 19th inst., the report of my remarks at the recent meeting of the American Medical Association on the 'Prevention of Malarial Fevers,' is erroneous. I never said that at Vera Cruz, or anywhere else, I advised the use of whiskey as a prophylactic of yellow fever, or of any other disease. On the contrary, I probably stated that a popular error prevailed at Vera Cruz at the time referred to, 1847–'8, that whiskey was a prophylactic of yellow fever, and that its use was encouraged by those who were fond of it, with fatal effect."

Correspondence.

THE CAUSE OF CHOREA.

To the Editor of The Medical Record.

There is an old and familiar story of an individual who covered the eyes of his horse with green glasses, and placed before him a basket of shavings, with the idea that the unsuspecting animal would believe them to be grass. I think at some time or other we are all apt to look through glass of one color, when the object is likely to appear more attractive. As a case in point, I would refer to a paper which recently appeared in the Medical Record, and in which the author considers a well-known form of nervous disease to be due to certain errors of refraction. The same gentleman made the unqualified statement, at a meeting of the Academy of Medicine, on the fifteenth of June last, that chorea, as well as all functional nervous diseases, were in his opinion due to this cause in the great majority of cases. If this is the fact, it is about time for neurologists to buy green spectacles, or else renounce their specialty. But before doing so, it might be well to test the truth of the theory Dr. Stevens announces so confidently. Surely, the etiology of chorea is well understood, although its pathology is not so clearly settled. If we exclude bad habits, bad air, bad food, fright, improper mental hygiene and example, and consider the eyes at fault in every choreic patient—we at the same time must forget that proper diet, sufficient pure air, mental rest—medicines (which are almost specifics) and other management will cure our patients without the use of glasses. That these cases very often recover spontaneously—that persons who are even *blind* may suffer from chorea, as well as other functional neuroses—should also be taken into consideration.

To test the question, I have examined a number of individuals, half of whom are perfectly healthy, and the other half are patients under my care—some of them have chorea. I have been unable to find any preponderance of astigmatism, myopia, or hypermetropia in either class. That the muscles of accommodation as well as others of the body may become the seat of spasm *after the disease is established*, I have no doubt; but as a cause, I do not agree with Dr. Stevens. All of the author's cases were examined after the appearance of the chorea. If he could have examined them before, no one would have been more ready to be convinced than myself.

Allan McL. Hamilton.

123 East 30th St., Sept. 5th.

ARMY NEWS.

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from Sept. 3d to Sept. 9th, 1876.

Alden, C. H., Surgeon. Assigned to duty as Post Surgeon, at Fort Townsend, W. T. S, O. 112, Dept. of the Columbia, August 25, 1876.

Byrne, C. C., Surgeon. Assigned to temporary duty with troops encamped on site of new post on Yellowstone River, M. T. S. O. 106, Dept. of Dakota, August 30, 1876.

Sternberg, G, M., Surgeon. Assigned to duty as Post Surgeon at Fort Walla Walla, W. T. S. O. 112, C. S., Dept. of the Columbia.

Billings, J. S., Asst. Surgeon. Granted leave of absence for three months, with permission to go beyond sea. S. O. 182, A. G. O., Sept. 2, 1876.

Buchanan, W. F., Asst. Surgeon. Assigned to temporary duty at these Headquarters pending his summons as a witness before a General Court Martial. S. O. 161, Dept. of Texas, August 29, 1876.

Wolverton, W, D., Asst. Surgeon. Assigned to duty as Post Surgeon at Standing Rock Agency, D. T. S. O. 106, Dept. of Dakota, August 31, 1876.

Carvallo, C., Asst. Surgeon. Assigned to duty at Fort Union. N. M. S. O. 184, Dept. of the Missouri, September 4, 1876.

Maus, L. M., Asst. Surgeon. Granted leave of absence for one month with permission to apply for an extension of one month. S. O. 132, Dept. of the South, September 2, 1876.

Corbusier, W. H., Asst. Surgeon. Assigned to duty at Fort Macon, N. C. S. O. 133, Dept. of the South, September 5, 1876.

Ainsworth, F. C., Asst. Surgeon. His resignation accepted by the President to take effect November 10, 1876. S. O. 182, A. G. O., September 2, 1876.

Medical Items and News.

Contagious Diseases.—Comparative statement of cases of Contagious Disease reported to the Sanitary Bureau, Health Department, for the two weeks ending September 9, 1876.

Week Ending	Typhus Fever.	Typhoid Fever.	Scarlet Fever.	Cerebro-Spinal Meningitis.	Measles.	Diphtheria.	Small-pox.
Sept. 2.....	0	18	12	0	1	21	0
Sept. 9.....	2	19	8	3	2	22	1

Japan and the Medical Congress.—The Japanese government appointed three physicians as delegates to the congress. Nagayo Sensai and Miyaki-Kūdzu were sent by the Minister of the Interior, and Ishiguro Tadanori is a member of the medical staff of the Minister of War.

The Wiener Medicin Doctoren Collegium appointed Dr. Charles Heitzmann, of New York (Vienna, 1859). Dr. Lander Brunton was a delegate from the Medical Society of London, and Dr. Charles John Hare, Dr. Robert Barnes, and Mr. R. Brudenell Carter, from the Royal Medical and Chirurgical Society of London, Dr. Hare representing also the Pathological Society.

The Preservation of Ice at the Bedside.—Mr. Samson Gamgee employs the following simple plan for the preservation of ice in the sick-room. A piece of flannel about nine inches square is secured by a cord about the mouth of an ordinary tumbler, so as to leave a cup-shaped depression of flannel within the tumbler to about half its depth. Small pieces of ice placed in this flannel cup, and loosely covered with another piece of flannel, may be preserved for hours.

Cheap flannel with comparatively open meshes is preferable, as it allows the water to drain through, and the ice is thus kept quite dry. If good flannel with close texture be employed, a small hole should be made in it to allow of drainage. Mr. Gamgee found by experiment that in a room of 60 F., two ounces of ice broken in pieces suitable for sucking and placed loosely in a tumbler, were entirely melted in two hours and fifty-five minutes. The same quantity of ice in a cup, made as above described of good Welsh flannel, took six hours and a half to melt, while the same quantity placed in a cup, made of cheap open flannel, lasted ten hours and ten minutes.—*The Lancet*, June 10th.

The Medical Profession at Saratoga.—We have received a letter denying in toto the charges made by a resident physician of Saratoga against the metropolitan practitioners who visit that city during the fashionable season. The letter in question answers the allegations quite satisfactorily, but is too lengthy for publication. From what we know of the gentlemen against whom these charges have been made, and from what we have since learned, we believe that the writer of the article in question has been misinformed respecting the facts involved. We shall refer to the matter editorially in a future number.

The Medical Associations in New York.—During the past week the profession of this city have been busy in entertaining the foreign guests who were in attendance upon the Ophthalmological and Otological Congresses, and the American Gynæcological Association. The meetings of these bodies were well attended, and many interesting subjects bearing upon the respective specialties were discussed. The Ophthalmological and Otological Congresses were of an international character, and were well represented by delegations from the European centres. The establishment of these associations is an evidence of the progress of specialism, and of ardor in the pursuit of these departments of science, which is in keeping with the spirit of the age. The Gynæcological Association, although a younger brother, has proved itself by no means a feeble one, and is destined to be a success from the start. The members of these associations who were in attendance were highly pleased, not only with the scientific but with the social part of the entertainment, heartily responding to the elegant and refined hospitality which was tendered them. The members of the Ophthalmological and Otological Congresses were handsomely entertained by the receptions of Dr. Agnew and Dr. Knapp, at the respective residences of these gentlemen; while the grand dinner fitly closed the festivities. The Gynæcological was not behindhand in enjoyment of the same kind of entertainments; besides the receptions, there having been an elegant dinner given by the New York and Brooklyn residents. The profession here know how to be hospitable, and their guests are always ready to appreciate the efforts made to entertain them. Of the strictly scientific character of the meetings we shall give an opportunity to our readers for judging when our reports are published.

Yellow Fever at Savannah.—Yellow fever is declared to be epidemic in Savannah, and is of an unusually malignant type, the death rate being thirty-one per cent.

Health of Watering-places.—The *Lancet* expresses considerable anxiety in regard to the present unsanitary condition of several of the leading health resorts of England.

Traumatic Tetanus in the Horse.—Mr. R. W. Finlay, V.S., of this city, sends us a report of two cases of traumatic tetanus in the horse cured by the following:

℞ Potass bromid..... ʒ iv.
Chloral hydrat..... ʒ ij.
Aqua..... ʒ viij.
M. Fiat sol.
S. To be taken in one dose and repeated three times daily.

The Medical Society of Yokohama, Japan, is the title of a new medical organization in Yokohama, Japan. The officers are: President, Dr. D. B. Simmons; Vice-President, Dr. Edwin Wheeler; Secretary, Dr. Stuart Eldridge.

The Croton Water.—The disagreeable taste and smell of the Croton water supplied to the city has now entirely disappeared.

How to Make Leeches Bite.—The *Le Progrès Médical* advises, in order to make a leech bite readily, to place it in a glass containing cold water, to wash the skin of the patient with warm water, and apply the glass at once.

A New University.—The Russian Government has issued a loan of $200,000, secured on the revenues of the State, for the creation of a University of Law and of Medicine at Tomsk, Siberia. Siberia has a population of six millions, and only one doctor for every 50,000 inhabitants. Russia has at present only seven universities, viz.: St. Petersburg, Moscow, Kiew, Kazan, Kharkow, Odessa, and Varsovia. That at Tomsk will be the eighth, and perhaps there will soon be another at Vlna.

Veterinary Supervision.—The Police Commissioner of Paris has appointed a staff of veterinary surgeons to watch over the sanitary state of horses used for trade purposes.

The British Army Medical Service.—The British Army surgeons in India are very much dissatisfied with the provision of the recent army warrant.

Suicides in the German Army are now on the decrease. The number of suicides is relatively highest in the Austrian Army.

Stevens' Triennial Prize—1879.—This prize, established by Alexander H. Stevens, M.D., amounts to two hundred dollars. The questions for 1879 are as follows:

I. "Bacteria and kindred organisms in their relation to disease."

II. "Human excreta as a cause of disease; the diseases produced therefrom and their prevention by hygienic means."

The competing essays on either of the above subjects are expected to give an account of our present knowledge, and also the results of personal investigation.

The essays must be sent in to the President of the College of Physicians and Surgeons, New York, on or before the first day of January, 1879. Each essay must be designated by a device or motto, and must be accompanied by a sealed envelope, bearing the same device or motto, and containing the name and address of the author. The envelope belonging to the successful essay will be opened, and the name of the author announced, at the Annual Commencement of the College, in March, 1879.

This prize is open for universal competition.

J. C. Dalton, M.D.,
Secretary of the Committee.

The Profession and the Newspapers.—The attention of the Council of the Medical Society of the County of Kings (N. Y.) has been called to the question of ethics involved in the publication by members of the Society of letters, etc., in the newspapers. The Council holds the opinion that the present sentiment of the profession does not favor medical communications of a personal character.

The accompanying notice was, in 1872, sent to all members, and it is again published in the Transactions as a reminder to delinquents:

"The Council desires to call the attention of members to the fact that the names of certain members of the Society have recently appeared in the public prints in connection with medical subjects. The Council having charge of the ethical relations of members hereby gives notice that such cases will be investigated."

The Council also calls to mind the fact that this Society has a standing Committee on Public Instruction, to which it would be fitting to refer all matters important to be made known to the public. If any member prefers not to act with that Committee, or if he thinks he has an especially urgent message to deliver to the laity, it would be in accordance with the spirit of our ethics to sink his personality for the time being. This may readily be done by the employment of an initial or *nom de plume*, instead of the full name, in or after articles intended for the medical edification of the secular press.

Death from Boxing the Ears.—Lancashire seems determined to obtain an unenviable notoriety in the peculiarity of the methods used for inflicting injuries. Some time since, the favorite weapon was the heavy boot shod with iron. The *Liverpool Post* now records an investigation made by the borough coroner as to the death of a scholar, aged 13, at Christ Church School, in Christian Street. The boy having been disobedient, and refusing to hold out his hand to be caned, was boxed on the ears by the schoolmaster. This occurred three or four months ago. A few weeks since, the lad, who had previously suffered from deafness, complained of a pain in his ears; and the medical evidence showed that death resulted from a long standing auricular disease. The doctor added that, whilst a blow might have irritated an already sensitive part, it would not have accelerated the boy's decease. The history is by no means clear, nor is the doctor's statement, as here recorded. The jury, in giving their verdict of "death from natural causes," added that, in their opinion, the punishment was administered injudiciously. With this opinion we quite agree. Injuries to the head are always alarming, but when the injury is localized so as to affect one of the special senses situated there, it is still more so. Injuries to the eye and ear are particularly to be avoided. These being organs of the utmost importance, consisting of the most fragile tissues, and partly exposed, we would impress upon all the danger of inflicting the slightest corporal chastisement in those regions. A comparatively slight blow on the auricular region, if it happens to compress the column of air in the meatus exactly, may cause a rupture of the membrana tympani. That this is not of unfrequent occurrence is well known to aurists. We are, however, of opinion, that, considering the pressure which the healthy tympanic membrane has been found to resist without rupturing, the membrane which gives way to such a blow has probably not been in a healthy condition at the time of the injury. The suddenness of the blow is also, we believe, an important element. The history given of most of the cases is, that the blow was unexpected, and this agrees with the histories of the ruptures arising from explosions. Artillerymen, for example, who are subjected to explosions of the loudest kind, avert any injury to the drum, if they expect the explosion and prepare for it. Prize-fighters suffer from ear-affections occasioned during fighting, but rupture of the drum is not so common as inflammation of the auricle and meatus, and tumors of the auricle. In such the blows are without doubt much harder, but either from their watching for, and accordingly preparing themselves for the receipt of the blow, or from the form of the hand, which, at the time when it inflicts such blows, allowing the compressed air to escape better, injuries to the auricle more often occur than to the membrane. Besides the injuries to the auricle, meatus, and membrane, injuries to the vestibule and the fenestra ovalis may occur from blows on the ear, setting up pathological conditions which may be quite irremediable. Cases are recorded in which death has occurred, but they are rare. We would impress upon all those whose duties may compel them to inflict corporal chastisement, the necessity of limiting their application to the regions which have ever in England been considered the seats of punishment, and avoiding those in which the pain suffered at the time is not more severe, while the injury inflicted may be far beyond what was contemplated by the giver of the punishment.—*British Medical Journal.*

Gastrotomy.—Dr. Wolzendorff, of Greifswald, has unearthed from the German medical literature the histories of two operations of gastrotomy, performed by German surgeons in the 17th century. The first was performed by Florian Matthis, of Brandenburg, in 1602, and a knife which had been in the stomach fifty-one days was extracted. The knife had an iron blade and a horn handle, and was nine thumbs' breadth (seven inches) in length. Contrary to the expectations of the doctors, the patient recovered. The second operation was performed by Daniel Schwab, the Königsberg lithotomist, in 1635, and a knife which had been forty-three days in the stomach was extracted. The patient recovered.

Treatment of deep Atheromatous Cysts in the Neck.—In those cases in which the extirpation of the cysts is difficult, or is likely to leave an ugly scar, Esmarch recommends that the sac be punctured and washed out with a one per cent. solution of carbolic acid, until the fluid escapes clear, and then Lugol's solution injected and left in for a few minutes. If the cyst has not decreased much in size in six to eight weeks, the operation must be repeated. In six months nothing should remain of the cyst but a small tubercle.

Premature Mental Decay.—Dr. Routh, in his recent work, gives an interesting interview with Dr. Golding Bird six weeks before the death of that gentleman, in which he spoke of his full waiting-room and large professional income as being no matter for congratulation, seeing that he (Dr. B.) felt himself a wreck at a little over forty. "My parting words of advice to you," said Dr. B., "are, never mind at what loss, take your six weeks' holiday."

The British Medical Association.—The meeting of the British Medical Association was held in Sheffield, England, according to announcement, and was a reasonable success. The addresses on medicine and surgery were well received, but the number of papers crowded into the time allotted for the sessions almost precluded the possibility of any discussion upon them.

Original Lectures.

LECTURES ON FEVERS.

By ALFRED L. LOOMIS, M.D.,

PROFESSOR OF PATHOLOGY AND PRACTICAL MEDICINE IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.

(Phonographically reported for THE MEDICAL RECORD.)

LECTURE I.

GENTLEMEN—To-day we will commence the study of those diseases which depend upon morbid conditions of the blood, produced by morbific agents developed exterior to the body of the affected. Such morbific agents may give rise, either directly or indirectly, to morbid processes; either by the changes which they produce in the blood, or by their action on the different organs and tissues of the body to which they are conveyed by the blood-vessels and lymphatics.

The class of morbific agents which will now especially engage our attention may be included under the general head of *viruses*.

By the term virus I mean a morbific substance which is developed either from animal or vegetable tissues in the process of decomposition, or from the excretions of diseased living beings. Many viruses are volatile, and may be conveyed either by air, by fluids, or by solids, and when so conveyed they become the means by which diseases known as contagious or infectious are transmitted. Some viruses are palpable poisons, and may be transmitted from the diseased to the healthy by inoculation.

When the virus which gives rise to a disease has its origin only in a living being, from whom it is excreted in an active state capable of conveyance from one person to another, then the disease which it produces is called contagious, and the virus is called a *contagion*.

If the morbific agent which has the power of developing disease has originated from decomposing organic matter, and has been diffused through the air or water, so that infection may have resulted without contact with one already diseased, the disease is called *miasmatic*, and the virus is called a *miasm*. For instance, intermittent fever is a miasmatic disease, while small-pox and measles are contagious diseases.

With our present knowledge of the nature and origin of viruses, we can make no other classification, except as it is based on their differences of action. We speak of typhus, typhoid, and malarial poisons, but these different poisons have as yet no known physical or chemical properties by which we are able to distinguish one from another. We can only recognize their presence by the peculiar morbid phenomena which each has the power of developing in the animal economy.

The different diseases which are developed by the morbid processes excited by these different viruses are at the present time classed under the head of *infectious diseases*, and the influence of these viruses upon the body is called *infection*. It is also important for you to remember that all of those diseases which are included under the general head of infectious diseases have their own specific morbid product, which will produce these, and only these diseases; and although these different diseases may have very many symptoms in common, and may very closely resemble each other in the phenomena which attend their development, yet the specific character of the morbific agent which has produced them stamps them as distinct diseases. There is reason to believe that not one of this class is of spontaneous origin, but that each depends on its own specific poison. As to the exact nature of such a poison, and its element of power in the production of disease, we have no positive knowledge; at the present time, in regard to it there are two prominent theories.

The *first* is based upon chemical processes; the *second* upon the multiplication of living organisms.

The *chemical theory* maintains that after the infectious element has been received into the blood it acts as a ferment, and gives rise to certain morbid processes upon the principle of catalysis.

The *theory of organisms*, or the germ theory as it is called, maintains that the infectious poisons are living organisms, which, being received into the blood, reproduce themselves indefinitely, and by their reproduction morbid processes are excited which are characteristic of certain types of disease. This is a very seductive theory, and at the present time is quite extensively adopted by medical theorists, as it so readily explains very many remarkable facts connected with the development and reproduction of the class of diseases which are soon to engage our attention. It is readily understood, and there are so many animal poisons which appear to act in this manner, that to one whose opinions are not based upon clinical experience and actual contact with disease, the arguments in its favor are conclusive.

According to this theory all the different forms of disease included under the head of contagious or infectious may be reduced to, or embraced in, two classes.

First, infectious diseases which depend for their development upon a living animal organism. *Second*, those which depend for their production upon a living vegetable organism. Unfortunately for this theory, the special organism of any one of the infectious diseases has never been so plainly described by any one competent observer that all others in the same field of study could with certainty recognize it. The bacterian theory, which recently has so occupied the attention of medical men, especially in Germany, is rapidly being disproved, and consequently as rapidly being abandoned. In this country it can scarcely be held to have ever gained a foothold. It seems to me that one who has watched bacterian development must arrive at the conclusion that bacteria found in connection with the development of disease are the product and not the cause of the diseased process; certain it is that the theory that there exists distinct typhoid, typhus and diphtheritic living germs which are the propagating element of these different diseases, still lacks that proof which will lead the practical physician to adopt it. The question then comes back to us, what is the real nature of those morbific substances which, when received into the human organism, have the power of manifesting phenomena which characterize that class of diseases which we term infectious or contagious. Every day's experience must convince the careful observer that each one of this class of diseases has a distinct producing cause—that the poison of typhus will not produce typhoid fever, neither will the poison of measles develop scarlatina. Although the phenomena which attend the development of these differing diseases may have many points of resemblance, yet each has a distinct origin, that is, has its own specific infection, which specific morbific substance, whenever introduced into the animal economy, either through the skin, respiratory organs or digestive surfaces, interferes in a greater or

less degree with the functions of organic life. This interference is caused either by changes which it produces in the constituents of the blood, or in the solid organs and tissues to which it is conveyed by the blood-vessels and lymphatics.

After reviewing these differing theories and giving careful attention to the facts presented in their support, we arrive at this conclusion—that the exact nature of these morbific agents is unknown. We know that they exist from the diseased action which they produce, and from the manner in which these diseases are propagated we decide that their poisons are distinct from all other poisons, and that each is specific and can reproduce itself to an unlimited extent. The germ theory but explains the phenomena of development. The chemical theory has decided claims on our acceptance, but until our explorations shall have been carried so far as to determine beyond question what is the exact nature of several of these poisons, we shall be compelled to call them unknown morbific agents, governed by certain fixed laws of development and propagation; at the present time investigation in this direction has scarcely begun.

As we pass from the general causation of this group of diseases to their classification, we find ourselves still in doubt. The symptomatic basis of classification of the earlier writers gave place to the more scientific and comprehensive anatomical basis of classification. This for a long period has been almost universally adopted, yet now is giving place to the recent and more definite etiological classification of the present day.

When this group of diseases are classified upon an etiological basis, very naturally they divide themselves into three classes.

First.—A class in which the morbific agent cannot be developed exterior to a living being, but, when developed within the system of one individual, can be transferred to another through the atmosphere. Such is the case in measles, small-pox and typhus fever.

Second.—We have another class called miasmatic or malarial diseases, in which the morbific agent is developed exterior to a physical organization, and cannot be conveyed from one individual to another.

Third.—There is a class in which the morbific agent is developed within, and reproduced exterior to a physical organization. In this class, the poison is developed within the body, but in order to the reproduction it must be deposited in decomposing organic matter exterior to the body; it is then rapidly reproduced, and when received into a healthy organism gives rise to diseased processes. It cannot be directly conveyed from the sick to the healthy, but only through the excrements of the sick, or through decomposing organic matter exterior to the body, with which such excrements must have been in contact. There may be all the elements necessary to its reproduction, such as decomposing animal and vegetable matter, but the disease will not be developed unless there has been added to this decomposing mass, the specific poison of the disease.

The diseases thus developed have been called *miasmatic-contagious*, of which typhoid fever is the best example.

All the different forms of acute contagious miasmatic or miasmatic contagious disease may be either *endemic* or *epidemic*.

They are *epidemic* when they attack a large number of persons at the same time and in the same manner.

They are *endemic* when they are often repeated in the same locality. If they attack individuals without regard to time and place, they are called sporadic.

With this brief introduction, we will enter upon the study of that class of diseases which during the present century have been included under the general head of *fevers*.

Adopting an etiological basis of classification, I shall divide fevers into three classes.

1*st. Contagious Fevers.*—I shall include under this head all of those fevers which depend for their development on a specific morbific agent, which agent must originate in an individual suffering from a like specific disease.

2*d. Miasmatic* or *Malarial Fevers.*—I shall include under this heading all of those fevers which depend for their development on a morbific agent developed exterior to the body, and not connected with any previously diseased physical organization.

3*d. Miasmatic-Contagious Fevers.*—I shall include under this head those fevers which depend upon a morbific agent developed exterior to the body in animal and vegetable decompositions, to which has been added the specific poison of the fever which has had its origin in a diseased physical organization.

The following is the classification which I shall adopt:

1*st Class.*—Contagious Fevers. Typhus Fever, Relapsing Fever, Puerperal Fever, Scarlet Fever, Small-pox, Measles.

2*d Class.*—Malarial or Miasmatic Fevers. Simple Intermittent Fever, simple Remittent Fever, Pernicious Fever.

3*d Class.*—Miasmatic Contagious Fevers. Typhoid Fever, Yellow Fever, Typho-malarial Fever.

The third class of fevers form a connecting link between the first and second class.

In their pathology and clinical histories they have many things in common with each of the other classes, as also in their origin, nature of poison, etc. On this account, and from the fact that during the course of every fever some of the phenomena of typhoid fever are presented, I shall first describe those fevers included in the third class, and shall commence with *typhoid fever*. This is the most universally prevalent of all the fevers. So far as we know, there is no place where it may not be developed and spread. It more frequently prevails in the temperate zone than in the torrid or frigid, but it is possible for it to be developed in all latitudes and in all countries.

This disease, which is essentially the same in all countries, is designated by different names. American writers describe it under the name of typhoid fever. The French call it the typhoid affection, or dothinenteria. English writers describe the same form of disease under the head of enteric fever. The Germans call it abdominal typhus, or gastric fever. I prefer the name typhoid fever, and will commence its history by describing its anatomical lesions.

Morbid Anatomy.—As soon as the disease is fully established, a change in the blood occurs. It becomes darker in color, coagulating imperfectly, the serum being imperfectly separated from the solid constituents, and is of an unnaturally yellow color. The question arises—did these changes take place in the blood prior to the occurrence of the fever, between the exposure and the period of attack. It is certain, that as soon as the characteristic symptoms of the disease are present, the diminution in the fibrin of the blood is in exact proportion to the severity of the fever, and the number of white globules is increased in a similar ratio.

As a consequence of these blood changes, or in connection with them, a series of changes takes place in those organs and tissues of the body in which the processes of waste and repair are most rapidly going on.

These changes are of the nature of parenchymatous degeneration—the essential constituents of the affected organs and tissues being involved.

Similar parenchymatous changes are met with not only in typhoid fever, but to a greater or less extent are characteristic of other fevers and acute infectious diseases.

Spleen.—The organ in which parenchymatous degeneration occurs earliest and most extensively is the spleen.

We find this organ undergoing three distinct changes.

First.—It is increased in size, sometimes enormously. The enlargement commencing soon after the beginning of the disease, and goes on rapidly until the third week, after which it ceases, and after a few days begins to diminish in size. If recovery takes place, by the time it is reached the spleen will have returned to its normal size.

The splenic enlargement is apparently due to congestion and to an increase of normal elements.

Second.—As soon as the spleen reaches its maximum size, its consistency becomes soft; this softening is sometimes so marked that, if a post-mortem be made at the end of the third week, the spleen will present the appearance of a dark, jelly-like mass, which is easily broken down.

Third.—The organ becomes almost black in color, owing to the intense congestion which attends its enlargement, and to the deposit of a brown pigment in its substance.

These changes in the spleen take place in a greater or less degree, in ninety-eight cases out of every hundred.

At the post-mortem of those who have died of typhoid fever, infarctions are sometimes found, although there is nothing peculiar about them. In rare instances, rupture of the spleen occurs without infarctions.

Liver.—Changes in the liver are by no means as common as those in the spleen. The liver may be found presenting its normal appearance, or it may be soft and flabby. When soft and flabby, a microscopic examination shows the liver cells more or less granular and fatty, the nuclei of the cells can no longer be seen, and the degeneration may become so extensive that the outline of the hepatic cells are lost, and nothing but a mass of granules can be seen.

Occasionally there will be found in the liver of those who have died of typhoid fever, small grayish nodules situated along the course of the small veins; these nodules consist of lymphoid cells.

The lining membrane of the gall-bladder sometimes presents evidences of catarrhal or diphtheritic inflammation, when there has been no evidences of its existence during life; cases are recorded where it has been found ulcerated.

Kidneys.—Degenerative changes in the kidneys are of not infrequent occurrence in the course of typhoid fever; they vary in extent with the duration and severity of the fever. When present, they are more marked in the cortical than in the medullary portion of the organ. In some cases they are confined to the epithelial elements, while in other cases degeneration of all the anatomical elements of the organs can be found. Such extensive changes are less liable to occur in typhoid than in typhus fever. Small gray nodules similar to those referred to as occurring in the liver are sometimes found.

If the epithelial degeneration of the cortical substance is extensive, the cells finally break down into a granular detritus, and the cut surface assumes a yellow color and is softer than normal. Infarctions are sometimes met with in the kidneys of those dying of typhoid fever.

Heart.—The parenchymatous changes which take place in the heart are more marked than those in any other organ, for its anatomical elements undergo waste and repair more actively than those of any other organ; and if faulty nutrition is an important element in these degenerative changes, this organ must become very markedly involved.

In a large proportion of cases it becomes soft and flabby, and is of a grayish or brown color. Sometimes it is so much changed that its tissues are easily broken down by moderate pressure; it loses its normal outline, and when removed from the body the walls of its cavities readily fall together. When its muscular tissue is examined microscopically, in many instances it will be found that granular changes, affecting the ultimate muscular fibres, have occurred; this granular muscular degeneration may involve a large portion of the organ, or it may be confined to a few muscular fibres. It may be a general or a localized parenchymatous degeneration. Occasionally the muscular fibres are infiltrated with brown pigment.

If, as is sometimes the case, the heart is firm and friable and its cut surface glistens, the muscular fibres will be found to have undergone a change which closely resembles amyloid degeneration; the muscular fibres will be filled with a material which presents the same shining appearance as the amyloid substance, but on applying the iodine test the same reaction does not take place. It is a form of degeneration which occurs in typhoid fever and is not confined to the muscular tissue of the heart, but is found to a greater or less extent in the voluntary muscles of the body.

Thrombi are sometimes found in the heart, and vegetations adhering to the valves and chordæ tendineæ. These may give rise to infarctions in the different organs of the body. The existence of the degenerative changes in the heart, to which I have referred, may be recognized during the life of the patient, for the heart sounds become feeble according to the extent of the degeneration. In some cases the first sound of the heart will be absent, and it has been claimed that when this phenomenon is present, the use of stimulants in large quantities is indicated.

Lungs.—The lungs undergo changes which have received the name of splenization. This is a form of pulmonary congestion which has received its name from the close resemblance which the affected portion of lung tissue bears to the spleen.

The affected lung tissue is of a darker color than normal, and scattered through its substance will be seen little red or yellowish white points; these little points are scanty blood extravasations.

Lung tissue in a condition of splenization is of a dark reddish blue, brown, or black color; its consistency is firmer than normal, crepitates less freely, has a more uniform, homogeneous appearance upon its cut surface, and is less moist than normal lung tissue; a dark fluid will sometimes ooze from its cut surface, but not as freely as in hyperæmia, and the fluid is more watery in appearance.

A microscopical examination of lung tissue in this condition shows the capillary vessels filled with blood, and the alveoli containing a variable number of cells. In other words, it is a condition closely resembling that condition known as static pneumonia, but no inflammatory process exists; it is simply a stasis in the capillary circulation, accompanied by a slight increase in the cell elements in the alveoli.

Bronchial Tubes.—You will rarely make an autopsy

upon one who has died of typhoid fever, without finding evidences of a more or less extensive catarrhal inflammation affecting the bronchial tubes. So constant is catarrhal bronchitis present in this fever, that Dr. Stokes proposed to call typhoid fever bronchial typhus. In most cases this catarrh is not extensive, affecting only the larger bronchi; it may, however, extend to the smaller tubes and give rise to capillary bronchitis and broncho-pneumonia. Pulmonary infarctions are frequently found in the lungs of those who have died of typhoid fever. They are sometimes quite numerous, are usually of small size, and vary in appearance according to the stage of their development. When recent they are of a dark color, and feel like consolidated lung tissue; later, the color changes to yellow; they may soften and break down.

Larynx.—The larynx, as well as the bronchial tubes, is frequently the seat of catarrhal inflammation; less frequently it is the seat of diphtheritic inflammation. In connection with these laryngeal inflammations, ulcers appear in the larynx; these have received the name of "typhoid ulcers of the larynx;" sometimes they give rise to quite extensive hemorrhages. In connection with, or independent of these laryngeal ulcers, ulceration of the mucous membrane of the mouth and pharynx may occur; at times it involves the epiglottis in such a manner as to clip off its edges. These ulcers may develop on the mucous membrane of the Eustachian tube. In those cases where permanent deafness follows an attack of typhoid fever, usually it will be found due to ulceration of the mucous membrane of the Eustachian tube.

Brain and Nervous System.—As yet we have not been able to determine whether there are any structural changes in the brain or nervous system so constant that they may be regarded as lesions of typhoid fever, although it is reasonable to infer that in a disease where such severe functional disturbances of the cerebro-spinal system exists there must be constant and definite parenchymatous changes. Œdema of the pia mater and of the brain substance, with occasionally quite extensive adhesions of the dura mater to the cranium, not infrequently exist. Punctate extravasations into brain substance are found in a certain number of cases, but even in severe cases they are not always present.

Stomach.—The changes which occur in the stomach are equally important with those that occur in the other internal organs, and are degenerative in their nature. Softening and degeneration of its glandular structure is sometimes so extensive, that if recovery from the fever takes place, a very long time must elapse before the organ can perform its normal function. It is the existence of these degenerative changes that gives rise to the disturbance in digestion which is present in so many cases, not only during the continuance of the fever, but during convalescence.

Muscles.—In addition to the degenerative changes which I have described as occurring in the internal organs in typhoid fever, I must say a word concerning the degenerative changes which so recently have been found almost invariably present in the voluntary muscles. This muscular degeneration is of two varieties: first, a granular degeneration which corresponds to ordinary fatty degeneration. Second, a waxy degeneration, which consists in the conversion of the contractile substance of the primitive bundles into a homogeneous, waxy shining mass. Often both forms of degeneration occur together, sometimes one and sometimes the other predominating.

Progress of Medical Science.

Open Communication of the Ventricles with the Subarachnoidal Spaces.—Profs. Axel Key and Gustave Retzius recall to mind the description which they have given (*Nord Med. Arkiv*, Bdt. 6, No. 5, and *Studien in der Anatomie des Nerven-Systems und des Bindegewebes*)—which were based on direct researches and on injections of the subarachnoidal spaces and the ventricles—of the three apertures (apertura inferior or foramen Magendii, and aperturæ laterales) in the wall of the fourth ventricle. These are apertures by which all the ventricles of the brain are placed in open communication with the sub-arachnoidal spaces. They also refer to their preceding dissertations, which prove that abnormal products in the cerebro-spinal spaces may have their source in the ventricles, and vice versâ.

In the present article, they give the history of a case in which a severe hemorrhage in the ventricles, which occurred during life in a girl twenty-two years of age, previously healthy, caused sudden death. All the ventricles of the brain were filled with coherent clots; the right lateral ventricle, from which the hemorrhage evidently proceeded, was the most strongly distended by them. The clots of the different ventricles communicated with each other by the foramen of Monroe and the Sylvian aqueduct, and from the fourth ventricle the prolongations of the coagulum projected from the ventricle through the three above mentioned apertures, and was immediately continuous with the coagulated blood which was spread out over the base of the brain in all the great subarachnoidal basilar cisterns there located, and which have been described in detail by these authors in the previously mentioned articles. From these cisterns the extravasation of blood was continuous, under the form of a sanguinolent mélange, with the subarachnoidal fluid over the great hemispheres. Below, it extended along the dorsal surface of the spinal medulla, as far as the cauda equina, in the form of a coherent coagulum, but in front the coagulum terminated at the upper portion of the back. With the efferent cerebral nerves the blood continued into the arachnoidal sheaths and into the plasmatic canals described by our authors. Thus it advanced by the arachnoidal sheath of the optic nerve on each side as far as the eyeball; with the auditory nerve to the lamina cribrosa. The motor ocularis communis and its orbital branches presented their plasmatic canals injected with blood, etc.

This case, taken as a whole, thus resembles completely the injections which the authors have obtained with coagulating masses, and which they have described in their large work, previously mentioned. The important point is, that here the injection was produced during life. This proves, obviously, that all the communications described by our authors between the external and internal cerebro-spinal spaces existed during life, and that an abnormal admixture with the cerebro-spinal fluid may extend from one point throughout almost the entire nervous system, and that more than one abnormal condition of a peripherical nerve, as for example, here the injection of the plasmatic canals of the motor ocularis in the orbit, might have its source even in the cerebral ventricles.—*Nordiskt Medicinskt Arkiv*, 8de Bandet, No. 5.

The Chamber of Deputies have voted 13,000 francs, to establish a lectureship on Brain Diseases and Mental Pathology, at the University of Paris.

THE MEDICAL RECORD:

A Weekly Journal of Medicine and Surgery.

WM. WOOD & CO., No. 27 Great Jones St., N. Y.

New York, September 23, 1876.

HOTEL PHYSICIANS AND RURAL PRACTITIONERS.

THE recent letter of a correspondent from Saratoga regarding the relations said to exist between temporary and permanent medical residents of that place, has directed considerable attention to the subject. The correspondent in question makes certain charges which he says he is able and willing to substantiate, while on the other hand an equally trustworthy gentleman denies these charges in toto. From what we know of the physicians who are said to be guilty of unprofessional conduct, we believe that the plaintiff has been misinformed concerning the facts of the case. In any event, it opens a question connected with professional interference one with the other, the discussion of the principle of which may be excusable upon the possibility of the charges being founded upon fact. In any individual interpretation of rights and privileges there is always a tendency to exaggeration, always a temptation to magnify apparent differences of opinion into real and wilful wrongs. But, impartiality of judgment is always best rendered upon the middle ground of conservatism.

Our Saratoga correspondent, upon his own testimony, is certainly wronged by such metropolitans as may come during the harvest of the fashionable season to gather the golden sheaves of hotel patronage, and prevent him from the legitimate exercise of his usual professional privileges. If, as he says, there are some extraordinary means used on the part of the professional visitors to obtain practice, he is perfectly right in complaining. If, as the other side claim, no such means are used, and that the competition is honorable, our correspondent becomes too partial an advocate of what he considers to be his individual rights. We do not pretend to say that he is purposely wrong in his conclusions; but for the sake of using his argument against practices which we know to exist elsewhere, we unhesitatingly endorsed the principle involved in his complaint. As giving us the foundation for some general remarks upon the subject, we are willing to leave Saratoga entirely out of the question, and refer more particularly to other fashionable resorts where such questionable professional practices are quite prevalent.

It is generally conceded that no medical gentleman, because he lives in a certain locality, has the right to monopolize the practice there; to farm the community as if he owned it, and to dispute the right for honorable competition with his peers. A physician who is regularly qualified to practise has a right to ply his profession anywhere and everywhere he pleases, and to change his base of operations as often as it may appear to him desirable. He belongs to the people at large, and has the right and privilege to give his services to any one who may desire it, whether that patient be at Virginia Springs, Saratoga, Newport, Long Branch, Cape May, or any other fashionable resort. The mere fact of the physician being a temporary or permanent resident at any of these places has nothing whatever to do with the question at issue.

While we must be ready to admit that the rural practitioner can hardly look upon this division of labor in a strictly impartial manner, he has no remedy, provided the competition for patronage is strictly honorable. When the latter is not the case, he has a right to stigmatize those who interfere with him as mere travelling quacks.

Medical men of reputation are always in demand everywhere, and are likely to be sought by strangers whether at hotels or any other place. The wider this reputation, the more likelihood for this so-called chance practice. Such men do not need to advertise their presence in hotels, as it becomes a matter of interest to their would-be patrons to discover their whereabouts for themselves. If a patient in a hotel desires to call in such a medical attendant for advice, there can hardly be a question of its propriety. Every medical gentleman, however, admits this. On this score it is very easy to explain why some metropolitan physicians have always plenty to do wherever they may go—entirely irrespective of the presence of resident practitioners. This is as it should be, and is the reward of honest reputations for professional proficiency.

But this can hardly explain the presence of the now so fashionable hotel physician, the temporary appearance of whose sign in the hotel office is a purely business bid for the advantages of the situation. We have yet to learn that these hotel physicians as a class are any more competent than the resident practitioners of the neighborhood. If so, what guarantee have the guests of the hotel of his proficiency in the absence of a well-earned professional reputation in the metropolis? Most of the selections are made on friendly considerations by the hotel proprietors, and there is a distinct business understanding that the said pro-

prietors will make themselves responsible for the fees of the guests by adding them to the board-bill.

There is also an understanding always implied, but not unfrequently expressed, that every effort will be made by the hotel proprietors and their attendants, from the "gentlemanly" clerk to the bootblack, to throw all the possible business of the house into the hands of the regular "hotel doctor." This practice certainly gives great reason for complaint on the part of the physicians resident in the neighborhood against what they have a right to look upon as an unwonted professional monopoly. It is radically wrong, decidedly unprofessional, and positively dishonorable for any medical man to lend his countenance to such practices, even in ever so indirect a manner, to those who, in a business way, desire to be his friends. We regret to say that too many of our transient hotel physicians are of this class, and deserve all the criticism which they are receiving from the so-called country practitioner. While we say that the latter has no right to claim all the practice of his neighborhood, the hotel physician has no more right to monopolize the attendance upon transient visitors. The latter object is so transparent on the part of at least the majority of the hotel physicians, that we have often wondered that any respectable medical man would allow himself to be known as such.

At the risk of being a trifle heterodox in our opinions, we do not see any necessity for having hotel physicians at all. We cannot see why the resident physicians in the neighborhood of the large hotels, except perhaps on extraordinary occasions, cannot attend to all the necessary practice and divide it among themselves. If there are any rights at all in the matter, these gentlemen have the preference to the medical man who merely lives in the hotel during the season for the sake of making what money he can in the shortest possible time. As the case now stands, there is a prejudice on the part of the resident practitioners against the typical hotel physician, which is in the highest degree detrimental to general professional interests. Consultation, as a consequence, is not encouraged, and bitter professional animosities are engendered. The hotel physician is constantly changing from year to year, and has no possible opportunity for acquaintance with his professional brethren in the neighborhood. They are apt to look upon it as a slight, the magnitude of which is not lessened by the circumstances of the unwonted superiority which the new-comer assumes.

There can be no argument in favor of the hotel physician which cannot be made to apply to the average practitioner of the vicinity. In fact, a sense of ordinary fair dealing would concede to the latter all the advantages which might drift in their way, in preference to one whose only real claim to such extra chances are based on a mere business understanding with an hotel proprietor.

Reports of Societies.

INTERNATIONAL MEDICAL CONGRESS.

SECTION OF MEDICINE.

This Section convened Monday afternoon, September 4, 1876, at 3 o'clock, with Dr. Howard in the chair, and Dr. J. Ewing Mears, Secretary. Dr. J. J. Woodward, Surgeon U. S. A., Reporter, read a paper on

"TYPHO-MALARIAL FEVER; IS IT A SPECIAL TYPE OF FEVER?"

After a general introduction, in which he referred to the duration of war as an element of mortality from sickness, and to the statistics of the Prussian army during their last great war, he discussed the subject of camp fevers in our army, especially when complicated with malarial influences. He sketched the history of typho-malarial fever, as reported by different surgeons, and argued that such hybrid combinations were not new in armies, illustrating this with historical facts. He contended that typho-malarial is not a special type of fever; it is no new disease, but a hybrid. He referred at considerable length to those who had sustained his views, and to others who had opposed them.

Dr. Bartholow, of Cincinnati, replied to the charge of acrimony made by the reporter against him. He said he had simply objected to the erection, by Dr. Woodward, of a new type of disease.

Dr. N. S. Davis, of Chicago, said he saw little need of controversy; he was almost surprised that it was necessary to combat the idea of introducing a new disease. The phenomena of this mingling had been common to him. In Chicago, malarial disease was the common form; typhus when it did exist, was imported. In the progress of filling up the city, the malarious influence had gradually disappeared, and for ten years typhoid was gradually on the increase, owing to the peculiar water arrangements. After a time typhus had predominated. To him it was a surprise that any criticism should be made concerning the two diseases being present at the same time. The sooner we recognize this capability for mingling among diseases, the sooner will we clearly recognize and understand the mingling in this case.

Dr. Scott, of Ohio, said he had always lived in a malarious country, and recognized this complexity and union of disease. Early, it was true, this mingling was not so pronounced, but as civilization advanced, it rapidly grew to be so. He thought these discussions were of use, because we do not understand the treatment of the affection. Quinine will not check it, although it can be used to check the malarious condition. He had seen scurvy, while in Nashville, in 1864, in connection with this disease, and he therefore agreed with Dr. Woodward.

Dr. Pepper said he feared the employment of specific terms in such cases, especially as it concerns young men, for it gives rise on their part to a lack of knowledge of the real danger present.

Dr. Reed, of Camden, objected to a term that signifies two specific affections.

On motion, the paper was referred to the Section for publication.

Tuesday, Sept. 5th.—The Section met at 2 P.M.

THE IDENTITY OF CROUP AND DIPHTHERIA.

The first paper was by J. Lewis Smith, M.D., Reporter, physician to the New York Infant's Hospital; subject, "Are Diphtheritic and Pseudo-membranous Croup Identical or Distinct Affections?"

He said the two theories are, first, that the two diseases are distinct; second, that the two are varieties and modifications of one and the same disease. He considered the various causes for believing croup a local malady:—Its causes are the same as in other inflammations which are local; there is a single tract of exudative inflammation in all cases, whereas in a constitutional disease other mucous surfaces would be likely to be inflamed sometimes; and because depressing remedies are tolerated. He gave facts showing diphtheritic laryngitis to be the manifestation of a general malady, such as its long incubative stage in certain cases; its severe constitutional symptoms, in some cases, before appearance of the inflammation; speedy death in certain malignant cases, and important evidence from the state of the kidneys. He next examined into the histological similarity of the two diseases and into the difference in the attendant laryngitis and pseudo-membrane, with an inquiry into the causes of such disease, the age of prevalence, results of treatment, etc.

Dr. Pepper said it was important that there should not be an innumerable number of diseases and disease names. In the present condition of the medical profession diphtheritic and croupal processes distinguish all diseases of the throat. We meet many grades of inflammation in the pharynx, and if we do discriminate thus carefully between these diseases, we must carry the same thing out in the larynx. In mild cases of sporadic pseudo-membranous pharyngitis, sequelæ are rare. Chemically and anatomically he had never been able to discover any difference between the diseases, nor has any microscopic distinction been discerned; constitutionally, also, it was impossible to discover any difference. He cited the fact that in a ward in this city, cases of diphtheria had occurred with at the same time strongly marked cases of croup. As far as treatment is concerned, any difference in effects cannot be taken as distinguishing between diphtheria and croup. Taking a cursory view of the subject, he thinks they are so many forms of the same disease.

Dr. Gibbons, of California, said that although it was contrary to his early teachings, yet he was compelled to learn the two diseases, and he was too old now to try to unlearn it. He thought that should the wheel turn and carry the present ideas down, in twenty years it would turn back again. He quoted two cases which showed a marked difference.

Dr. Woodward agreed with Dr. Pepper, and asked the question, "Whether Dr. Smith had used the first or second edition of Rokitansky's work," as the views did not correspond in the later edition with those previously expressed.

Dr. Hare, of London, drew attention to a paper that had been adopted by the Royal Society of England, to secure opinions on this subject.

Dr. Howard, of Canada, thought we needed a larger number of cases to settle the question; for himself he did not believe in duality of the diseases.

Dr. Holdwith, of Canada, reported some cases showing the duality of the affection.

Dr. Bartholow, of Cincinnati, believed in the duality, and thought the distinction was three fold. Dr. Maddin, of Nashville, expressed similar views, as did Dr. Ayres, of Indiana.

Dr. Harris, of Chicago, thought that we labor too much, as medical men, under the assumption that we have a right to definitely settle such questions. Let us publish our contributions, but let us wait before we decide. After remarks by Dr. Hamilton, of Nova Scotia, Dr. Cohen, of Philadelphia, yielded to Dr. Pepper, who introduced the following resolution:

That in view of the wide diversity of opinion existing in regard to the relationship of diphtheria and croup, the Section prefers to recommend the paper of Dr. J. L. Smith for publication, with an expression of their opinion of its high value as an important contribution to the literature of the subject, but without a definite expression of opinion upon the points at issue.

The motion was finally adopted, and reported to the Congress.

MEDICAL TEACHING.

Prof. A. P. Reid, of Halifax Medical College, Nova Scotia, read a paper on "Medical Teaching."

On motion of Dr. Davis, the Section tendered its thanks to the author, but did not refer it for publication.

Wednesday, Sept. 6th, 1876.—The Section met at 2 P.M. Dr. Stillé, in the chair.

NERVOUS DISEASES AND MODERN LIFE.

Professor Roberts Bartholow, Reporter, of Cincinnati, read a paper on the question, "Do the Conditions of Modern Life favor especially the Development of Nervous Diseases?"

He stated that insanity was frequently alluded to by ancient writers, of which he cited interesting examples; that senile dementia was a subject of judicial inquiry. Numerous references were made in Hippocrates and Galen to insanity and nervous maladies. The social and political state of ancient times were mentioned as an exciting cause of nervous maladies. After alluding to the moral epidemics of mediæval times, the dancing mania, etc., to the epidemics of cerebro-spinal meningitis, etc., he passed to the present state of neurological medicine, possible only after study of general and morbid anatomy and physiology had reached a certain development. Nervous diseases are now better differentiated, more carefully studied.

Statistics of insanity show apparent but not real increase, due to better census returns and better provision for the insane. Improvement in well-being of society results in diminished sickness and mortality rates, greater longevity. It is incredible that nervous centres should exhibit more vulnerability, and other organs of the body greater vigor. Highly probable the brain and nervous system have improved with improvement in other bodily functions.

Dr. Green, commending the paper, said the ancients were, no doubt, well acquainted with these diseases, and yet it was not said as now that they were overstrained. He thought the record afforded by insurance companies, announcing an increase, was due to the fact that more older men insured than formerly. He could not see that over-straining was a predominant cause.

Dr. Gibbons said ancient history did not afford data, for it only recorded the fact of the disease, nor could the statistics from insurance companies be so considered, as these were picked cases. He thought that if Dr. Bartholow had lived in California a few years he would have been impressed with the fact that these cases were on the increase owing to the excitement

arising from dealing in mining stocks, such cases occurring weekly. Many men have no family ties to anchor them, and, therefore, go rapidly to insanity or some other form of mental disease. The opinions expressed in the paper ought to be modified, especially as regards new regions.

Dr. Neftel did not doubt an increase, for these affections were transmitted either in an aggravated or modified form. The brain's intellectual sphere had been enlarged. The child of to-day knows more than did many of the ancients; and as great mental activity produces nervous diseases, there ought to be more now than formerly. The present use of alcoholic drinks is one cause of nervous affections, both directly and indirectly. Syphilis, which is another cause of nervous diseases, did not exist in former times, while it exists largely now. The records of the Pathological Institute of Berlin prove conclusively that many diseases of the brain which lead to death are caused by syphilis. Old physicians always tell us that the disease is increasing; and the fact that the causes producing nervous diseases have increased, ought to convince us that the disease also has increased.

Dr. Maddin agreed with the author of the paper, that there were no new diseases to which man was liable, but because of education and surroundings we had modifications of many diseases. People are different now from what they were two thousand years ago, and he thought our brains now were in a state of hyperæmia, and the stimulated condition of our minds rendered them more liable to disease.

Dr. Duffy, of North Carolina, related two cases which he thought would show that apoplexy was not due to nervous affections.

Dr. Arnold, of Baltimore, thought the specialists were to blame for the introduction of new diseases. He had been in practice thirty years, and he had more cases the latter half of the time, due to the fact of man's race for wealth. Intellectual men are long livers; he believed that shocks in business were worse than hard study. The nervous system always accommodated itself to the strain put upon it. He thought medical men allowed themselves to be governed by the hue and cry of professional temperance orators, for it could not be proved that alcohol had much influence in the production of nervous diseases. Instead of drunkenness being a cause of nervous disease, it was the first herald of its approach.

Dr. Davis said he thought the question could not be determined with any degree of certainty. He had been led to think that very few brains killed themselves by over-work. Physiological law is growth and strength and compactness; if there is not some corroding influence to interfere with the law, they will seldom wear out. Rush tells of a drunken club, the members of which nearly all died of nervous affections. The revolutionary war soon followed, and was a time of excitement, and yet these diseases diminished. It was not mental work that ever produced these affections, but rather troubled digestion, or the system was worn out by other means.

Dr. Howard, of Canada, thought hereditary tendencies wore themselves out, and that if we kept our general system in good form, common nervous affections would not occur.

Dr. Bowditch hoped the section would recommend the publication of the paper, with the statement that they did not vouch for one side or the other of the report, or decide it. Climate had much to do with our capacity for bearing stimulants. English people could not drink as much here as in their own country.

Dr. Green thought suicide could not be laid to nervous affections, as bad humor, love, etc., were more often causes.

Dr. Bartholow then discussed some of these questions. The statement of specialists ought to be taken with allowance; that the increase of their cases was due to their increase of practice. He thought men now were stronger and better than they ever were before.

Dr. Scott, of Ohio, said our modes of travel induced diseases unknown to us before; railway men would not live to the usual age in consequence of their avocation. He thought the custom of sending children to school early a bad one; we take them out when we ought to put them in. Our system of education was a very pernicious one, and we pay too little attention to exercise.

On motion, the paper was referred to the committee for publication.

ETIOLOGY OF EPILEPSY.

Dr. W. B. Neftel, of New York, read a paper on this subject.

After referring to the phenomena of epilepsy artificially produced in the guinea-pig, depending on traumatic reflex paralysis of the cerebral blood-vessels after cerebral commotion, and arguing from this to human epilepsy, the speaker thus summed up his conclusions:

1. It is evident that in a perfectly healthy person, free from hereditary predisposition, epilepsy can be brought on by traumatic influences on the head, causing cerebral commotion, without structural lesion.

2. Further investigations will have to prove that traumatic influences during childhood constitute a most frequent etiological moment in its development.

Dr. Davis moved the paper be referred to the committee for publication.

Thursday, Sept. 7th.—In the absence of the President, Prof. R. P. Howard, of Canada, Vice-Chairman, occupied the chair.

PHTHISIS AND HIGH ALTITUDES.

Dr. Chas. Dennison, of Denver, Colorado, Reporter, then read a paper on "The Influence of High Altitudes on the Progress of Phthisis."

Deductions were drawn from the analysis of sixty-nine years spent by sixty-six consumptives in Colorado, and from corroborative evidence of others, as follows:

1. Cool, dry climates are best. 2. Favorable climatic attributes, such as diathermancy and dryness, are increasingly found with increasing elevation. 3. High altitudes are favorable in incipiency of chronic inflammatory and hemorrhagic cases of phthisis; in others, the more acute the inflammatory process or more active the pulmonary hemorrhage, the more tentative should be the rise in elevation. 4. Partial recovery necessitates permanent residence. 5. High altitudes become unfavorable or negative in proportion as phthisis is complicated with certain forms of cardiac disease, or the stage of "softening" in acute cases, with extensive deposit, or nervous irritability and lack of desirable will power. 6. Early change of climate and mode of life are more positively favorable to cure in a resort to high altitudes. 7. Stimulating effect of high altitudes on respiratory organs is a most important agent in arresting chronic phthisis. 8. High altitude is palliative or curative with or without change of occupation and out-door life. 9. In incipient cases the patient should receive benefit of doubt, in view of

possibility of error in declaring non-existence of phthisis. 10. Resort to a well chosen, elevated climate should form part of a physician's advice to every consumptive, unless specially contraindicated.

Dr. Rosebrugh, of Canada, said another paper was to be read on a like subject, and thought time might be saved by listening to it first. Dr. Dennison objected, and said he had left out everything that referred to the other subject.

Dr. Duffy, of North Carolina, thought the question of moist atmosphere important. He had seen coughs contracted in dry weather yielding in moist. Habits of life had much to do with the contraction of consumption; outside of his State people shut the doors too much, instead of putting on more clothes. There was little danger from sudden changes provided the system was all right. The air in California is heavily laden with moisture, and that has much to do with the freedom from consumption, or at least did not add to its prevalence.

Dr. Baldwin, of Florida, said he had been interested in the subject for thirty-eight years in his own State. He doubted the beneficial results of altitude, because in Florida good results were obtained even below the level of the sea. Consumption had really been cured; he knew this from post-mortem examinations; the change did this. He spoke of oxygen being considered a panacea, and doubted very much its efficacy. The effort necessary to get this oxygen militated against its value. It could be gotten in Florida with much less trouble than in Colorado. Rest was of the greatest use. Sudden changes such as we see on the plains of the West, even to the extent of sixty degrees in a day, can never be good; in Florida this change is about fourteen degrees.

Dr. Gibbons desired to know if out-door life was associated in the treatment. Dr. Dennison replied that it was. Dr. Gibbons thought the reporter's conclusions were warped by local feelings; the ideas expressed were different from those given him in a letter received not long ago. The statement that California had a moist climate was unfounded; it was absolutely dry. He had looked for cases of consumption, but had failed to find them; he thought this due to the equable climate. There were plenty of climates in California, one every ten miles. He prescribed when a patient came to him, "to get on a horse and look out for a climate for himself."

After remarks by Dr. Baldwin and Dr. Stewart, of Minnesota, Dr. Gibbons, of California, moved the same resolution be adopted in regard to this paper as was adopted in that of Dr. Bartholow, which was agreed to.

Dr. Henry MacCormac, of Belfast, Ireland, being absent, the Secretary read his paper on "The Open-Air Treatment of Consumption." The paper contended that all tubercular deposits, no matter where situated, are ascribable to habitual respiration of air already breathed, proof being given, to the writer's satisfaction, from observation and chemical analysis. He said that tubercle is only the effete waste of the animal organism; when effete tissue is not oxidized, it is not expelled as carbonic acid. No other theory, no other treatment than open air, was, in his view, tenable.

Dr. Edge, of Camden, believed in the medium as to altitudes.

Dr. Madden, of Tennessee, thought we ought to give more attention to the stomach. He believed if the patient could digest oily matters he would be better.

Dr. Davis said he could not understand the law of logic or the law of nature, exhibited by sending a patient on horseback out into the open air to breathe more oxygen, and at the same time to give him more alcohol which consumes the oxygen.

He then offered a resolution to refer Dr. MacCormac's paper back to the author on account of its very dogmatic character, which was carried.

The discussion of the previous paper was then resumed.

Dr. Johnson, of Illinois, said he had known consumptives recover that went to Colorado, Florida, North Carolina, Georgia, Tennessee, the south of France, etc., etc. They all came back enthusiastic over the change of scene and climate. It seemed they had all had good food and exercise, etc. The idea of introducing altitude into the discussion was perhaps unnecessary, but it was a fact that cases in the early stage were benefited. Those in the second stage need a warm climate.

Dr. Hare, of London, thanking the author for his observations, mentioned the fact that in Iceland and Norway consumption did not exist. He wished the doctor to continue his observations. He objected to the use of alcohol because it induced drunkenness.

Dr. Davis joined with the last speaker in the hope that Dr. Dennison would continue his observations. He then moved that the resolution in reference to Dr. Dennison's paper, which had been laid on the table, be taken up for consideration.

A member from New Jersey asked Dr. Dennison whether his paper took into consideration the physical advantage of living in a high altitude?

Dr. Dennison said he had; he had not read all of the paper; the omitted portion would reply to many of the points mentioned.

Dr. Howard, the Chairman, was personally interested in the paper, and quite agreed with some of the other speakers, that there were not similar papers written by people living in a higher altitude.

Friday, September 8th. — The Section met at 2 o'clock, President Stillé in the chair.

ULCERS OF THE STOMACH.

Dr. Charles W. Dulles, of Philadelphia, read a paper translated by him from the French of Dr. H. Lebert, formerly Professor of Clinical Medicine at Zurich and at Breslau, on the "Treatment of Simple Ulcer of the Stomach."

Dr. O'Hara spoke especially of boiled milk in the treatment of the disease.

The President, in reply to certain remarks, said the disease was very frequent, more so than is usually supposed. Speaking of the use of concentrated milk, he said that some people could only digest cold victuals. One case was benefited, although the case was not, it seems, clearly diagnosed, by milk and lime water, but this eventually failed. When on a trip to Germany absolutely cold food was prescribed, and the patient recovered. The food must be made cold by ice.

Dr. Gibbons, of California, spoke of the treatment by opium and bismuth, and also with nitrate or oxide of silver.

Dr. O'Hara referred to the use of condensed milk, and in another case milk warm from the cow was beneficial.

Dr. Smith, of Iowa, spoke of shaved ice as proving successful in one case.

Dr. Mason, of New York, said that milk with the water evaporated out had also been successful.

The subject was referred for publication.

PROGRESSIVE PERNICIOUS ANÆMIA.

Dr. Howard, of Montreal, read a paper on this subject, with observations upon the ante- and post-mortem conditions observed in that affection. Having reported four cases of the disease observed by himself, he analyzed the circumstances under which sixty-two examples of the affection occurred, arranging them under the heads of pregnancy, parturition, chlorosis, chronic diarrhœa, blood-waste, dyspepsia, extreme poverty or poor diet, jaundice, and "failing health." The post-mortem appearances in fifty-one autopsies are reviewed, with observations on microscopic characters of the blood regarded by Eichorst as diagnostic, and the paper terminates with the following conclusions:

1st. The various forms of anæmia may occasionally take on progressive and pernicious characters. 2d. Such is frequently the case with anæmia of pregnancy and parturition; the converse is true of chlorosis. 3d. A distinct variety of anæmia, having etiology and pathogeny peculiar to itself, "progressive pernicious," is not proven. 4th. Neither spleen nor lymphatic glands usually present any, much less any special lesion in pernicious anæmia. 5th. It remains to be proved that hyperplasia or other change of the bone marrow is a cause of anæmia. 6th. If it be a cause, it has yet to be shown whether it is the cause of a variety that should be especially styled pernicious and progressive, the weight of evidence appearing to be opposed to it. 7th. It is premature to regard pernicious anæmia as a myelogenous pseudo-leukæmia. 8th. Pernicious anæmia is perhaps rather more frequent in females than in males, but the difference is not very great.

Dr. Davis, of Chicago, said he should feel disposed to hold in entire abeyance the view that there is an especial disease called "progressive pernicious anæmia." In one case in which no post mortem was obtained, the blood, on examination, showed a very few red blood-corpuscles, with an abundance of white ones. But there may be a class of affections in which the blood is materially changed. The office of the red cells is not perfectly understood, and therefore we cannot appreciate the disease.

On motion, the paper was referred to the committee for publication.

ALCOHOL AS FOOD AND MEDICINE.

The next paper was by Dr. Ezra M. Hunt, of Metuchen, N. J., on "Alcohol in its Therapeutic Relations as a Food and a Medicine."

The paper reviews its claims as a food and a medicine, and the arguments pro and con adduced in regard thereto. The author examines the experiments of Duroy, Binz, Rickards, Parkes, Anstie, Hammond, Richardson, and others, and the testimonies as to its thermic nutrient and molecular effects. Facts are adduced to show that present methods of prescribing alcohol secure neither uniformity nor accuracy. From the amount of imitation and of artificial manufacture, would it not be better the medicinal article should always be artificially prepared, and certified by manufacturers? The whole subject of alcohol, and the different effects of members of the alcohol series, should be carefully restudied. Differences of result are really often differences in the kind and quantity of alcohol contained.

(The writer's conclusions will be found in the report of Saturday's general session.)

The paper was referred to the committee for publication.

SCLEROSIS OF THE LUNG.

Prof. Rudnew, of St. Petersburg, Russia, read a paper on "Sclerosis of the Vessels of the Lung," by Dr. Beresnewitsch, of the Institution of Pathological Anatomy at St. Petersburg. The atheromatous process has been described by some writers, as affecting branches of the lung arteries, with heart complications, or, when the lungs are themselves affected, with atrophy or emphysema. Dr. B. argues that emphysema was the sequence rather than the cause. His inquiries, based on microscopical investigations, are: 1. What arteries are directly affected, whether bronchial or pulmonary? 2. Under what conditions is the disease generated? Dr. Isaacson had found it was always due to an affection of the lung-vessels. Dr. B. describes the changes which take place in the blood-vessels, and ascribes much of the destructive action to syphilitic infection in the capillaries, and afterwards in the larger arteries. Sclerosis is due to development of connective tissues, between the layers of which the coating consists.

The paper was referred to the committee for publication.

The Section then adjourned *sine die*.

SECTION OF SURGERY.

The Section held its first session, Monday, September 4th. Prof. Joseph Lister, of Edinburgh, in the chair; Dr. J. H. Packard, of Philadelphia, Secretary.

Prof. Lister, after acknowledging the honor, and paying a compliment to American surgeons and to Philadelphia, and referring to the numerous original operations first performed in this country, stated that he had been influenced in his decision to visit this country by seeing on the programme of the Congress mention of a proposed discussion on antiseptic surgery.

ANTISEPTIC SURGERY.

Prof. John T. Hodgen, of St. Louis, Reporter, read a paper on this subject. The propositions discussed by him were the following:

1. Putrefaction may and does occur in the solids and liquids of the body both with and without the direct contact of germs borne in the air or water.

2. Putrefaction of the solids and liquids of an open wound may in many cases be prevented if the contact of living germs with the surface is not permitted, or by destroying their vitality after contact with it.

3. It is possible that the living solids and liquids of the body may be so altered that they shall not furnish the conditions necessary to putrefaction.

4. Practically, the conditions to be met in preventing putrefaction are so difficult, that in many cases it is impossible to comply with them. Yet, even partial success is eminently worthy of our best efforts.
